# ROYAL COMMISSION ON METROPOLITAN SEWAGE DISCHARGE.

# FIRST REPORT

OF

# THE COMMISSIONERS.

**Presented to both Houses of Parliament by Command of Her Majesty.**

LONDON:
PRINTED BY EYRE AND SPOTTISWOODE.

To be purchased, either directly or through any Bookseller, from any of the following Agents, viz.,
Messrs. HANSARD and SON, 13, Great Queen Street, W.C., and 32, Abingdon Street, Westminster;
Messrs. EYRE and SPOTTISWOODE, East Harding Street, Fleet Street, and Sale Office, House of Lords;
Messrs. ADAM and CHARLES BLACK, of Edinburgh;
Messrs. ALEXANDER THOM and Co., or Messrs. HODGES, FIGGIS, and Co., of Dublin.

1884.

[C.—3842.] *Price 9d.*

# ORIGINAL COMMISSION.

*VICTORIA, R.*

**Victoria,** by the Grace of God of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith, to Our right trusty and well-beloved Councillor George William Wilshere, Baron Bramwell; Our trusty and well-beloved Sir John Coode, Knight, Member of the Council of the Institution of Civil Engineers; Our trusty and well-beloved Alexander William Williamson, Esq., Doctor of Laws, Doctor of Philosophy, Fellow of the Royal Society, Professor of Chemistry in the University College, London; Our trusty and well-beloved Francis Stephen Bennet François de Chaumont, Esq., Retired Surgeon-Major in Our Army, Doctor of Medicine, Fellow of the Royal Society; Our trusty and well-beloved Thomas Stevenson, Esq., Doctor of Medicine; and Our trusty and well-beloved James Abernethy, Esq., Fellow of the Royal Society of Edinburgh, Member of the Institution of Civil Engineers, Greeting:

**Whereas** We have deemed it expedient that a Commission should forthwith issue to inquire into and report upon the system under which sewage is discharged into the Thames by the Metropolitan Board of Works, whether any evil effects result therefrom, and in that case what measures can be applied for remedying or preventing the same:

**Now know ye** that We, reposing great trust and confidence in your knowledge and ability, have authorised and appointed, and do by these presents authorise and appoint, you, the said George William Wilshere, Baron Bramwell, Sir John Coode, Alexander William Williamson, Francis Stephen Bennet François de Chaumont, Thomas Stevenson, and James Abernethy, to be Our Commissioners for the purposes aforesaid.

**And** for the better effecting the purposes of this Our Commission, We do by these presents give and grant unto you, or any three or more of you, full power to call before you such persons as you shall judge likely to afford you any information upon the subject of this Our Commission; and also to call for, have access to, and examine all such books, documents, registers, and records, as may afford you the fullest information on the subject, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

**And** We do further by these presents authorise and empower you, or any three or more of you, to visit and personally inspect such places as you may deem expedient for the more effectual carrying out of the purposes aforesaid.

**And** We do by these presents will and ordain that this Our Commission shall continue in full force and virtue, and that you, Our said Commissioners, or any three or more of you, may from time to time proceed in the execution thereof and of every matter and thing therein contained, although the same be not continued from time to time by adjournment.

**And** We further ordain that you, or any three or more of you, may have liberty to report your proceedings under this Our Commission, from time to time, if you shall judge it expedient so to do.

And Our further will and pleasure is, that you do, with as little delay as possible, report to Us, under your hands and seals, or under the hands and seals of any three or more of you, your opinion upon the several matters herein submitted for your consideration.

And for the purpose of aiding you in such matters We hereby appoint Our trusty and well-beloved William Pole, Esq., Fellow of the Royal Society and Fellow of the Royal Society of Edinburgh, Member of the Council of the Institution of Civil Engineers, to be Secretary to this Our Commission.

Given at Our Court at Saint James's, the twenty-second day of June, one thousand eight hundred and eighty-two, in the forty-sixth year of Our reign.

By Her Majesty's Command,
W. V. Harcourt.

---

## SUPPLEMENTARY COMMISSION.

*VICTORIA, R.*

Victoria, by the Grace of God of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith, to Our trusty and well-beloved Sir Peter Benson Maxwell, Knight; and Our trusty and well-beloved Charles Brisbane Ewart, Esquire, Companion of Our most Honourable Order of the Bath, a Colonel in Our Corps of Royal Engineers, Greeting:

Whereas We did by Warrant under Our Royal Sign Manual, bearing date the twenty-second day of June, one thousand eight hundred and eighty-two, appoint Our right trusty and well-beloved Councillor William Wilshere, Baron Bramwell, together with the several gentlemen therein mentioned, or any three or more of them, to be Our Commissioners to inquire into and report upon the system under which sewage is discharged into the Thames by the Metropolitan Board of Works, whether any evil effects result therefrom, and in that case what measures can be applied for remedying or preventing the same.

Now know ye that We, reposing great trust and confidence in your zeal, discretion, and ability, have authorised and appointed, and do by these presents authorise and appoint, you, the said Sir Peter Benson Maxwell and Charles Brisbane Ewart, to be Our Commissioners for the purposes aforesaid in addition to and together with the Commissioners whom We have already appointed by the before-mentioned Royal Warrant.

Given at Our Court at Saint James's, the first day of November, one thousand eight hundred and eighty-two, in the forty-sixth year of Our reign.

By Her Majesty's Command,
W. V. Harcourt.

# CONTENTS OF THE FIRST REPORT.

PAR.

1. Introductory.
2. Three subjects of inquiry.
3. Limitation of the inquiry, in the first instance, to the first two of these.
4. General nature and conduct of the proceedings of the Commissioners. Parties appearing.
5. Divisions of the present Report.

PART I.

HISTORICAL NOTICE IN REGARD TO THE DRAINAGE OF LONDON.

EARLY HISTORY DOWN TO 1830.

6. The original object of sewers was only to carry away the rain water.
7. Early legislation in regard to them.
8. Introduction of water-closets; their connexion with the drains and sewers.

EARLY SCHEMES, 1830–1846.

9. Pollution of the Thames. John Martin's proposed plan of embankments and intercepting main sewers.
10. Other schemes.

COMMISSIONS OF SEWERS TO 1847.

11. The drainage of the metropolis was under the charge of eight local and independent Commissions.
12. Evils of divided management.

CONSOLIDATED COMMISSION, 1848 TO 1855.

13. Act of Consolidation.
14. Power and functions of the body.
15. First Commission.
16. Second Commission. Competitive designs for main drainage.
17. Third Commission. Appointment of Mr. Frank Forster as Engineer.
18. His plans for the main drainage.
19. Fourth Commission.
20. Fifth Commission. Bazalgette and Haywood's plans.
21. Suggestions of the Board of Health. Sixth Commission.
22. Abolition of cesspools. Foul state of the Thames.
23. Inefficiency of the Drainage Authority. Its supercession.

THE PLANS OF THE METROPOLITAN BOARD OF WORKS, 1856.

24. Power and duties of the Board.
25. First plan.
26. Its submission to the Commisssioners of Her Majesty's Works. Question as to position of outfalls.
27. Second Plan.
28. Third Plan. Reference by Government of the whole subject to three engineers.

THE INQUIRY OF THE GOVERNMENT REFEREES, 1857.

PAR.

29. Instructions.
30. Report.
31. Sewage and rainfall to be provided for.
32. Position of outfalls proposed by the Metropolitan Board.
33. Plan of the Referees.
34. Proposal to remove the outfalls lower down the river.
35. Main outfall channels.
36. Storm overflows.
37. Estimate of cost.
38. Possible utilization or deodorization of the sewage.
39. Conclusion.
40. Appendices.

DISCUSSIONS OF THE SUBJECT, 1857–8.

41. Objections to the Referees' scheme. Replies and rejoinders.
42. Submission of the subject, by the Metropolitan Board, to Messrs. Bidder, Hawksley, and Bazalgette.

REPORT OF MESSRS. BIDDER, HAWKSLEY, AND BAZALGETTE, 1858.

43. General contents.
44. Examination of Referees' report.
45. Sewage and rainfall; area to be drained; condition of river; internal drainage.
46. Position of outfalls.
47. Estimate of cost.
48. Conclusions.
49. Extracts from Appendices.
50. Answer by the Referees, and rejoinders.

STATE OF THE THAMES, 1858.

51. Statements in Parliament. Temporary remedial measures.

ALTERATION OF THE LAW AND CONSTRUCTION OF THE MAIN DRAINAGE WORKS, 1858–1875.

52. Change of Government. Action of the Metropolitan Board. Negotiations with the First Commissioner of Works. Change of Ministerial policy.
53. Act of 1858, giving greater powers to the Metropolitan Board.
54. Probable reasons which influenced the change. State of the river;—general approval of the principles of interception;—the Board's plans not necessarily final;—confident expectation that some process of deodorization would be used.
55. Construction of the Main Drainage Works.

ENLARGEMENTS FOUND NECESSARY, 1881–82.

56. New storm relief sewers. Enlargement of reservoirs.

THE THAMES EMBANKMENT, 1860–1874.

PAR.
57. Its necessity. Acts of Parliament. Construction.

ATTEMPTS TO UTILIZE THE SEWAGE, 1860 to 1873.

58. Discussions and considerations. Advertisements for competitive plans.
59. Hope and Napier's proposals. The Essex Reclamation Scheme.
60. Sewage from south side. Trials of the "Native Guano Company."

FORMER PUBLIC INQUIRIES AS TO ALLEGED EVILS RESULTING FROM THE SEWAGE DISCHARGE.

61. Mr. Rawlinson's Barking Inquiry, 1868.
62. The Thames Conservancy Mud-bank Inquiries, 1867–80.

PART II.

THE SYSTEM UNDER WHICH SEWAGE IS DISCHARGED INTO THE THAMES BY THE METROPOLITAN BOARD OF WORKS.

63. Introductory.

GENERAL PRINCIPLE.

64. System of interception.

NORTHERN INTERCEPTION.

65. High, middle, and low level main sewers. Northern outfall sewer.

SOUTHERN INTERCEPTION.

66. High and low level main sewers. Southern outfall sewer.
67. Table showing magnitudes and dimensions.

ARRANGEMENTS AT THE MAIN OUTFALLS.

68. Reservoirs at Barking Creek and Crossness; their dimensions and working.

CAPACITY OF THE MAIN SEWERS FOR DISCHARGE.

69. Double nature of the work to be done. Sewage proper and rainfall.
70. The "separate system" not applicable to London.
71. Combination of the sewage and rainfall in one system.
72. Quantities actually discharged, and discharging capacities.

STORM OVERFLOWS.

73. Necessity for, and general nature of these.

COST.

74. Amount expended and to be expended on the main drainage works.

REMARKS.

75. Credit due to the Metropolitan Board and to their engineer in regard to the main drainage works.
76. Benefits to the metropolis.
77. Weak points of the system. The storm outlets.
78. The discharges from these are frequent and considerable, and occasionally of very offensive character. Evidence of this.

PAR.
79. No evidence of positive evils arising from these discharges; but they may increase hereafter so as to be objectionable.
80. Discharge of the sewage in its crude state. Deodorization originally contemplated; this subject belongs to the third head of inquiry.

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER.

81. Quantity of sewage proper discharged.
82. General nature of the problems of distribution.
83. Tidal currents and oscillation.
84. Circumstances of discharge at the main outfalls.
85. Gradual displacement, and progress of the sewage down the river.
86. Mixing action. Mixing of sea water, fresh land water, and sewage.
87. Chlorine test. Results shown thereby.
88. Accumulation of the sewage. Its dilution by fresh and sea water.
89. Effect of the mixing action on the permanent progress of the sewage out of the river.
90. Disadvantage of the mixing action.
91. Answer of the Metropolitan Board to these objections to their system.

PART III.

WHETHER ANY EVILS RESULT FROM THE SYSTEM UNDER WHICH SEWAGE IS DISCHARGED INTO THE THAMES BY THE METROPOLITAN BOARD OF WORKS.

92. Classification under five heads.

(A.)

INJURY TO THE HEALTHINESS OF THE DISTRICTS IN THE NEIGHBOURHOOD OF THE RIVER.

93. Complaints made.
94. Evidence received.
95. No serious injury to health substantiated.
96. But there is evidence of affections of a slighter kind.
97. Conclusions from this.

(B.)

GENERAL NUISANCE AND INCONVENIENCE FROM THE POLLUTION OF THE RIVER.

98. Limitation to the consideration of the circumstances occurring near the main outfalls.
99. General facts of the case.
100. Evidence upon it.

*Popular Evidence.*

101. Complaints made before the appointment of this Commission.
102. Evidence offered on this inquiry on behalf of the complainants.
103. As to the foul state of the water.
104. As to the deposit of foul mud.
105. Additional evidence offered.
106. Evidence, in answer, offered by the respondents as to the foul state of the water.
107. As to the foul mud.
108. Inspections by the Commission.

*Scientific Evidence.*

109. General nature of such evidence.
110. Scientific witnesses.
111. Results of chemical examinations.

*Remarks.*

PAR.
112. Overwhelming amount of evidence as to the facts of the nuisance.
113. Answers of the respondents to this evidence. Opinions of the Commission thereon.
114. Magnitude of the causes in action.
115. Nuisances confined to the river or its immediate neighbourhood.

(C.)

INJURY TO FISH.

116. Testimony of witnesses.
117. Alleged causes of the injury. Opinion of the Commission.

(D.)

POLLUTION OF WELLS NEAR THE RIVER.

118. Alleged danger.
119. Evidence on the point.
120. Answer of the respondents. Opinion of the Commission.

(E.)

THE FORMATION OF SHOALS OR BANKS WHICH MIGHT PREJUDICE THE NAVIGATION OF THE RIVER.

PAR.
121. Fears on this subject.
122. Previous inquiries. The Barking proceedings.
123. The Mud-bank Arbitration.
124. Opinion of the Commission.

CONCLUSIONS.

125. Summary of the general conclusions at which the Commission have arrived in regard to the first two subjects of their inquiry.

# FIRST REPORT.

TO THE QUEEN'S MOST EXCELLENT MAJESTY.

MAY IT PLEASE YOUR MAJESTY,

1. WE, the Commissioners appointed by Your Majesty for the purpose of inquiring into the effects of the discharge of the Sewage of the Metropolis into the River Thames, humbly report to Your Majesty, as follows.

2. Your Majesty's instructions to us have directed our attention to three distinct subjects of inquiry, viz.:

(1.) "The system under which Sewage is discharged into the Thames by the Metropolitan Board of Works;"

(2.) "Whether any evil effects result therefrom;" and,

(3.) "In that case, what measures can be applied for remedying or preventing the same."

3. At an early period of our proceedings we determined that it would be expedient to limit the inquiry, in the first instance, to the first two of these subjects, as the consideration of the third must be dependent on the conclusion we should arrive at in regard to the second. And we believed that if we should find any such evil effects existing, it would be advisable to afford opportunity for the consideration and suggestion of remedies.

We have now formed the opinion, that the discharge of the sewage does produce certain evil effects of sufficient importance to justify us in entering upon the third head of inquiry; but before doing so we think it right, for the reason we have mentioned, humbly to present to Your Majesty a full Report of our proceedings hitherto.

4. After receiving from Your Majesty's Secretary of State for the Home Department various papers directing our attention to the complaints that had been made of the state of the river, we invited evidence on the matter, and the following parties appeared before us.

*As Complainants.*

The Corporation of London (as Port Sanitary Authority).
The Thames Conservancy Board.
A "General Committee for the protection of the lower Thames from pollution."
The Erith Local Board, and some other local authorities and bodies.

*As Respondents.*

The Metropolitan Board of Works.

At the outset of the proceedings the Metropolitan Board of Works applied for leave to attend the inquiry by counsel; and as it appeared to us that the matter had the character of a complaint, and a denial of the truth of that complaint, and that there would be a difference on the facts presented to us, involving examination and cross-examination which could best be conducted by the respective parties, we thought it right, in the interest of our inquiry, to admit the attendance of Counsel for those parties who thought fit to avail themselves of their assistance. Counsel have accordingly attended on behalf of each of the parties above named, except the Thames Conservancy Board.

We have now held in all fifty-nine meetings, at forty-six of which the parties were in attendance. During these 126 witnesses have given evidence, some at great length, their examination and cross-examination having been undertaken by able counsel. A large body of persons, of various classes in life, have testified to the facts, while the scientific aspects of the case have been presented to us by eminent engineers, chemists, medical men, and others. The case has been further illustrated, on both sides, by the production of a large number of plans, tables, and other documents, prepared in most elaborate detail.

5. As the subjects brought before the Commission have often been discussed at previous times, it may be useful to give a notice of the more important proceedings that have taken place in regard to the drainage of the Metropolis, and of the views that have from time to time been entertained thereon.

Our present Report may, therefore, be conveniently divided under three heads.

## PART I.

HISTORICAL NOTICE IN REGARD TO THE DRAINAGE OF LONDON.

## PART II.

THE SYSTEM UNDER WHICH SEWAGE IS DISCHARGED INTO THE THAMES BY THE METROPOLITAN BOARD OF WORKS.

## PART III.

WHETHER ANY EVIL EFFECTS RESULT THEREFROM.

# PART I.

## HISTORICAL NOTICE IN REGARD TO THE DRAINAGE OF LONDON.

### Early History down to 1830.

6. The most important feature of modern town drainage, namely, the removal of the house sewage by water in the drains, is of very late introduction.

As the area of the metropolis was gradually covered with buildings, sewers became necessary; but they were originally intended only to cover or supply the place of natural streams and ditches, and so to carry away the rainfall from the fields, roads, and roofs of the houses.

7. The subject of drainage in this sense had attracted the attention of the British Legislature at an early period. As far back as 9 Henry III., 6 & 8 Henry VI., 4 Henry VII., and 6 Henry VIII., statutes were made for the purpose of partially regulating the conditions under which works were to be executed. These acts, however, were of but a local nature; the first measure of a general character was the celebrated "Bill of Sewers," which was passed in the 23rd year of the reign of Henry VIII., 1531, cap. 5., and which appears to have laid the foundation of modern legislation in the class of works now under consideration.

Subsequently to this Act there were others by which the original Bill of Sewers was continued, amended, and explained. These measures were usually applicable to the country in general; but in the metropolis, owing to the rapid increase of buildings, the legislature was obliged to intervene more frequently, in order "to render more "effective the powers granted by previous Acts of Parliament for making, enlarging, "amending, and cleansing the vaults, drains, and sewers, within the City of London "and the liberties thereof."

A curious paper written by Sir Christopher Wren in 1678, and still preserved in M.S., proposed some important improvements in regard to "y$^{e}$ new sewers," "and "y$^{e}$ back waters in St. Margaretts, Westminster."*

The creation of new quarters of the town, themselves larger than the city, and the peculiar constitution of the local government bodies, led to a subdivision of the districts, and consequently of the management of their underground drainage; and in the eighteenth century the legislative Acts became more frequent.

In 1732, the River Fleet, which previously had been a navigable stream, was covered in, and by Act of Parliament formed into a sewer, below Holborn. The Ranelagh and the King's Scholars Pond sewers, and other important arterial drains, were also closed in about the same period.

At the beginning of the present century it was penal to discharge sewage or other offensive matter into the sewers, which were regarded as the legitimate channels for surface waters only. All offensive house refuse was collected into *cesspools*, the contents of which were removed from time to time, and carted away for use in the country as manure.

8. About 1810, an invention was introduced which had a very important effect on the drainage system, namely, the *watercloset*. Its adoption was at first slow, but its advantages in promoting domestic cleanliness became gradually appreciated by the public, and after 1830 its progress became rapid and remarkable.

The waterclosets were originally made to discharge into the cesspools; but the large addition caused to their contents in this way rendered it necessary to introduce overflow drains from them running into the street sewers. But as buildings increased, and cesspools became more numerous, they were found, particularly when badly constructed or neglected, to be sources of annoyance, discomfort, and disease; and as the invention of the watercloset offered facilities before unknown for the entire removal of the

* See a paper by Sir Joseph Bazalgette on the Main Drainage of London, Min. Proc. Inst. C. E., Vol. xxiv., 1864-65.

sewage, it became the practice to discharge it, with the aid of a sufficient water supply, into the street sewers, from which it was conducted into the River Thames.

The effect of this change was to pollute the sewers, and to render it necessary to cover such of them as had before been left open; but on the other hand there was this advantage, that the natural flow of the streams became largely aided by the artificial water supply passing from the houses, which tended to keep the sewers clean.

## Early Schemes.—1830–1846.

9. It was soon perceived that the purity of the Thames would be materially affected by this change; and the matter attracted considerable attention, owing to the fact that the water supply of the metropolis was largely drawn from the river within the tideway;—a state of things that was not wholly abolished till about the year 1855.

As early as 1834 the idea arose that, while still retaining the advantages of sewer drainage, it would be possible to carry off the refuse by *the principle of interception*, without polluting the river in the neighbourhood of London. The originator of this idea was the celebrated painter John Martin. In June of that year he designed a plan, according to which it was proposed to embank both sides of the river Thames, and to construct an intercepting sewer in each embankment, for the purpose of collecting the sewage, and conveying it to points in the river below the most populous part of London. The plan excited considerable attention; its details appear to have been studied with some care, and a committee of gentlemen was appointed to examine it;* but it was in advance of the time, and as serious objections were urged against it, it was not proceeded with. At the same time, as it formed such a striking anticipation of the plan ultimately adopted, it deserves a mention in history.

10. Other proposals followed, particularly one in 1845 by Mr. Thomas Wicksteed (then engineer of the East London Waterworks Company) who renewed Martin's interception proposal, carrying the points of outfall down to Barking Creek on the north and to Greenwich Marshes on the south side, adding provisions for deodorizing the sewage by chemical means, before its discharge.†

In 1846 a company was established under an Act of Parliament for collecting sewage directly from some of the principal London sewers, and utilizing it upon land in the country; but the attempt proved a failure, and was soon abandoned.

## Commissions of Sewers to 1847.

11. The drainage of the metropolis was at this time under the charge of separate local "Commissions of Sewers." In 1847 there were no less than eight of these bodies, each exercising an independent sway over its own district.

These were—

The City of London.
Westminster and part of Middlesex.
Holborn and Finsbury.
The Tower Hamlets.
St. Katherine.
Poplar and Blackwall.
Greenwich.
Surrey and Kent.

Each consisted of a Board with almost unlimited powers over its own district; with its own peculiar mode of conducting business; with a special staff of engineers or surveyors, clerks, superintendents, &c., &c.; and each with its own peculiar regulations as to the sizes of drains, their rates of inclination, mode of execution, and cost.

12. Under such a divided management it was hardly possible that any advantageous general principles of drainage could be acted on. No uniform system was observed either as to the dimensions of the main sewers, or their rate of fall; nor was any attempt made to conform the works of the several districts to any one general plan.

The sizes, shapes, and levels of the sewers at the boundaries of the different districts were often very variable. Larger sewers were made to discharge into smaller ones; sewers with upright sides were connected with egg-shaped sewers; and egg-shaped

* Among this Committee were the Earl of Euston, Colonel Sir Frederick Trench, M.P., and General Sir Patrick Ross. Their report was published 23rd April 1836.

† Report published by Weale, 27th August 1851.

sewers with the narrow part uppermost were connected with similar sewers having the narrow part downwards. Indeed, so little care and design were observed in these matters, that even the governing bodies themselves appeared not to be in possession of any accurate information as to the dimensions or arrangement of the works actually existing under their control.

The evils of this system, as manifested in the defective drainage of the metropolis, were beginning to be seriously felt, and some of the Boards decided to take more active steps to improve matters. As an instance of this, it may be mentioned that the most important body out of the city, the Westminster Board of Sewers, adopted in 1844 the unwonted course of appointing an engineer (or surveyor, as he was then called) by a stringent competitive examination. Other bodies also exerted their powers, but the system generally was too defective to admit of much real improvement, and it was only by a radical change that this could be effected.

### The Consolidated Commission of Sewers, 1848 to 1855.

13. This change was brought about by the action of public opinion in 1848. The subject came forward in the parliamentary session of that year, and the result was the passing of an Act on the 4th September 1848 (11 & 12 Vict. cap. 112) "to consolidate the Metropolitan Commissions of Sewers."

14. This Act empowered Her Majesty to issue a Commission uniting the whole of the before mentioned authorities, with the important exception of that in the City, into one general Board under the above title, whose jurisdiction should extend to any "places or parts in the counties of Middlesex, Surrey, Essex, and Kent, or any of "them, not more than twelve miles distant in a straight line from St. Paul's Cathedral, "but not being within the city of London or the liberties thereof."

The Commission had power, not only to keep the sewers in order, but also to make new ones "necessary for effectually draining the area within the limits of the Commission:" but the powers did not point to any drainage measure, on a large scale, for removing the sewage from the neighbourhood of London.

It was, however, enacted that every house should be provided with a proper water-closet or privy, and should be drained into the main sewers; and the Commissioners were required to carry out these drainage provisions.

As a consequence of the general want of information, it was also enacted that they should cause to be made a complete survey and map of the metropolis within the limits of their jurisdiction, on which should be shown the levels, the particulars of all sewerage works, and such other indications as might be necessary for the purposes of the Act, or for the general advantage of the ratepayers. This was afterwards carried out with the co-operation of the Ordnance Office, resulting in the well known large-scale survey which has been of such great public use.

The area controlled by the Commissioners was divided into separate "Sewerage Districts," on each of which a rate could be levied for the expenditure incurred by the Commission.

15. The Royal Warrant issued under the authority of this Act appointed twelve Commissioners, to whom were added five ex-officio representatives from the City. They were unpaid, and the duration of their office was fixed at two years.

16. They began zealously on the improvement of the house drainage, the abolition of cesspools, and the introduction of pipe-sewer communications between the houses and the main drains; but they did not remain long in office, for in 1849 they were superseded by a second body, who took steps towards adopting measures of a more comprehensive character. The new Commission held that the sewage should be kept out of the Thames altogether, and instructed their consulting engineer, Mr. Austin, to prepare a plan for laying down lines of sewers converging into large tanks or "sumps," from which the sewage could be pumped up and conveyed away for agricultural purposes. A rival plan was however offered by the chief surveyor, Mr. Phillips, who strongly opposed this diversion of the sewage, and recommended an extension of the intercepting system for discharging it into the Thames below London.* Both these plans found strenuous supporters, and the Commissioners, being unable to agree to either, took the step of advertising for competitive plans for a complete systematic drainage of London.

* *See* printed Minutes of the Commissioners.

One hundred and sixteen designs were sent in, but the Commissioners were still unable to come to any decision upon them, and in the midst of the perplexity, and of the public excitement thereby produced, the Commission resigned.

17. The third Commission comprehended several gentlemen of eminent engineering ability, among whom were Sir John Burgoyne, Mr. Robert Stephenson, Mr. Rendel, Mr. (afterwards Sir) Samuel Morton Peto, Colonel Dawson, R.E., and Captain Vetch, R.E. This Commission began by classifying and arranging the competitive plans sent in to their predecessors. Some of these had much merit, particularly one by Messrs. Maclean and Stileman, which, adopting the interception principle, carried the outfalls to the sea, and made use of the sewage for reclaiming waste lands on the Essex coast. The Commissioners, however, eventually reported, on 8th March 1850,* that none of the plans could be recommended for execution, and they determined to appoint an engineer of their own selection to prepare a scheme for the main drainage of the metropolis, taking advantage of all the pre-accumulated information on the subject. The engineer selected was Mr. Frank Forster, who had long been one of the most able railway assistants of Mr. Robert Stephenson.

18. Mr. Forster, with the aid of two other officers of the Commission, Messrs. Grant and Cresy, first prepared designs for the drainage of the south side, and presented his Report thereon 1st August 1850.† Adopting the fundamental principle shadowed forth in former plans, he proposed to form one main intercepting sewer; but, owing to the physical configuration of this part of London, none of the water would flow away by gravitation. There was to be a pumping station on the banks of the Ravensbourne, to raise the water about 25 feet, and a second pumping station to raise the water from the continued sewer into a reservoir, in Woolwich marshes, which was to receive it during the intervals of the tides. The sewage was to be discharged into the river at the top of Woolwich Reach, eight miles below London Bridge.

Mr. Forster's Report on the northern drainage, in the preparation of which he was assisted by Mr. Haywood, the engineer of the City Commission of Sewers, bears date 30th January 1851. He proposed to intercept the whole of the existing drainage by means of two main conduits, the first at such a height as to allow of the discharge of the water by gravitation, and the second at a lower level to meet the outfalls of the lowest sewers. These intercepting lines were to converge to a point on the eastern bank of the River Lea, where a pumping station was to be erected, and the waters from the low level sewer were to be raised to the upper one. From thence the united sewers were to lead to a reservoir near Galleon's Reach, and the sewage was there to be discharged at such period of the tide as to prevent its reflux to London.

The positions of the main sewer outfalls proposed by Mr. Forster are shown by the letters F. on the plan, Appendix C.D.

Mr. Forster calculated his works to carry off a fall of rain equal to $\frac{1}{4}$ inch in 24 hours, in addition to the daily flow of sewage.

The total lengths of intercepting sewers to be made were, on the north side about 38 miles, and on the south side about 13 miles. The estimated cost was 1,500,000*l.*, excluding land and compensations.

19. The Commission had no power to raise the money to carry out these works, and was in its turn superseded; and a fourth Commission, appointed in 1852, renewed the consideration of the plans proposed by Mr. Forster; but Captain Vetch, R.E., a member of that Commission, propounded a different scheme of his own, which again raised a division among the Commissioners as to the relative merits of the plans before them. Mr. Frank Forster's health gave way under the anxieties of his position; he resigned his office, and shortly afterwards died.

20. The fourth Commission was superseded by a fifth, appointed late in 1852, who were met at the outset of their proceedings by a plan submitted to Parliament by a private company, under the title of the "Great London Drainage." The discussion of this scheme extended over a great part of the Session of 1853, and it was ultimately rejected by a committee of the House of Commons.

---

* The Report is inserted in the Min. Proc. Inst. C.E., Vol. xxiv., p. 513.
† Min. Proc. Inst. C.E., Vol. xxiv., p. 518.

Immediately after this, Mr. (now Sir Joseph) Bazalgette, who had been appointed engineer to the Commission, was instructed, in conjunction with Mr. Haywood, to prepare a scheme for the drainage of London, north of the Thames; these gentlemen took as a basis the proposals of Mr. Frank Forster, modifying and improving them, so as to meet the altered circumstances of the metropolis, and their plans were submitted to and approved by Mr. Robert Stephenson and Sir William Cubitt (the consulting engineers to the Commission) in the early part of 1854. The outlet selected by them, marked B.H. on the map, Appendix C.D., was in the same place as that proposed by Mr. Frank Forster for the north side.

21. Shortly before this time the subject of the metropolitan sewage had been taken up by a public body, who interested themselves in matters of a sanitary nature,—the General Board of Health. In several of their reports they had pointed out what they considered to be serious defects in the existing state of things, and in 1854 a plan was brought forward, under their auspices, for entirely remodelling the whole London drainage by introducing what was called the "separate system," *i.e.*, the system of separating the sewage from the rainfall, and providing independent channels for the removal of each.

This plan received the countenance of the then Secretary of State for the Home Department, who communicated his opinion to the Sewers Commissioners. This body, feeling that they could not agree with the Government on the point, informed the Home Secretary of their decision, and forthwith resigned.

A sixth Commission was appointed at the end of 1854, partly by the Government, and partly by election. They invited new plans, and considered several of them, but did not arrive at any solution of the question.

22. In the meantime the state of the River Thames within the Metropolis was becoming very alarming. As already stated, the first consolidated Commission, immediately after its appointment in 1848, had begun to take cognizance of the large extent to which cesspools existed in the middle of the populous districts. We have it in evidence that at that time these collections of pestiferous matter were some 200,000 in number, containing an aggregate capacity of about $5\frac{1}{4}$ millions of cubic feet. The Commissioners resolved to put their powers in force by doing away with them. Their abolition was gradually accomplished, the contents being pumped out and discharged into the Thames; watercloseets were compulsorily substituted, and house drains from them were connected to the main sewers, which then discharged into the Thames in the heart of London.

The effect of this wholesale change soon became manifest in the foul state of the river, the noxious smell of which was intensified by great deposits of sewage matter on the large flat banks, left dry at low water, close under some of the finest and most populous parts of the metropolis; and it was clear that this evil must continue to increase with the growth of the population.

But this was not all. The metropolis had suffered severely from the cholera visitations in 1831–2, 1848–9, and 1853–4, and strong suspicion prevailed that defective drainage had contributed to the alarming mortality.

23. It was perceived that, although the Consolidated Commission of Sewers was an improvement on the original divided jurisdiction, it was still inefficient to carry out the great work of purifying the river. This body had been charged with control over a large area, and with large powers of rating, but they had hitherto attempted only one large work, namely, a sewer in Victoria Street, which, after costing a large sum, had fallen into ruins. There were many anomalies and difficulties in regard to their jurisdiction, and they themselves recommended large changes. Under these circumstances the Government decided to create a new representative body; and a Bill to effect this object was accordingly brought in by Sir Benjamin Hall, the First Commissioner of Her Majesty's Works and Public Buildings, on 16th March, 1855. It was carefully discussed in both Houses, and it received the Royal Assent on the 16th August in that year.

### The Plans of the Metropolitan Board of Works, 1856.

24. The Act above mentioned, 18 & 19 Vict. cap. 120, was entitled "An Act for the better Local Management of the Metropolis."

The object was twofold; first, to create a number of local or District Boards of Works, each of which should generally control the public structural matters in its particular district, and should have entire charge of the local drainage, comprising all sewers except the more important ones, which were termed *main sewers*.

Secondly, to form a Corporate Board, to be called the *Metropolitan Board of Works*, elected by the ratepayers. The duties of this body were of a more general character. They had power to control the district boards, to regulate streets and buildings, and generally to superintend all great municipal works of construction. But their most important office was to take charge of the main sewers of the metropolis, and in particular to construct works for a comprehensive system of main drainage.

The chief portions of the Act referring to this latter provision were as follows:—

CXXXV. The sewers mentioned in Schedule D. to this Act, being the main sewers . . . . . , shall be vested in the Metropolitan Board of Works;

And such Board shall make such sewers and works as they may think necessary for preventing all or any part of the sewage within the metropolis from flowing or passing into the river Thames in or near the metropolis;

And shall cause such sewers and works to be completed on or before the 31st day of December 1860.

And the said Board shall cause the sewers vested in them to be constructed, covered, and kept, so as not to be a nuisance or injurious to health; . . .

And may cause the sewage and refuse from such sewers to be sold or disposed of as they may see fit, but so as not to create a nuisance. . . . .

CXXXVI. Before the Metropolitan Board of Works commence any sewers and works for preventing the sewage from passing into the Thames, as aforesaid, the plan of the intended sewers and works for the purpose aforesaid, together with an estimate of the cost of carrying the same into execution, shall be submitted by such Board to the Commissioners of Her Majesty's Works and Public Buildings; and no such plan shall be carried into effect until the same has been approved by such Commissioners.

Powers were given to both the Metropolitan and the District Boards to levy rates in order to provide for their expenditure, and to borrow money when necessary.

The Metropolitan Board were bound to send to Government an annual report of their proceedings, and a statement of their accounts, which were to be laid before Parliament.

25. The Metropolis Local Management Act came into operation in January 1856, and the Board, having appointed their officers, immediately proceeded to the consideration of the whole question of the main drainage of the metropolis, and instructed their chief engineer, Mr. Bazalgette, to report, at the earliest possible period, as to the works necessary for the accomplishment of the object. In accordance with these instructions, a plan was prepared, the main features of which were similar to that of 1854, but modified and improved.

26. In accordance with the proviso in the Act, the plan prepared by Mr. Bazalgette was submitted to Sir Benjamin Hall on the 3rd of June 1856.

At this point of the history the question arose as to the most appropriate *position of the outfalls* for the main sewers. In the plan presented by the Board the outfalls were shown at Barking Creek on the north side, and in the Plumstead marshes on the south side. The particular points are marked A. on the plan, Appendix C.D.

As Sir B. Hall had been previously given to understand that the position of the outlets was to be fixed by the Board in accordance with certain data obtained by them in 1851, he thought it desirable that some person should be appointed to test the accuracy of such data. Accordingly he communicated with the Admiralty, and requested them to name some person for the purpose, who was thoroughly conversant with the Thames. The Admiralty named Capt. Burstal, R.N. (who was shortly afterwards appointed Secretary of the Thames Conservancy Board), and he was directed to inquire into the matter.

Captain Burstal accordingly made a number of float experiments, to ascertain the extent of the tidal action in the Thames, and reported thereon to the First Commissioner in a letter dated 30th June 1856, a copy of which has been put in evidence by Captain Burstal before this Commission. (*Q.* 6491.)

Immediately on the receipt of this report, the First Commissioner wrote to the Metropolitan Board of Works a letter, dated 2nd July, concluding as follows: —

"By the Metropolis Act of 1855 it is provided that the Metropolitan Board of Works shall make sewers and works for preventing all or any part of the sewage within the metropolis from flowing or passing into the Thames in or near the metropolis. But the scheme submitted for the approval of the First Commissioner actually provides that the sewage shall flow into the Thames at a point within the metropolis. It consequently follows that, before any such scheme can be carried out, it will be necessary to call upon Parliament to

repeal so much of the Act of last session as provides for the purification of the River Thames within the metropolis. The First Commissioner feels he cannot undertake to do this, and, considering that the scheme is entirely at variance with the intentions of the Legislature as set forth in the Act which passed last August, he considers it to be his duty to return the plans which were submitted for his approval.

27. On the 5th of November 1856, a second plan was submitted, having outfalls two or three miles lower, namely, at the points marked B. on the map, Appendix C.D.

The Metropolitan Board gave to the First Commissioner an intimation that they had considered other plans for discharging the sewage into the river below Gravesend: but that, as such an extension would add between one and two millions sterling to the outlay, and as the increased expenditure would be incurred, not to benefit the inhabitants of the metropolis, but to meet the wishes of persons residing on the banks of the river, the Board had declined to entertain these schemes. Notwithstanding, if Her Majesty's Government deemed such a scheme desirable, the Board would readily undertake the work, the Government providing for such additional outlay out of the national revenue.

Sir Benjamin Hall on examining the plan, considered that, although the proposed points of outfall were just outside the metropolitan boundary, the sewage would flow back into the metropolitan area, and he returned that plan also. The two plans which the Board had submitted were, in fact, considered by him wholly at variance with the spirit and intent of the Act, and with the plain intention of the Legislature.

In the meantime, the First Commissioner, having reference to Captain Burstal's previous investigations on the motion of the tides, had desired him to specify the nearest points at which the sewage of the metropolis could be discharged without reflowing into the metropolitan area. In reply to this, Captain Burstal wrote the letter, dated 18th November 1856, which is printed in Appendix L.

He said,—

> I should therefore submit that the nearest point to London at which the [southern] outfall be made be in the upper part of Erith Reach, 15 miles from London Bridge, $\frac{1}{8}$ mile from Erith Church, and $\frac{1}{4}$ mile below Jenningtree Point, nearly opposite Rainham Creek.
>
> * * * * * * *
>
> For similar reasons, I would suggest that the outfall on the north side be at Rainham Creek.

These points were about $1\frac{1}{2}$ mile lower than those named in the last proposition of the Board, and they were afterwards known by the designation B*. They are shown with this mark on the plan, Appendix C.D.

28. The Metropolitan Board for the time adopted the recommendation, and sent to Sir B. Hall on the 22nd December a third plan, thus amended. The First Commissioner, however, determined to submit the whole subject of the metropolitan drainage to the consideration of independent professional advisers, and appointed as Referees for this purpose Captain Douglas Galton, R.E.; Mr. James Simpson, the Engineer of two of the London Water Companies; and Mr. Thomas E. Blackwell, Engineer of the Kennet and Avon Canal Navigation.

The reference to these gentlemen was made on the 31st December 1856, and as their inquiry bears materially on the questions before us, it will be useful to notice it in some detail.

### The Inquiry of the Government Referees, 1857.

29. The instructions of the First Commissioner requested the Referees to consider the plans submitted by the Metropolitan Board; but expressed his wish that they should not confine their attention merely thereto, but should give him the fullest information they could afford him, reporting generally their views on the question of the main drainage of the metropolis and the points of outfall. The following extract will show the manner in which the question presented itself to the Government at that time:—

> The plans now sent to you fix the outfalls at the points already indicated [in and near Erith Reach], but, inasmuch as it is desired, by the inhabitants of towns bordering upon the river below the 15 mile point, that the main sewer should be extended, and that the outfall should be placed at a greater distance from the metropolis, provided funds are obtained for the purpose of meeting the increased expenditure, the First Commissioner wishes you to report upon any such more distant points of discharge as may fairly meet the requirements alluded to.

The First Commissioner also directed the Referees to consider the subject of the most effectual means of utilising the sewage, "as a strong feeling seemed to be "entertained by members of the Metropolitan Board of Works, and others, that "the sewage of the metropolis might be made a source of profit."

He further directed them to obtain accurate information as to the amount of sewage discharged, as there had been great discrepancies in the statements made on this point at different times.

30. The Referees, having collected information from a great variety of sources, and having examined a large number of plans forwarded to them, reported to the First Commissioner on the 31st July 1857. The Report, which was very full and elaborate, was afterwards published, with a large mass of appended documents and plans, as a Parliamentary paper (3rd August 1857).

The Report was divided under four heads; viz.:—

1st. The principal features of the existing system of drainage in the metropolis; the system of drainage proposed by the Metropolitan Board of Works; and the amount of sewage for which provision should be made.

2nd. General consideration of the several schemes submitted for draining the metropolis.

3rd. The system of drainage which the Referees recommended, and the modifications in the plan of the Metropolitan Board of Works which this system would necessitate.

4th. The extent to which districts adjacent to London, which would be benefited by the proposed mode of disposing of the sewage, ought to contribute thereto.

The Report contained a large quantity of matter which, though important at the time, has, from the progress of events, now lost its interest; and attention may be confined here to such points as bear on the present inquiry.

31. The amount of sewage and rainfall for which the plan of the Metropolitan Board of Works provided was founded on a prospective population of 3,413,400 persons, with a discharge of sewage of 5 cubic feet per diem, to which was added a rainfall of $\frac{1}{4}$ of an inch per diem in the urban and $\frac{1}{8}$ of an inch in the suburban districts. This gave the following quantities* :—

| | Gallons per Diem. |
|---|---|
| Total sewage per diem | 106,623,000 |
| Rainfall, north side | 215,325,000 |
| Do. south side | 109,269,000 |
| Total maximum sewage and rainfall which the sewers were to be capable of removing | 431,217,000 |
| Or, in cubic feet per diem, about | 69,000,000 |

The Referees disagreed with this estimate, as their sewer gaugings gave higher results than those assumed by the Metropolitan Board of Works; and, after a somewhat elaborate statement of reasons, they recommended that 7 cubic feet of sewage should be estimated daily for each individual of an assumed population of about 3,578,000, and that provision should be made for an addition of rainfall (estimated at two-fifths of an inch during the eight hours of maximum flow), giving a total quantity of about 185,600,000 cubic feet per diem. To this they made a further addition for suburban areas, giving on the whole, in round numbers, 211,000,000 cubic feet per diem to be disposed of, or three times the quantity contemplated in the Board of Works plan. The Referees said, in reference to this plan—

We must express our decided opinion that this plan does not provide for the removal of a sufficient quantity of sewage from the population of the metropolitan districts, including the prospective increase, and that the provision for the removal of storm water during rain is not carried to the extent necessary to prevent the frequent pollution of the river.

32. With respect to the *position of the outfalls*, proposed by the Metropolitan Board, the remarks of the Referees may be inserted entire.

The outfall for the sewage of the north side is situated at the confluence of the Rainham Creek with the River Thames at a point which is designated as B* on the maps of the Metropolitan Board of Works; the outfall for the sewage of the southern side being placed at a spot opposite, on the south side of the river.

We have received from a committee of gentlemen who reside in the neighbourhood of Erith and Gravesend a statement of their objections to this outfall.

With respect to this locality we have to observe that, if a stream loaded with sediment be poured into a river, the sediment will have a tendency to deposit and to form shoals, unless the place at which the stream is turned into the river be subject to the action of a strong current. Erith Reach, at the head of which the outfall has been placed, is stated by Mr. Stephen W. Leach, the engineer of the Conservancy of the Thames, to be at the present time peculiarly liable to shoal; and we, therefore, consider that upon this ground alone it would be very injudicious to select this as the point of outfall.

* *See* Table in Referees' Report, page 13.

We have also carefully studied the very valuable series of float experiments made by the late Mr. Frank Forster, engineer to the Metropolitan Commissioners of Sewers, and those made by Captain Burstal, R.N., in the course of last autumn, as well as some float experiments made recently by Mr. Homfray, the engineer of the Erith and Gravesend Committee; and we have also made some experiments ourselves at this place. The conclusion at which we have arrived upon the subject is as follows; viz.:—

That a float put into the centre of the stream at high water will move down the river with the ebbing tide, and ascend again with the flowing tide, and that at the end of a fortnight it will be found to have reached a point in the river about five miles below that at which it was put in. But the part of the river selected for the outfall B* is full of shoals which cause eddies and slack water in these places, as is shown by the frequent tendency of the floats to set inshore; and consequently the sewage would be liable to form deposits of mud upon the banks, of the same putrescible character as is found in the Thames in London at the present time.

It must also be recollected that, whilst the floats, when once put in, were followed up and down the river in the strength of the stream, the sewage would be turned in continually twice every day; and that much of that portion of it which would flow into the river during the ebb tide would hang about in slack water, and be liable to be carried up with the flood to a point much above that which is assigned as the probable limit by float experiments made in the fairway of the channel. It is worthy of remark that the water is sometimes salt in the river as high as Barking Creek and Woolwich.

Also, it cannot be denied that sewage turned into the river in two concentrated streams above Erith would be much more objectionable to the inhabitants of that locality than the same sewage flowing into the river by a number of separate channels at points several miles higher up.

With the view of avoiding the objections, that have been urged by the inhabitants of Erith against the outfall at B*, Mr. Bazalgette has proposed to bring the southern sewage across the river, and to convey the united stream to Mucking Flats. Although we concur with Mr. Bazalgette in thinking it expedient to seek for an outfall in that locality, we are of opinion that the particular point which he has selected is objectionable, because it is situated in a part of the river subject to slack water during a great portion of the ebbing tide.

The Referees summed this up in their conclusions, as follows:—

That the proposed outfall at B* in Erith Reach is objectionable because it would not effectually prevent the sewage from returning within the limits of the metropolitan boundary; because it would have a deleterious effect on the health of the district; and because it would probably be prejudicial to the navigation.

33. In Section III. of their Report the Referees explained a plan which they, considering all the circumstances, had prepared and recommended for adoption.

They considered that the system of interception as first laid down by Mr. Frank Forster, and subsequently followed up by Mr. Bazalgette, must form the basis of any sufficient scheme; and they therefore adhered to the general plan of intercepting from a higher level, and of pumping from such levels as were too low for a gravitating discharge. But they differed somewhat from these authorities as to the detailed mode in which these principles should be carried out.

34. In regard, however, to the discharge of the sewage, they proposed a most important modification, namely, to remove the outfalls to a point much lower down the river.

On this point their remarks were as follows:—

After a careful consideration of this question in all its bearings, we are of opinion that the best mode of disposing of the sewage of the metropolis is to place it where it will be rapidly and certainly mixed with large volumes of water, and be finally carried into the sea. We consider that the most effectual method of securing this object is to place the outfall at some point in a deep tidal river where the range of the tide is considerable, where the set of the stream is strongest against the shore, and where its outward flow is assisted by the fresh water from a large drainage area.

There are two points on the River Thames which entirely fulfil these necessary conditions, viz., one on the north side very near to the Mucking Lighthouse, in Sea Reach; and the other on the south side, at Higham Creek, in the Lower Hope. At both of these places the water near the shore is very deep, and the ebb-tide very strong.

We consequently made some tidal experiments at these places with the assistance of Captain Burstal, R.N.; and we also received, from the committee of gentlemen from Erith and Gravesend, the results of a valuable series of tidal experiments made by Messrs. Homfray, their engineers, at the same place.

And we also consulted Captain Bullock, R.N., upon the subject, who, by his valuable surveys, is thoroughly acquainted with the River Thames.

The results of these experiments are, briefly, as follows:—At both places the currents are very strong in the ebb-tide, and a considerable period of slack water occurs during the flood; and, unlike the upper parts of the river, where the tide is concentrated into one stream, the great expansion in the breadth of the river at Sea Reach causes great variations in the set of the currents at different parts; thus, while the ebb-tide sets upon the northern shore of Sea Reach, the flood-tide sets upon the southern shore. This was shown by the fact that floats which entered Sea Reach with the ebb-tide set in towards the northern shore, and were not carried up the river again with the following flood-tide, whilst a large volume of fresh sea water from the Nore comes up along the south shore at every tide. The strength of the current at both the above-mentioned places is sufficiently great to prevent any deposit of materials brought down by the sewers from taking place in the bed of the stream; and the great expanse of water, the continual accession of clean water, and the rapidity of current, would ensure the mixing of the sewage with water under the most favourable circumstances, and at a point in the river where the shores are almost uninhabited.

These are the only places in the river, either above or below, which appear to us entirely to fulfil the conditions essential to the object in view; and we have, therefore, selected them as the points of outfall for the metropolitan sewage.

The points of outfall proposed by the Referees are shown in the sketch map, Appendix C.F.

35. The Referees proposed that the sewage should be carried to these points of outfall by a main channel on each side of the river, delivering at low water.

That on the north side would, reckoning from the boundary of the Metropolitan area, be about 20 miles long; and that on the south side about $16\frac{1}{2}$ miles long.

The north channel was to be 39 feet broad and $16\frac{1}{2}$ feet deep; the south channel 37 feet broad and 16 feet deep. The fall was to be six inches per mile, which it was calculated would give a velocity of $2\frac{1}{2}$ feet per second, sufficient to keep them clear of deposit.

But, in order to ensure this velocity at all times, it was proposed, during dry weather, to admit tidal water from the Thames to the head of the channels by means of reservoirs formed to equalise the flow.

36. The Referees considered that the great extent to which the sewage would be diluted, after the outfall channels were fed with the tidal water at their heads, would render them comparatively innoxious streams. It was not, therefore, in the first instance, proposed to cover them, except where they passed populous neighbourhoods, or where they were formed by tunnelling under raised ground.

The Referees were of opinion that it would be necessary to provide storm overflows for certain sewers near the point of interception to convey the water directly into the river, and to discharge at all times of tide.

37. They estimated the cost of the works they recommended as follows:—

| | £ |
|---|---|
| Intercepting and collecting main sewers, and their connexion with the main outfall channels - - - | 3,080,465 |
| Main tidal outfall channels - - - - | 2,356,800 |
| | £5,437,265 |

exclusive of charges for superintendence, &c., assumed at 4 per cent.

38. The Referees devoted much attention to the subject of the possible utilization or deodorization of the sewage, and it may suffice here to give their general conclusion on the facts then before them:—

That, under these circumstances, and having regard to the inexpediency of making the question of the effectual drainage of the metropolis dependent on commercial considerations, the only practicable mode of disposing of the sewage of the metropolis is to provide for its rapid removal from inhabited districts, and for its collection in main outfall channels, where private enterprise, under proper control, may be at liberty to utilize it; but that, when not required for purposes of utilization, these channels should provide for its flow in the most expeditious manner into the sea.

39. The Referees concluded as follows:—

In conclusion, we would impress upon you our decided conviction that, if the Thames is to be completely purified, no plan less comprehensive than the one which we have suggested will effect this object.

The estimated expense of this plan is considerable; and some improvement upon the existing state of things might possibly be obtained for a smaller outlay; but a diminution in the dimensions of the sewers does not proportionately diminish the cost of their construction; and, moreover, the increase of population, which is so rapidly taking place in every direction round the metropolis, would necessitate the extension of any less comprehensive plan than the one which we have suggested, at no very distant period.

40. The Appendix to the Referees' Report contained a great mass of information, among which may be specified:—

Elaborate chemical investigations by Messrs. Hofmann and De Witt, and Mr. Etheridge.

Tables of population, rainfall, percolation, &c.

Experiments on the effect of running water in moving solid substances.

Data by Captain Bullock, R.N., Captain Burstal, R.N., Mr. Leach, Mr. Frank Forster, and Mr. Homfray, as to the River Thames, and the tidal movements therein.

Protests and evidence against the proposed measures of the Metropolitan Board of Works, by parties interested in the lower part of the river.

## Discussions of the Subject, 1857–8.

41. The report of the Referees was submitted to the Metropolitan Board, who, in October 1857, wrote to Her Majesty's Office of Works a letter objecting to the proposed scheme on several grounds, the most important of which were the proposed locality and mode of discharge into the Thames, and the long outfall sewers leading thereto. They urged that the proposed open sewers would be a greater nuisance than the river, by reason of the less dilution of the sewage; and that the plan of discharging only at low water would neutralize a considerable part of the advantage proposed to be gained by going 15 miles lower down.

The Board also objected to the proposed enlargement of the area to be drained, and to the increase in the dilution of the sewage, as requiring larger dimensions of the sewers.

On the 5th November 1857 a conference was held between the various parties at the Office of the First Commissioner, and the questions at issue were fully discussed. The Chairman of the Metropolitan Board inquired whether Her Majesty's Government would be prepared to contribute the additional cost of executing the work if the Board should decide upon carrying the outfalls to Sea Reach. The First Commissioner stated that, in his opinion, Parliament would refuse to make any contribution to the works in question.

The Referees then wrote a letter to Sir Benjamin Hall, dated 12th November 1857. In regard to the points of discharge and the long outfall sewers they gave lengthy explanations. They said that the question of their being open or closed did not affect their efficiency, and they pointed out that they might be covered if thought desirable. They also defended the proposed mode of discharge, and added:

> But we have not selected the points of outfall named in our Report solely on account of their distance from the metropolis.
>
> Our objections to the outfall at B* in Erith Reach were mainly founded upon the fact that this reach is very liable to shoal, and that therefore the sewage when discharged there would hang about in the eddies and slack water, and, besides having a tendency to move up the stream with the next tide, would subside on the shores and form deposits of mud. These deposits would not only interfere with the navigation, but would, from their putrescible character, be very injurious to the adjacent inhabited districts.
>
> We selected Higham Creek and Mucking Lighthouse as the points of outfall, because, after a careful examination of the whole river, we considered, and do still consider, that these places fulfil the conditions essential to the discharge of the metropolitan sewage without injury to the river.

With regard to the proposed greater dilution of the sewage, the Referees reiterated their arguments, and added:

> We can only repeat that, if it be desired to preserve the River Thames from pollution within the metropolitan districts, that object will not be effected to a reasonable extent if the provision for rainfall be reduced below what we have recommended; and we are firmly convinced, from the considerations into which we have already fully entered, that the sewers proposed by the Metropolitan Board of Works would too frequently overflow into the river in London, and more frequently at the storm overflows into the rivers Lea, Roding, and Ravensbourne.
>
> The plan of the Metropolitan Board of Works would, as we have explained, permit a very frequent flow of sewage into the Thames during rain, at a time when the sewage would be highly charged with deleterious matter.

About this time resolutions were forwarded to the Metropolitan Board of Works from the principal Vestries and District Boards of the metropolis, urging them to withhold their assent from any scheme which should impose upon the ratepayers of the metropolis the burthen of carrying the sewage beyond those points which would satisfy the strict requirements of the statute; and on the 16th November the Board passed a resolution to the effect that to extend the points of outfall to Sea Reach at the cost of the metropolitan ratepayers would be unjust to them, and a contravention of the principle of the Metropolis Local Management Act.

42. On the 23rd November 1857 the Metropolitan Board resolved:

> That the reports of the Board on the main intercepting drainage of the metropolis, submitted to the Commissioners of Her Majesty's Works and Public Buildings, also the reports of Messrs. Galton, Simpson, and Blackwell, upon the same subject, be referred to the engineer of the Board, together with two other civil engineers, with instructions that they report to this Board as to the best means of carrying out the main drainage of the metropolis; and, in reporting on the expenses of the works which may be proposed, they will state, first, the amount necessary for carrying the sewage of the metropolis to B*, and, secondly, in case funds should be provided, the further cost of carrying the sewage to points of outfall in Sea Reach.
>
> That Thomas Hawksley, Esq., and G. P. Bidder, Esq., be the engineers associated with Mr. Bazalgette for the purpose stated in the foregoing resolution.

After some further correspondence, in the course of which the Government Referees gave additional explanations respecting the construction and mode of action of their

proposed outfall sewers, Mr. Bazalgette and his coadjutors proceeded to consider the subject, and reported fully thereon to the Metropolitan Board of Works on the 6th of April 1858.

As their Report virtually settled the system which was ultimately carried out, and into the working of which the present inquiry is directed, it is desirable to state its reasonings and conclusions somewhat fully.

### The Report of Messrs. Bidder, Hawksley, and Bazalgette, 1858.

43. The Report was divided under ten heads, viz.:

I. and II. Preliminary and historical.
III. Examination of the Report of the Government Referees.
IV. General observations upon the sewage and rainfall.
V. Area to be drained.
VI. Condition of the river.
VII. Internal drainage.
VIII. Outfalls proposed by the writers.
IX. Expense of other outfalls.
X. Conclusions.

44. Passing over the first two heads, the *Examination of the Referees' Report* was directed chiefly to the outfall sewers and the proposed reservoirs for feeding them with dilution water.

The writers said:

> One of the principal objects of the Referees has been the attainment of outfalls at a considerable distance from the metropolis. No practical engineer acquainted with the valley of the Thames can fail to see the difficulties which are involved in this project. The construction of outfall works for the drainage of a *low* district by *gravitation* to a *remote* point, when the only obtainable fall is a portion of the difference of level between high and low water marks, is only possible at an enormous sacrifice of time and money; nor would the matter be ultimately much improved in its pecuniary results if the aid of machinery were wholly or in part resorted to. The small declivity of the channel incident to great length also necessitates large dimensions, and these again involve a proportionately large outlay. Excessive cost is indeed an inseparable and wholly unavoidable incident of all such structural operations.
>
> The several plans of the Referees amply demonstrate that they have encountered all these difficulties, together with others peculiar to the case, created by themselves. Having determined to recommend points of discharge below Gravesend no less than 23 miles from the head of their outfall sewers on either side the Thames, it became necessary, in order to carry out the principle of drainage by gravitation, aided by dilution, to make large portions of these channels of more than EIGHT times what would have been the required capacity, upon any reasonable calculation, for the drainage of an enlarged metropolitan area extending to Hanwell and Richmond, as they estimated such area would be populated 40 years hence.
>
> The stream of water adequate to give to these sewers the hydraulic depth requisite to insure a sufficient velocity to keep them in a working state is only provided by nature on a very few days in the year, and frequently not for several successive months. The Referees were consequently forced to impose upon themselves the additional difficulty of suggesting reservoirs at the head of each of their outfall sewers in order to supply the deficiencies in the rainfall, and to provide the water necessary to secure the requisite velocity. These reservoirs, as we shall hereafter show, involve not only additional complexities and difficulties, but, even if practicable, they would entail such enormously enhanced first outlay and subsequent annual cost as to render the project extremely objectionable, if not wholly abortive.

They then went into a detailed examination of the Referees' plans; and the following extracts may suffice to show their opinion:

> Without saying that these works are absolutely impracticable, *i.e.*, that money, time, and skill, may not surmount the difficulties incident to them,—yet their execution must be attended with the utmost uncertainty, both of time and cost.
>
> * * * * * * *
>
> From the foregoing description it is obvious that the works proposed on both sides the river, even by the modified scheme of the Referees, are of a magnitude and character wholly unexampled.
>
> * * * * * * *
>
> Looking to all the foregoing considerations; to the enormous and uncertain cost necessarily attending the execution of such works; to the destruction of property they would involve; to the great annoyances and inconveniences that would be occasioned to the population on the lines of the sewers, both during and after their construction, and to the large annual cost of clearing them from deposit, we feel that an overwhelming case of necessity must be established to justify the adoption of a proposal of this description.

45. *The General Observations upon the Sewage and Rainfall* were largely occupied by a controversy as to the gaugings.

Messrs. Bidder, Hawksley, and Bazalgette objected to the large quantities which the Referees had provided for passing off, which they considered prodigious and astounding, and altogether unnecessary. They still maintained that, according to Mr. Bazalgette's plans, the quantity of rain water proposed to be removed would occasion storm overflows into the Thames upon only a very few days in the year.

In regard to the *Area to be drained*, the engineers objected to the extension proposed by the Government Referees, as one which was not only unnecessary, but would, if attempted, result in difficulties of an engineering and monetary character of the most formidable kind.

In regard to the *Condition of the River*, the engineers expressed their conviction that the influence of the sewage on the physical and hygienic condition of the Thames had been much mistaken, and greatly exaggerated.

They considered that the tidal scour, the land floods, and the agitation by steam-boats, were more influential contributors to the existing appearance of the river than the sewage; and that the disgusting effluvia, so much complained of, arose from deposits on filthy mud banks, rather than from the water.

On this account they recommended the embankment of the river in conjunction with the diversion of the sewage.

The chapter on *Internal Drainage* has but little to do with the present object.

46. The eighth chapter, on *The Outfalls proposed* by Messrs. Bidder, Hawksley, and Bazalgette, is so important in regard to the present inquiry that a large portion of it should be quoted here:

In discussing "the condition of the river," we have prepared the Board to anticipate that we have come to a clear and decided opinion that the remote outfalls proposed by the Referees are unnecessary for effecting the objects of the 135th section of the Metropolis Local Management Act. Our own experience had informed us, not only that it is extremely undesirable, in a sanitary point of view, to cause sewage matter to become intermixed with sea-water, and especially under circumstances which will occasion it to be brought up the river by the flood tide, but that, if the sewage matter were poured into a much larger volume of fresh or freshened water, in a flowing stream, it would become immediately oxygenized, and cease to exist as a noisome and offensive agent. The experiments of Dr. Letheby and Dr. Odling have fully confirmed our views.

We have, therefore, unhesitatingly selected for recommendation, as points of outfall, places situated in approachable situations, as near as possible to the metropolitan boundary, and as far as possible from human habitations. Barking Creek on the north side, and Crossness Point on the south side, fulfil all the favourable conditions that are attainable on either side of the river. Both are situated in low and dreary marshes, where neither the works nor the sewage can give reasonable cause of offence to any one. Barking Creek is about 2 miles from Woolwich, and about 4½ miles from Erith. Crossness Point is midway between the two places, and about 3¼ miles from each. The mean sectional area of the river at these places is *four times as great as at London Bridge*, and the average volume of tidal water, *about* 400 *times as much as the volume of the sewage water to be admitted into it.*

The river is fresh, or nearly so, at low water and only moderately mixed with salts of marine origin at high water; more so, it is true, than we could wish; but much less so than at any point lower down the river.

These now suggested points of outfall contrast favourably with the outfalls which have recently been much under discussion and are popularly known as B* (B star). The B* outfall on the north is situated at the mouth of Rainham Creek, and on the south at a point of the river about a mile above the town of Erith. These points of outfall were, as we understand, recommended to the First Commissioner of Works by Captain Burstal, R.N., whose conclusions, as stated in a letter to the Right Hon. Sir Benjamin Hall, under date 18th November 1856, were arrived at from observations made on the river with floats. Upon these conclusions the First Commissioner suggested to the Metropolitan Board the points of outfall recommended to him by Captain Burstal; and the Metropolitan Board, desiring, as before mentioned, to meet the views of the Government, adopted the points so recommended. Appended to another communication from Captain Burstal to the Government Referees, dated 10th July 1857, is a note referring to diagrams showing the results of the experiments with floats. With respect to reasoning upon these diagrams, it may firstly be observed that any views that are not based upon a knowledge of the deodorising effects of air and water upon sewage must necessarily be empirical. But it is not needful at present to consider this part of the question, for the fact is that the diagram embodies, as it appears in the Referees' *Report*, an error which is fatal, not only to the diagram, but to any theory the Referees may have built upon it. * * * We exhibit in the Appendix to this Report a diagram which exemplifies, in colours, the extent of the errors induced.

With respect to the outfalls at B*, it should also be observed that those points are 3½ miles below the metropolitan boundary on the north side, and 2½ miles on the south. The additional cost which such extensions would involve would amount to not less than three hundred and fifty thousand pounds, exclusive of any increased pumping power and reservoirs they might render necessary. Beyond expressing an opinion that the sewage water may be delivered at B* under such circumstances as will render it inappreciable at Erith to every ordinary sense, as well as to the most elaborate chemical inquiry, we have little to observe with respect to these points of outfall. They will undoubtedly answer the proposed purpose, but certainly not so well, either in a sanitary or in a pecuniary view, as points situated higher up the river.

There is, however, this special reason to be urged against placing the outfalls below the metropolitan boundary, to which it may be useful to advert. Mr. Bazalgette, in one of his communications to your Board, has already shown that for many miles there are no points below the metropolitan boundary so remote from habitation and population, and, therefore, so well fitted for points of outfall, as the points close to the boundaries of the metropolis itself. At these points the banks of the river for several miles are low, marshy, and uninhabited; but beyond these points towns and villages on the river side become more frequent. Thus, whilst—

| | |
|---|---|
| The distance from Woolwich to Erith is | 6 miles |
| From Erith to Purfleet it is only | 2 „ |
| „ Purfleet to Greenhithe | 3 „ |
| „ Greenhithe to Grays Thurrock | 2 „ |
| „ Grays Thurrock to Northfleet | 1½ „ |
| „ Northfleet to Gravesend | 1½ „ |

So that, if it were desired to avoid the proximity of an outfall to population, otherwise than by going to an extreme distance, the best points at which to place them are, not at B*, where they would be near to Erith, but at points higher up the river, and nearer to the metropolitan boundary, where they would be about midway between Woolwich and Erith, and at least three miles from both.

Apart from the chemical, economical, and sanitary grounds on which we prefer outfalls situated at the points mentioned, we may pertinently observe that many difficulties will be encountered by attempting to obtain a more remote outfall. The necessary declivity of the sewer will soon bring it to a level at which it cannot empty itself *at any period of the tide.*

This is a very serious consideration, whether in regard to the making or repairing the channel, or in regard to cleansing it from the deposits brought down by the flood waters. Moreover, a sewer so constructed will either drain all the adjacent wells of their spring water or feed them with sewage water, according as the water naturally stands in the wells above or below the water in the sewer. At Gravesend, for example, either of these results would prove a serious evil. Unless also a large sum were expended in making the sewer of great diameter, and in providing a correspondingly increased flow of water through it, the necessary inclination would bring the outfall to so low a level as to necessitate the aid of much pumping machinery.

We are, indeed, of opinion that, if the local circumstances favoured such an arrangement, it would be preferable to place the outfalls within the metropolitan boundary rather than without it, especially on the south side of the river, where a very eligible situation presents itself in the Greenwich marshes, not far from the terminus of the river branch of the North Kent Railway. We believe this point is sufficiently far down the Thames to effect all sanitary objects connected with the river, and we are quite sure that, if the sewage water were discharged below low water mark, and at a suitable period of the tide, its presence would not be observed in the river, either at Woolwich or below. If this arrangement could be effected, a large expenditure, otherwise to be incurred in carrying the outfall sewer through the centre of the town of Woolwich, and to a point five miles lower down the river than the Greenwich marshes, would be saved. The terms of the Metropolis Local Management Act appear, however, to preclude the possibility of effecting such an arrangement.

Assuming, then, that the points we have indicated will find favour with the Board and receive the approval of the First Commissioner of Public Works, it remains only to describe the arrangements which we advise to be adopted for effecting the discharge of the sewage, not merely under the most favourable conditions, but under such circumstances as ought, in our opinion, to preclude the possibility of reasonable objection by other parties locally interested. We are convinced that the sewage might, in regard to health, be safely emitted at all periods of the tide; but, as in this case, some part of it would be washed up the river with the flowing tide, though certainly in an oxygenized, and, therefore, innocuous condition, we propose to construct reservoirs into which the sewage should be received for the purpose of being sent down the river during the first two and a half hours of the ebb tide. We propose, also, that these reservoirs shall be arched and turfed over, so as neither to permit the escape of effluvia, nor present an unsightly appearance.

On the north side the quantity of sewage to be received will amount to about 14,000 cubic feet per minute for six hours of the day, and to about 4,700 feet per minute, on the average, of the remaining 18 hours. The area of the reservoir should be about 12 acres.

On the south side, for the like periods, the respective quantities of sewage will be about 8,000 feet and 2,700 feet, and the area of the reservoir about seven acres.

On the north side the low level sewage will be raised at Abbey Mills by mechanical power to a height of about 34 feet, and will thence flow, by gravitation, into the reservoir; and on the south side the whole of the sewage will be similarly raised into the reservoir near the outfall from a depth of 25 feet.

It is also proposed that in both cases the sewage should be discharged into the river through submerged pipes, terminating below low-water mark.

The reservoirs are proposed to be constructed so as to enable the precipitation of the sewage matter to be effected by the application of lime. We have twice visited Leicester to see the process in operation, and have examined the state of the water, both immediately on quitting the works and after admixture with about twice its own volume of other water in the river. We can speak positively to the fact that the process is most successful; the water is completely deodorized, as well as rendered bright and tasteless. It does not subsequently become putrescent, although diluted with only twice its bulk of other water; both fish and vegetation have returned to the river within a short distance of the works, and the workmen at the water mills on the stream have recovered their health, which had previously been seriously affected by the foul condition of the river, and now state they have nothing to complain of, even in the hottest months of the year.

We do not, however, believe this process to be needed for the prevention of injury to the Thames, or to the health of the population residing on its banks; and we certainly do not recommend it for adoption, because, when produced in large quantities, the precipitated matter is unsaleable, and must be removed at considerable expense.

An objection has been made that the admission of sewage water into the river will be liable to create shoals in the navigable channel. It is scarcely worth while to argue this point, because the sewage matter emitted from the large sewers in London does *not* produce shoals, nor, in fact, can it, especially when, as in the case before us, the detritus of the roads will be detained, and removed, before the water is allowed to pass into the reservoir, and because sewage deposit, being nearly of the same specific gravity as water, is most easily moved by water, and is, moreover, always undergoing the process of destructive decomposition. We have, therefore, no hesitation in stating our decided conviction that shoals will not be created by the admission of sewage water into the Thames in the manner proposed.

47. The estimate of the cost of the works, according to the plan recommended, was stated at 2,300,000*l.*; and under the ninth head, the engineers estimated the further cost of carrying the sewage of the metropolis beyond the points recommended by them, at the following amounts, namely—

| | £ |
|---|---|
| To the points called B* - - - - - - - | 350,000 |
| To the points of outfall midway in Sea Reach - - - | 2,950,000 |

48. The *Conclusions* may be given verbatim:

First. As to the condition of the river:

That the causes of the apparent impurity of the river have been greatly exaggerated and much misunderstood; we find—

1. That the mechanical discoloration of the water is not due to the presence of sewage matter, but chiefly to the presence of inorganic substances brought down by land floods, or washed up and kept in motion by the tide.
2. That the chemical condition of the flowing water is not sensibly altered by the admission of sewage, because the organic matters become rapidly decomposed and disinfected by the action of the oxygen contained in the water through which they are diffused.
3. That mud containing much organic matter, derived in great measure from the sewage discharged above low-water mark, is deposited on the foreshores of the river and there putrifies.
4. That the condition of the flowing water of the river is not injurious to health, but—
5. That the condition of the stagnant mud is injurious to health.
6. That the offensive matters deposited with the inorganic mud are principally derived from the metropolitan sewers, and not, to an appreciable extent, from any more distant sources.
7. That the discharge into the river of comparatively small quantities of sewage matter from areas difficult to drain to any common outfall may be continued by outlets extended to low water without any sensible injury to the appearance of the river or its banks, or any detriment to the health of the inhabitants of the metropolis.
8. That the proper remedies for the evils arising from the present state of the river are two:
   1st. The interception of the greater part of the sewage of the metropolis above the present outlets, and its removal to, and discharge at, parts of the river below London, where its presence will be harmless;
   2nd. The construction of terrace embankments on both sides of the Thames to confine the tidal channel, accelerate the velocity of the stream, and prevent the exposure of the bed and banks of the river.

Secondly. As to the Scheme submitted by the Government Referees:

That the plan recommended by the Referees is needlessly large, excessively costly, and, as a work of construction, all but impracticable; we consider it especially objectionable in the following particulars:—

1. Because the amount of rainflow proposed to be carried off (two-fifths of an inch in eight hours, or six-fifths of an inch in 24 hours) is much greater than is requisite for the *reasonable* purification of the river.
2. Because the internal sewers necessary for the reception of the above amount of rainflow would be extremely difficult to construct under the streets and buildings of the metropolis, and would entail much loss and inconvenience to the inhabitants.
3. Because, although the peculiar arrangements of the Referees have been professedly made with a view to insure the dilution of the sewage to the extent of six times its maximum flow, yet that many of the most populous parts of the metropolis, in which the largest amount of dilution is necessary, are proposed to be provided for to only a much smaller extent.
4. Because, with the object of increasing the extent of the gravitating area, the Referees have adopted lower levels and smaller inclinations than are in practice found to be advantageous.
5. Because no means are suggested for obtaining the stated amount of dilution *within* the metropolis (but only *without* the metropolis), although rainfalls of the amount necessary for cleansing the enlarged sewers will occur only at distant intervals.
6. Because the outfall channels are of enormous size, and would be extremely difficult and expensive to construct in the stated situations and at the stated levels.
7. Because the outfall channels commence at five and four feet respectively below *low-water* mark, and discharge at 17 and 16 feet respectively below *low-water* mark, and consequently cannot be drained off.
8. Because these drowned channels and their open outfalls will accumulate deposits which it will be extremely difficult, and very expensive, to remove.
9. Because the water to be applied for dilution of the outfall channels will re-act on the internal drainage, and pen it back to its own level.
10. Because the cost of the proposed works will, upon any one of the three plans, very greatly exceed the amount at which they are estimated by the Referees, the probable cost of the smallest project being upwards of 9,000,000*l.*

Thirdly. As to the Scheme of the Metropolitan Board:

That the plan already adopted by the Board, with the modifications hereafter mentioned, is adequate to the satisfactory drainage of the metropolis and the reasonable purification of the river and its banks, and is also capable of effecting the following improvements, and of affording the following facilities:—

1. The removal of the maximum sewage water of 3½ millions of people.
2. The removal, in six hours of maximum sewage flow, of a rainflow equivalent to one-fourth of an inch per diem (produced by a rainfall of four-tenths of an inch per diem) from the area to become hereafter occupied by the above amount of population.
3. The relief of the low-lying districts from the effects of ordinary floods and tide-locking.
4. The delivery of the sewage and rainflow at points on the river where they will not be injurious to the health of the inhabitants of London, or of the population residing on the banks of the Thames, or be prejudicial to navigation.
5. The substitution of covered sewers for several of the existing open sewers.
6. The construction of the works at a reasonable cost (2,300,000*l.*) and in a reasonable period of time (5 years).
7. Facilities for treating the sewage with lime or other chemical agents with a view to its defecation before admission into the river, or to the realisation of its fertilising contents, if such should hereafter become commercially valuable.
8. Facilities for discharging the sewage at any (the most desirable) period of the tide, and for securing its transmission in an innocuous condition to the sea.

Fourthly. The modifications we recommend for more perfectly effecting the foregoing and other objects are chiefly the following:—

1. That the northern outfall channel shall discharge at Barking Creek in preference to any lower part of the river.
2. That the southern outfall channel shall, for the purpose of more completely complying with the intentions of the Metropolis Local Management Act, and without, at the same time, giving just cause of offence to the inhabitants of Woolwich and Erith, discharge into the river near Crossness Point; although, in our opinion, a situation equally eligible in every practical point of view presents itself in Greenwich Marshes, near the terminus of the branch line of the North Kent Railway.
3. That covered reservoirs of moderate size be formed near each outlet for the reception of the sewage water until it shall be discharged during the first hours of the descending tide, or to enable it to be defecated by lime or other chemical agent.
4. That the northern outfall sewer be constructed in brickwork rather than in iron, as designed by your engineer, and that a carriage road of 40 feet in width be formed over it.
5. That the dimensions of the southern outfall sewer be somewhat increased in size for the purpose of adding about 4,000 feet per minute to its capability of discharge.
6. That the outfalls of the few outlying sewers which cannot be reasonably brought within the major scheme be advanced into the river, so as to discharge below low-water mark.

49. In an Appendix the engineers added the following remarks:

*Deodorization.*—We have ascertained from the facts collected by us at Leicester and elsewhere that the cost of precipitation by means of lime amounts to 500*l.* per annum in respect of each million of gallons daily operated upon, and that the resulting product is commercially valueless. The sewage due to the present population of the metropolis, including some rainflow, amounts to about 80,000,000 gallons per diem. The cost of the application of the lime process to this quantity of sewage would therefore be 40,000*l.* per annum; but, as in the case of the metropolis there is clearly no advantage, practical or theoretical to be attained by the use of this process during the six colder months of the year, we estimate the extreme cost at only 20,000*l.* per annum. If, however, the sewage be discharged, at Barking Reach and Crossness Point, into deep water, and with the earlier portion of the descending tide, we believe the process will not be needed during even the hotter months, except, perhaps, under very occasional and very exceptional conditions of the river.

*Utilization of Liquid Sewage.*—We have been compelled to consider this question in connexion with the Referees' Report, and, being personally acquainted with most of the practical applications of town liquid, as at Edinburgh, Mansfield, Rugby, Croydon, and other places, come to the following conclusions:—

Firstly. That the fertilizing properties of the organic matters contained in town refuse are for the most part destroyed by the long continued action of water.

Secondly. That the cost and difficulties attending the application of liquid sewage in large quantities are absolutely prohibitory of its use.

Thirdly. That liquid sewage cannot in general be used with advantage in this climate, except in particular states of the weather, and in certain stages of the growth of the crops to which it is applied.

Fourthly. That commonly the distribution of liquid sewage is accompanied by a noisome odour, and, except in the case of its application to sandy or rocky soils of considerable inclination, is liable to induce the worst forms of marsh malaria.

Fifthly. That the proper distribution of the liquid sewage of the metropolis would require an area larger than that of the whole county of Rutland.

The Report was accompanied by several illustrative documents, the most important of which for the present purpose is a "Report of Henry Letheby, Esq., M.B., F.L.S., &c., on chemical and sanitary inquiries into the matter of the main drainage of the metropolis," dated March 15th, 1858. Dr. Letheby summed up his results as follows:—

The conclusions, therefore, at which I have arrived after a careful consideration of all the facts which I have been able to collect in respect of this subject are—

1st. That the turbidity of the river is not caused by the sewage which flows into it, but by the disturbance of the mud upon its banks, for within certain limits, the farther we go down the river, and away from the influence of the sewage, the greater is the turbidity.

2d. That there is no satisfactory evidence to prove that the *soluble* organic matters of the London sewage, when discharged into the Thames, do any serious injury to the river, or to the public health; for, although they reach the Thames in a highly putrescent form, yet such is the influence of dilution, agitation, and oxidation, that their putrid property is quickly lost.

3d. That the mischief which really results from the present mode of disposing of the sewage is caused by the *insoluble* organic matters which collect upon the banks of the river near to the sewers, and there undergo perpetual putrefaction.

4th. That this may be obviated by defecating the sewage by means of lime, and allowing the clear liquor only to be discharged into the Thames; or by discharging the sewage into the Thames in such a manner that it will mix with and be diluted by 200 or 300 times its bulk of water.

And lastly. That the most effective means of improving the condition of the river and of protecting the public health is the embankment of the Thames; for the removal of the offensive mud and the submerging of the river's banks are, in my opinion, the most important of all considerations.

50. On the 7th July 1858 Captain Galton and Mr. Simpson sent to the First Commissioner a reply to Messrs. Bidder, Hawksley, and Bazalgette's Report, which they commenced with the following complaint:

The question under discussion is so important that it is to be lamented that the Metropolitan Board of Works did not refer its consideration to an unbiassed tribunal; and we regret that Mr. Bidder, Mr. Hawksley, and Mr. Bazalgette, have, in their report, misrepresented our statements, and have founded upon these misrepresentations arguments adverse to our conclusions.

They defended their former propositions at considerable length; but it is only necessary to extract some of their conclusions, referring to the propositions of the Metropolitan Board's engineers.

That the limited provision for rainfall in the sewers proposed by Messrs. Bidder, Hawksley, and Bazalgette, would cause the sewage too frequently to overflow into the Thames within the metropolitan district.

That the proposition to throw the whole sewage of the metropolis in a concentrated mass into the Thames at Barking, close to the metropolitan boundary, would not prevent the sewage from returning within the metropolitan limits, and would be injurious to those eastern districts of the metropolis which lie adjacent to the Thames, the population of which is rapidly extending in consequence of the great increase of the commerce of the port of London.

That the embankment of the Thames is desirable as a means of preventing deposits of mud on the foreshores, but it will not effect the purification of the river.

This was replied to by Messrs. Bidder, Hawksley, and Bazalgette, on the 20th July; a rejoinder appeared on 16th August, and the controversy (which had taken a somewhat acrimonious and personal tone) was closed by a letter from Mr. Bidder. dated 20th September 1858.

### State of the Thames, 1858.

51. During the discussions and disputes that were taking place on the main drainage system the state of the Thames was becoming daily much worse, and was exciting great alarm and indignation. The subject was repeatedly noticed in Parliament, and strong language was used in both Houses.

In the House of Commons, on 11th June, Mr. Brady said, "it was a notorious "fact that hon. gentlemen sitting in the committee rooms and the library were utterly "unable to remain there in consequence of the stench which arose from the river."

On 15th June Mr. Mangles said: "By a perverse ingenuity one of the noblest of "rivers had been changed into a cesspool;" and, on the 17th, Mr. Palk described it as "one vast sewer, which would surely spread disease and death around." On the 18th a long debate took place on what was termed "the pestilential condition of "the Thames," and "the vile state of that magnificent river."

Similar complaints were made in the House of Lords. On 25th June the Earl of Hardwicke said the Thames had been "made the main sewer for the whole of London, "and had been converted into a most abominable ditch." "The gaseous matter "flowed along with the river, and at high water the state of the atmosphere was "worse than at any other time of the tide." Earl Grey said it was impossible that "such a stench should not be exceedingly dangerous."

The result of this agitation was that, as a temporary measure, the Government sanctioned a series of remedial operations by mixing lime with the sewage before its discharge into the river. This was carried on by the Metropolitan Board at a large expense for a considerable time.

### Alteration of the Law, and Construction of the Main Drainage Works, 1858–1875.

52. The Metropolitan Board received the report of Messrs. Bidder, Hawksley, and Bazalgette, at the beginning of April 1858, but they delayed its consideration for some time, and the main drainage appeared to have come to a deadlock.

Meanwhile there had been a change of Government. In February 1858 Lord Palmerston went out of office, and the Earl of Derby became Prime Minister; and, as a consequence of this, the office of First Commissioner of Works was transferred from Sir Benjamin Hall to Lord John Manners.

In one of the debates on the state of the river in the House of Commons, on the 18th June 1858, the former gentleman, now in opposition, complained of the Metropolitan Board having let the whole summer pass without any care for the state of the Thames or the condition of the inhabitants of the metropolis. He added:—

He thought that the time had now come when the Government should consider whether it would not be better to take the whole of this great work into their own hands; whether they should not appoint some Commission of able and responsible persons, subject, of course, to the approval of the Treasury, and leave it to them to carry out both the main drainage of the metropolis and the embankment of the Thames, works of such magnitude that it was impossible that they could be paid for wholly out of local rates.

This notice appears to have stirred the Metropolitan Board to action, for, on the 29th June, they passed a resolution approving the main features of Messrs. Bidder, Hawksley, and Bazalgette's scheme, and appointed a deputation to submit it to the new First Commissioner.

The interview took place on the 1st July. The chairman described the nature of the works proposed, and proceeded to point out some of the difficulties which impeded

the free action of the Board, in consequence of the Act of 1855 rendering it imperative that their designs should be approved by the Government, a condition from which they wished to be relieved.

The change of Ministry brought with it a change of policy in regard to this matter. The party formerly in office had firmly adhered to the principle that the Government had a right to be consulted on a measure of such public importance as the drainage of the metropolis; but the new Administration held a different view, and the result was that on the 15th July the Chancellor of the Exchequer (Mr. D'Israeli) moved for leave to bring in a Bill the object of which was to relieve the Board of Works from the necessity of Government sanction, on the ground that, as the metropolis paid for the work, they had a right to construct it in any way they pleased; or, as the First Commissioner afterwards expressed it, "He who pays the fiddler has a right to call the tune."

The proposal was received with much criticism. The discussions on the subject had become widely known; the subject was warmly taken up, and stormy debates occurred at every stage of progress of the Bill in both Houses; but the views of the Government ultimately prevailed, and the Bill became law on the 2nd August 1858.

53. This Act, 21 & 22 Vict. cap. 104., was entitled "An Act to alter and amend "the Metropolis Local Management Act (1855), and to extend the powers of the "Metropolitan Board of Works for the purification of the Thames and the main "drainage of the Metropolis."

It repealed the obnoxious provisions of the former Act, and substituted the following:—

I. The Metropolitan Board shall cause to be commenced, as soon as may be after the passing of this Act, and to be carried out and completed with all convenient speed, according to such plan as to them may seem proper, the necessary sewers and works for the improvement of the main drainage of the metropolis, and for preventing, as far as may be practicable, the sewage of the metropolis from passing into the River Thames within the metropolis.

Borrowing powers were given to the extent of 3,000,000*l.*, and the time for executing the works was extended to the 31st December 1863.

The Board were also bound to avoid causing any nuisance, and were liable to indictment in case of the infringement of this provision.

54. It certainly appears somewhat remarkable that the Legislature should have withdrawn all control over the construction of gigantic works of this kind, which were certain to have influences of a wide national character. But, if the debates which occurred at the time are carefully studied, it is not difficult to trace out the reasons which mainly influenced the decision.

In the first place, the state of the river urgently called for immediate action in some way or other. Your Majesty's gracious speech at the close of the session said, "The sanitary condition of the metropolis must always be a subject of deep interest "to Her Majesty, and Her Majesty has readily sanctioned the Act which you have "passed for the purification of that noble river, the present state of which is little "creditable to a great country, and seriously prejudicial to the health and comfort "of the inhabitants of the metropolis."

Secondly, all the contending parties, whose opinions were of any value, agreed that the general principle proposed by the Board, namely, that of intercepting the sewage by main conduits which should carry it away to the eastward, was the correct one to be applied.

Thirdly, in the wide divergence of opinion as to the disposal of the sewage and the points of its discharge into the Thames, it was felt to be impossible for Parliament to undertake the decision between the conflicting views. But it was clearly seen that in any case the carrying out of the intercepting system would be a necessary preliminary measure, and might therefore safely be entered upon at once, leaving the ultimate mode of disposal of the sewage for later decision. In other words, it was considered that the plans of the Board were not necessarily final, but might be extended and amended at a future time, if need should arise. The following extracts will illustrate the views entertained on this point:—

Sir John Shelley said,—

There was nothing in the plan now proposed, he believed, to prevent the sewage being ultimately carried to Sea Reach, if it should be found necessary.

Mr. Lowe said,—

It might be found necessary, after all, to send the sewage down to Sea Reach.

Viscount Palmerston said,—

Complete relief would not be afforded to the metropolis by the expenditure of 3,000,000*l.*, and if tunnels [main sewers] were constructed to Barking Creek, the Metropolitan Board of Works would have to come to Parliament and say, "You sanctioned this work, but by limiting the expenditure you forced us to adopt a "plan which is essentially and radically defective, and therefore, on the part of the public, we call upon you "to assist us by grants of public money to carry the sewage to another point."

Mr. Robert Stephenson said,—

Whether or not it might be necessary hereafter to go down to Sea Reach, was not a question for the House now to decide. Meanwhile, let them be contented to go down to Barking Creek. For his part, he thought it important not to go too far down the river in the first instance. * * * Even supposing they finally carried the outfall down to Sea Reach, much in a monetary point of view would be gained by not adopting that plan in the first instance. Moreover, he believed that sewage matter would eventually be made useful for agricultural purposes, and he therefore thought it impolitic to enter into any larger expenditure than could well be helped for the present, if even it were found necessary to carry the sewers down to Sea Reach hereafter.

Lastly, there was a confident expectation that, although the sewage would be discharged in the first instance at what was considered by many to be an objectionable point, it would be treated by some process of deodorization before entering the Thames. The following extracts from the debates show this:—

Lord John Manners said,—

He thought the Metropolitan Board of Works had done wisely and well in determining that, should they fix on the points of outfall at Barking Creek and Crossness Point, they would deodorize the sewage there during six months in the year.

Mr. Tite said,—

The evidence clearly showed that, if they deodorized the sewage, it mattered little at what part the sewage water was turned into the river. Therefore it would be unnecessary to continue the limits within which the outfalls were not to be made.

Mr. D'Israeli said,—

We make it a condition with the Metropolitan Board of Works * * that provision shall be made for such temporary and *permanent* works of deodorization as the metropolis has a right to require.

Mr. Lowe said,—

The plan of the Metropolitan Board of Works was that the sewage * * should be discharged into a reservoir at Barking Creek * * whence, having undergone a process of deodorization by lime, it should be discharged into the Thames.

Sir John Shelley said,—

It was hardly fair that * * that process was insisted on during only six months.

Mr. Robert Stephenson—

Quite admitted that some parts of the metropolis could not be drained except by deodorization.

Mr. Akroyd—

Objected to the scheme of deodorizing only for six months in the year, as the sewage thus poured out in the winter months would form mud banks which would ferment and poison the atmosphere in summer. They ought to insist upon deodorization for the whole year.

Mr. Pullen said,—

In the report of the Committee of the House on the subject it was stated that no plan ought to be regarded for the sewage of the metropolis which did not provide for one of two things; either that it should be taken down the river so far from the metropolis that it could not be brought back by the action of the tide, or else that it should be deodorized, and only the purified liquid part of it discharged into the river.

The Earl of Derby said,—

It is generally understood, although there is no express provision in the Bill to that effect, that the *modus operandi* is to be by intercepting sewers, whereby the sewage of the metropolis will not be allowed to be poured into the river until it shall have undergone, at such place or places as may be determined on, the process of deodorization.

It has also been shown by the extracts we have given from Messrs. Bidder, Hawksley, and Bazalgette's Report, (paragraphs 46, 48, and 49), and by the evidence before this Commission, QQ. 8622 to 8626, that some process of deodorization before discharge was originally contemplated by the Metropolitan Board as a possible necessity, and for which accordingly some provision was made.

55. Immediately after the passing of the Act the Metropolitan Board took the matter earnestly in hand. The designs were speedily completed, and contracts were entered into for the construction of the works.

In 1863 these had so far advanced as to admit of temporary arrangements for the discharge of a portion of the northern sewage at Barking. The northern and southern

outfalls were both completed and in use in 1864. At that date the Board calculated that nearly one third of the metropolitan sewage had been diverted, and the diversion resulted immediately in a greatly improved state of the river within the metropolitan area.

In 1865 the works were still further advanced, and the great drainage system was formally "opened" by H.R.H. the Prince of Wales on the 4th of April in that year.

There still, however, remained some important parts incomplete, the chief of which were the great low-level sewer on the north side (which was delayed by the construction of the Thames Embankment, of which it formed a part), and also some large pumping stations. These took some time, and it was not till the year 1875 that the works were pronounced complete.

Subsequently to the commencement of the works a considerable change had been made in their extent by the addition of what is called the "Western Division," including Fulham, Chelsea, Brompton, Kensington, Shepherd's Bush, Hammersmith, and part of Acton. The Board originally intended to deodorize or utilize the sewage of this district in its own neighbourhood, rather than incur the costly process of carrying it to Barking, and lifting it twice on its route to that place. But on further consideration, and in deference to the wishes of the inhabitants and others, they subsequently adopted the latter plan, and included it in the northern low-level system of metropolitan drainage.

## Enlargements found Necessary, 1881–2.

56. In the report of the Metropolitan Board for 1881 occurs the following passage:—

> The floodings from heavy storms of rain which have occurred on several occasions in recent years in some of the populous suburbs of London, principally those on a low level, made it necessary for the Board to determine upon the construction of some additional large sewers to carry off the storm water. The new sewers which the Board, after careful consideration, resolved to construct were these—
>
> 1. Storm relief line for the Ranelagh and King's Scholars Pond Sewers.
> 2. Storm relief line for the Ratcliff Highway and Limekiln Dock Sewers. Relief line for high level sewer at Hackney.
> 3. Intercepting sewer from Putney to Clapham. Storm relief to high level sewer at High Street, Clapham, to discharge into Effra Creek, Vauxhall.
> 4. Deptford storm overflow.
> 5. New sewer from Deptford Broadway to Lee Bridge.
> 6. Sewer to relieve low-lying ground at Walworth.
> 7. Storm sewer to relieve Holloway and Kentish Town.

These sewers will have storm outlets into the Thames. Sir Joseph Bazalgette gives (QQ. 26 to 34) further particulars about them, and states that their cost will be 1,500,000*l.*

The same report also says:—

> The Board has lately resolved to enlarge the reservoirs at the Barking and Crossness outfalls to about 50 per cent. beyond their present capacity, so as to admit of the largely increased quantity of sewage being stored in the reservoirs until the ebb tide, instead of, as has occasionally been necessary, having to be discharged on the flood tide, and thus giving rise to complaints that the Thames water at Woolwich was rendered impure. The specification and drawings of the works are in course of preparation.

Sir Joseph Bazalgette gives (Q. 76) further explanations about these reservoir enlargements, and estimates their cost at 160,000*l.*

## The Thames Embankment, 1860–1874.

57. It had been agreed on all hands that, in conjunction with the diversion of the sewage, it would be desirable to carry out plans which had been proposed at an early period for the embankment of the Thames through the metropolis. The offensive state of the river had been greatly enhanced by large areas left dry at low water, on which sewage matter collected and putrefied; and the proper way of removing this cause of mischief was by confining the current within a narrowed channel.

In 1860, and again in 1861, public inquiries were undertaken on the subject, and, after some discussion as to the manner in which the work should be constructed, an Act was passed in 1863, entrusting its execution to the Metropolitan Board. This was followed by other Acts. The work was proceeded with, and was finished about 1874.

## Attempts to Utilize the Sewage, 1860 to 1873.

58. Soon after the Metropolitan Board had begun the main drainage works, they took up the question of the possibility of utilizing the sewage of London.

At that time considerable differences of opinion existed as to whether sewage could be profitably applied to land on a large scale, and the Board considered that their best course was to get private enterprise to aid them in effecting the object. With this view, in the beginning of 1860, they issued public advertisements inviting proposals for taking the sewage. Several answers were received and discussed, but as in the meantime Parliament had taken up the general subject, the Board determined to wait the result of their inquiry.

In 1862 a committee of the House of Commons was appointed, on the motion of Dr. Brady, to inquire "into the best means of utilizing the sewage of the cities and "towns of England." Their report was laid before the House in July 1862, and was generally to the effect that the value of the sewage varied greatly under different circumstances, but that municipalities had not sufficient powers for its most profitable application.

The Board again advertised early in 1864, hoping, as they said, that some plan would be produced whereby "a remunerative profit would be afforded to the pro- "jectors, and some pecuniary means provided for the reduction of the burthens of "metropolitan taxation, thereby assisting the Board to carry out many works of "public improvement urgently required in the metropolis."

More plans were sent in, and a decision was about to be made, when, in April 1864, Lord Robert Montagu obtained the appointment of a second committee in the House of Commons to investigate the matter. The report of this committee was much more positive than the former one, as they expressed an opinion that it was not only possible to utilize the sewage of towns by conveying it in a liquid state through pipes to the country, but that such an undertaking might be made to result in pecuniary benefit to the ratepayers of the town whose sewage was thus utilized.

On this, the Board sent a deputation to visit some towns where sewage irrigation was applied, and, being then convinced that the time for action had arrived, they resolved to accept one of the offers submitted in answer to their advertisements, namely, that of Messrs. Hope and Napier.

59. These gentlemen proposed to construct works for enabling them to take the dry weather sewage of the northern area of the metropolis, and to conduct it by a conduit some 40 or 50 miles long down to the Maplin Sands on the Essex coast, where it was to be applied to the reclamation and irrigation of a large tract of land. Powers were also to be taken to supply sewage to the country all along the line of conduit. A company was to be formed, with a capital of 2,100,000*l.*, and the profits were to be divided between it and the Metropolitan Board.

Messrs. Hope and Napier introduced a Bill into Parliament which was opposed and discussed in Committee, but was ultimately passed on the 19th June 1865, and the Company was formed under the name of "The Metropolis Sewage and Essex "Reclamation Company."

Doubts having been expressed by Baron Liebig and other scientific men as to the feasibility of the scheme, the Company, in order to afford a practical test of its merits, took, in 1866, a large piece of land at Barking, and established there a model sewage farm, supplied directly from the northern metropolitan outfall sewer. The results of this trial were reported as very satisfactory.

It was stipulated that the main conduit to the Maplin Sands should be finished within four years after the passing of the Act. It was commenced towards the end of 1865, but the operations upon it soon ceased, and in 1866 the Company obtained an amending Act extending the time of completion till July 1876.

In the session of 1871, nothing more having been done, the Metropolitan Board promoted a Bill in Parliament for setting aside the arrangement, and at the same time the Company introduced a counter-Bill, to enable them to modify their proposed plan of operations. The House of Commons rejected both Bills, thus leaving the matter where it was before. No further notice has been taken of the subject in the reports of the Metropolitan Board.

60. In regard to the sewage from the south side of the metropolitan area, several offers were received and considered at various times, but no agreement was come to.

In 1870 the attention of the Board was called to the method of sewage treatment adopted by the Native Guano Company, commonly called the A. B. C. process. They visited the Company's works at Leamington, and, after some negotiation, they assented to a proposal of the Company to put down, at their own expense, experimental works at Crossness, to show how they could deal with the sewage discharging there.

The trials were begun in August 1872, and lasted till the end of November in that year. The Company treated about $\frac{1}{343}$ part of the whole Crossness sewage, and they produced a large quantity of solid manure.

The experiments were carefully watched by the engineering and chemical officers of the Board, who reported fully on them in January 1873. It was recorded that the condition of the effluent water was found to be, on the whole, very good, and no offensive effluvia or nuisance resulted from the preparation of the manure.

But when the financial part of the proceeding was examined, the Board came to the conclusion "that there was no proof that the process could be adopted with any "hope of profit to the rate payers," and as this hope of profit appeared to be their only inducement for defecating the sewage, they dismissed the Company, and made them at once remove their works and plant from the ground.

## Former Public Inquiries as to alleged Evils resulting from the Sewage Discharge.

61. There have already been two public inquiries on this subject, which it will be convenient briefly to notice.

### *Mr. Rawlinson's Barking Inquiry*, 1868.

The discharge of sewage at the Barking outfall commenced in 1863, but it was not till 1865 that the works were formally opened and the full quantities of sewage were discharged.

The outfall had not been long in use before complaints arose. In May 1868 a memorial was addressed to the Home Secretary from the inhabitants of Barking, calling attention to the condition of the Thames in consequence of the discharge of sewage through the main outfalls.

The Home Secretary, after communicating with the River Conservancy and the Metropolitan Board, ordered an inquiry, which (after some delay caused by a change of administration) took place at Barking in June 1869, the officer appointed to hold it being Mr. (now Sir) Robert Rawlinson; C.B., Chief Engineering Inspector to the Local Government Board.

The inquiry lasted five days; the memorialists and the Metropolitan Board were represented by counsel, and many witnesses were examined, among whom were, for the former, Capt. Burstal, Mr. Leach, and Mr. Hope; and for the latter, Messrs. Bazalgette, Bidder, Hawksley, Gregory, Hawkshaw, Haywood, Hemans, Dr. Miller, and Dr. Odling.

Mr. Rawlinson made his report in November 1869, and it was afterwards published as a Parliamentary Paper (No. 7 of 1870).

The memorial alleged, in substance, that the river was silting up to such an extent as to be dangerous to navigation, and that its pollution was dangerous to the health of the inhabitants of Barking and of all the populous towns below London.

The inquiry took a wider range than was anticipated, and Mr. Rawlinson's conclusions were as follow:—

That the allegations in the memorial have only been partially proven.

That the memorialists are not in a position to establish deterioration of health to emanations from the metropolitan main sewerage outfall works, as the town of Barking is without local governing powers, is unsewered, contains many cesspools, a sewage-tainted sub-soil, and has a defective water supply.

That the River Thames is polluted by the metropolitan sewage and receives such road and street detritus as the aforesaid sewage contains.

That the main channel of the Thames has not been reduced in depth of water by such detritus.

That Barking Creek has not been closed to vessels of 250 tons burden.

That fish have been destroyed in the creek, but most probably by chemical refuse.

That an accumulation of mud has taken place, both on the shore of the Thames and at the mouth of Barking Creek, but from what special cause has not been proven.

That the Metropolitan Board of Works, in their annual reports, recognize their obligation to purify the Thames, and to effect this purpose have negotiated with second parties for the utilization of the northern sewage by irrigation.

That the Board, throughout their transactions for the utilization of sewage, have stipulated for pecuniary relief to the metropolitan ratepayers.

That the Metropolitan Board have objected to the admission of sewage into the Thames from towns situate above London, and, therefore, inferentially justify the objections to river pollution below London.

That deodorization and disinfection of the metropolitan sewage, by chemicals, would be very costly to the ratepayers, and in the results imperfect.

That river pollution by town sewage, in the case of the Thames, may be prevented.

The following additional extracts from the report will be useful as showing the opinions which Mr. Rawlinson was led to form by the evidence laid before him :—

The complex questions of tidal flow and of scour, of the accumulation of mud banks in specified parts, and of the weight of detritus brought from the metropolitan road and street surfaces, mixed with the sewage and discharged into the Thames, I cannot pretend to settle There are, however, the simple facts that all town sewage does contain certain proportions of solids, which solids can neither be oxydized nor annihilated; and, therefore, however small or however large in quantity they may be, if turned into the Thames, they must ultimately deposit somewhere. There is also the additional fact that the London sewage is discharged into the Thames, with whatever detritus there may be, just as it flows down the main sewers. It was contended by the engineer to the Metropolitan Board of Works that streets and roads within the metropolitan area are far better scavenged than those in provincial towns, such as Birmingham, and that all the detritus which can be retained is regularly emptied from the numerous gullies, or is raised by hand from the tributary sewers. Admitting the general regularity and perfection of London street and road scavenging, yet very dirty (muddy) streets are seen occasionally, and no mechanical arrangements of gulley catchpits can prevent some of this mud and detritus flowing with the vast volume of sewage to the outlets.

* * * * * *

The evidence given at the inquiry is clear and distinct that the navigation of the Thames has not been endangered; there is no loss of water in the main channel; neither do the engineer nor secretary to the Thames Conservancy Board anticipate damage to the low water main channel; the movement of steamers up and down, with the scour of the tides and land floods, being sufficient to keep the waterway open; any extra deposit of silt is on mud banks and the shores betwixt low and high water.

No medical proof was given by evidence that the health of the inhabitants of the parish of Barking and other populous and industrious towns below London suffered in consequence of the discharge of sewage through the metropolitan main sewerage outfall works. The men and their families situate at and over these works, it was stated, do not suffer specially.

* * * * * *

The banks and shores of such tidal estuaries are constantly altering by this unceasing scour, and there is as constant a redeposit of the sand and mud from the flood and tidal waters, so that it would be very difficult to define (legally) where any increase of deposit has come from, in the Thames at Barking. There is, however, the simple fact that *all the detritus* brought down by the metropolitan sewers, much or little, passes, at present, with the sewage direct into the River Thames; and that portion of detritus which is not soluble in water must be deposited, part on the shores in the mud found there, and part on the estuary banks;—annihilation is impossible.

* * * * * *

The purification of the Thames is of the utmost importance; the task of its accomplishment, as imposed by Parliament, rests upon the Metropolitan Board; and negotiations with private companies, if they fail, cannot free the Board from this responsibility. If the works can be executed without loss, the metropolitan ratepayers have a right to be exonerated from any charges; if there accrues an income above a stipulated percentage, they ought to share the profits; but if the work of freeing the Thames from pollution can only be accomplished by a rate in aid, it is the duty of the Metropolitan Board to meet this difficulty, and to levy such rate as may be required.

* * * * * *

The Metropolitan Board have evidently fettered themselves throughout with striving to obtain what they consider the full value of the sewage, when this ought to have been a secondary consideration, prevention of pollution to the Thames being the first consideration.

* * * * * *

With respect to the existing sites of the outfalls at Crossness and Barking, * * * all things being considered, I think no more appropriate places could be found, if sewage irrigation is ultimately to be carried out. The entire works have been well executed in every respect.

* * * * * *

The mud found on the banks and shores of the Thames in Barking Reach, upon analyses by Drs. Miller and Odling, is found not to differ in its chemical elements from Thames mud generally, as deposited on the shores of the river from Teddington to Erith.

* * * * * *

If, hereafter, Parliament enacts that rivers shall not continue to be polluted by town sewage (and the Thames is not exempted), ways to complete sewage irrigation works must and will be found. The manurial value of town sewage has over and over again been settled by the most eminent chemists, and the practicability of using it in agriculture, beneficially, is year by year being tested and proved.

### *The Thames Conservancy Mud-bank Inquiries*, 1867–80.

62. Although the complaints of the inhabitants of Barking had been shown to be, in a great measure, groundless, they were not the only parties who were alarmed about the state of the Thames, as the subject had attracted the attention of the body most especially interested in the river, namely, the Thames Conservancy Board.

This body had for some time been making surveys and observations on the bed of the river, and in 1867 and 1868 chemical analyses had been made for them by Dr. Letheby of the constituents of the mud collecting near the outfalls. Immediately after the appearance of Mr. Rawlinson's report they gave notice of a Bill in Parliament,

one of the objects of which was to prevent the Metropolitan Board of Works from discharging from their outfalls without previous deodorization. The Bill was strongly opposed by the Metropolitan Board in committee, and the result was a compromise, the Bill being allowed to pass in an altered form. It was called the "Thames Navigation Act, 1870," and contained the following provision:—

XX. The Metropolitan Board of Works shall, at their own expense, keep the Thames free from such banks or other obstructions to the navigation thereof as may have arisen or may arise from the flow of sewage at their outfalls for the time being into the river. And, for the purposes aforesaid, the said Board shall have full power and authority from time to time to dredge the said river, and to remove such banks or obstructions; but all such dredging operations shall be subject to the approval of the Conservators, and, if they so require, be carried on under their superintendence.

Section XXI. provided that, if any difference should arise as to the origin of any banks or obstructions to the navigation, it should be determined by arbitration.

In 1873 further analyses were made, and in July 1874 the Thames Conservators formally complained to the Metropolitan Board that increase of deposit was forming in the bed of the river near the outfalls. The Board disputed the fact, and some further correspondence ensued.

In 1875, 1876, and 1877, the analyses were repeated by Dr. Letheby and Professor Williamson, and in June of the latter year the Conservators instructed Captain Calver, R.N., F.R.S., to make an examination of the river bed, its shoals and deposits, and the way in which these were affected by the discharge of the metropolitan sewage; also into the changes in the channel, and the question of sewage and river currents.

Upon these points Captain Calver, on the 15th October 1877, made a long report to the Conservators, the conclusions at which he arrived being mainly as follows:

That offensive accretions had recently formed within the channel of the Thames; that a material portion of these were in the neighbourhood of the sewage outfalls, and had formed since the outfalls came into operation; that the constituents of these accretions were the same as those of the sewage, and that the latter was discharged in sufficient quantity to account for them, the tidal streams in the neighbourhood of the outfalls being the effective cause. He further expressed the opinion that the increase of soil in Woolwich Reach and elsewhere above the outfalls had been derived from the sewage discharge, and that the operation of accretion had been effected by the superior disturbing and transporting power of the flood stream.

The Conservators sent this report to the Metropolitan Board, and requested them to carry out the terms of the Act. The Board, on this, directed its engineering and chemical officers to institute an inquiry into the facts, and in April 1878 a report was made by Sir Joseph Bazalgette, Messrs. Law and Chatterton, and Messrs. Keates and Dupré, strongly challenging the statements of Captain Calver in every particular. Replies and rejoinders followed, but as no agreement appeared possible, in 1879 the Conservators determined to appeal to the powers of the Act of 1870; and in the middle of that year it was arranged that an arbitration should take place, under the 21st section of that Act, to try the question.

It was decided at the outset that the inquiry should be entirely confined to the origin of three particular banks in the river, near the outfalls (called Margaretness Bank, Barking Bank, and Crossness Bank respectively), and as to their being obstructions to the navigation; and that the question of the pollution of the river by the flow of sewage at the outfalls should not be gone into.

The arbitrators sat twenty-five days, between November 1879 and March 1880, and made their report on the 24th April 1880.

They took a great deal of evidence in regard to the sewage question generally, and they determined—

1. That the banks in question had not obstructed the navigation further than by making the main channels somewhat more crooked.
2. That they had arisen from the effect of dredging operations.
3. That the water in the tidal portion of the Thames contained a considerable amount of suspended matter, derived partly from the basins of the Thames and its tributaries, partly from the washing away of the foreshores of the tidal estuary where unprotected, partly from material brought up from the mouth of the river by the flood tide, partly from sand and mud stirred up in the course of dredging operations, partly from denudation of the river bed, partly from sewers in districts outside the metropolitan area, and partly from the sewers of the Metropolitan Board. The proportion contributed from this latter source was small as compared with the total amount of suspended matter in the whole volume of tidal water flowing past the outfalls on every tide.

4. That the three banks were composed of matter which had been held in suspension in the water, and had been derived from the several sources above-mentioned. Whilst, therefore, the sewage from the metropolitan outfalls might have contributed to their contents, the three banks could not be said, in the sense of the Act of 1870, to have arisen from the flow of sewage at the outfalls; and the Metropolitan Board should not be called on to remove or contribute any portion of the expense of removing them.

# PART II.

## THE SYSTEM UNDER WHICH SEWAGE IS DISCHARGED INTO THE THAMES BY THE METROPOLITAN BOARD OF WORKS.

63. The system of the Metropolitan Main Drainage, as actually carried out, has been fully explained to us by Sir Joseph Bazalgette; and before offering any remarks on it we may give a brief description of its more important features.

### General Principle.

64. The general principle of the Metropolitan Main Drainage System is that of *interception*.

According to the natural hydrographical features of the district, the portion of the Thames Basin on which the metropolis stands is drained by transverse streams flowing into the river on each side; and the sewers, which have been formed from time to time to effect the artificial drainage, have been made to follow the lines of these streams.

In order, therefore, to prevent these sewers from discharging into the river, the principle has been adopted of *intercepting* them by lines of conduits lying nearly at right angles to them, *i.e.*, in the same general direction as the course of the river, but inclining towards it. These conduits fall in an easterly direction, and are continued down to points on the banks of the river below London, where the sewage, intercepted and carried off by them, is discharged.

In such of these intercepting conduits as are at sufficient altitude, the sewage flows away by gravitation. But as many parts of the metropolis lie so low as to render this impossible, the contents of the intercepting conduits there have to be pumped up by steam power, in order to raise them to the necessary level of discharge.

The entire system (which is shown on the map marked Appendix B.) is naturally separated into two great divisions, lying on the north and south of the river respectively.

### Northern Interception.

65. On the north side there are three great lines of interception;—

1. A line called the *Northern High Level Sewer*, which, beginning in the north-west at Hampstead and Highgate, passing by Hackney, descending by Stratford, and crossing over the River Lea near Bow, abuts upon the Thames at Barking Creek. This conduit acts entirely by gravitation.
2. A line at a lower level called the *Northern Middle Level Sewer*, which begins in the west at Kensal Green, passes through Oxford Street, Clerkenwell, and Bethnal Green, and joins the Northern High Level Sewer near Bow. This conduit also works entirely by gravitation.
3. A line at a still lower level called the *Northern Low Level Sewer*. It begins in the extreme west at Chiswick, and passes through Chelsea, near the bank of the river, as far as the Grosvenor Road, Pimlico. Here, near the Victoria Railway Bridge, its contents are pumped into another conduit lying slightly higher, which runs along the northern Thames embankment, and near the river to the Tower, then striking off to the north-east through Stepney to Abbey Mills, near Stratford, where the contents are again pumped up to the level of the Northern High and Middle Level Sewers.

From this point the whole of the northern drainage flows through the *Northern Outfall Sewer* to the Thames; this outfall sewer is formed of three parallel conduits, which take the contents of the three sewers, but can be made to communicate when necessary to equalise the flow.

## Southern Interception.

66. On the south side of the river there are two great lines of interception,—

1. A line called the *Southern High Level Sewer*, which begins at Balham and passes through Clapham, Brixton, Camberwell, and New Cross, crosses under Deptford Creek by iron syphon pipes, and continues through Greenwich, Woolwich, and Plumstead Marshes to a pumping station on the right bank of the river at Crossness. The sewage reaches that point by gravitation.
2. A line called the *Southern Low Level Sewer*. It begins in the extreme south-west at Putney, and passes through Wandsworth, Battersea, Vauxhall, Kennington, Peckham, and New Cross, to a pumping station on the Ravensbourne, near Deptford, where the contents are pumped into the Southern Outfall Sewer.

At a certain point near Nine Elms there is a pumping station, which lifts into this sewer the drainage brought down by the sewers on the River Effra.

There is also a branch conduit from the districts of Bermondsey and Rotherhithe, which delivers to the Deptford pumping station, the contents being then pumped into the Southern Outfall Sewer.

From Deptford the united sewage flows down to Crossness by the *Southern Outfall Sewer*.

At Crossness the whole is pumped by steam power to the height necessary to allow it to flow into the river.

67. The following data furnished by Sir Joseph Bazalgette (see Q. 12,502) will give a general idea of the magnitude of the works:—

| Areas from which Sewage is intercepted. | | | | Length of Main Intercepting Sewers, including Branches. | Dimensions, Largest and Smallest. | Inclinations, Greatest and Least. |
|---|---|---|---|---|---|---|
| North Side of Thames. | Inside Metropolis. | Outside Metropolis. | Total. | | | |
| | Square Miles. | Square Miles. | Square Miles. | Miles. | | Feet per mile. |
| High Level | 8·29 | — | 8·29 | 7⅓ | 9′ 6″ × 12′ 0″ Barrel – 4′ 0″ | 75 to 4. |
| Mid Level | 16·47 | Kilburn 1·34, S. Hornsey 0·37 = 1·71 | 18·18 | 12¾ | 10′ 6″ Bl. – 4′ 0″ × 2′ 8″ | 17½ to 2. |
| Low Level, including Western Division | 23·74 | — | 23·74 | 21 | 10′ 3″ Bl. – 3′ 9″ × 2′ 6″ | 10·37 to 2 |
| Outfall Sewer | — | — | — | 5½ | 3 Culverts, 9′ 0″ × 9′ 0″; 2 Culverts, 9′ 0″ × 9′ 0″ | 2. |
| | 48·50A | | 50·21C | 46¾ | | |
| Area of Metropolis [North] *not* drained into intercepting sewers. | 1·47B | | | | | |
| | 49·97 | | | | | |

A. Of this area 3·40 square miles is common or park land, and 0·87 square miles is water.

B. This area consists of parts of Hackney Marshes, North Woolwich, and a detached part of the Metropolis near Muswell Hill.

C. In addition to the above, the district of the Hornsey Local Board contributes sewage from a present population of about 22,000, the quantity being restricted ultimately to 500 cubic feet per minute. A part of the Stamford Brook drainage area contributes also the sewage from a small population, but its number cannot be ascertained. The same area also contributes surface water to the Metropolitan system, but the Metropolitan Board have determined to intercept this from their sewers and discharge it into the river at the extreme western boundary of the Metropolis. This is one of the works included in the 1,500,000*l.*, to be expended to prevent floodings from rain.

| Areas from which Sewage is intercepted. South Side of Thames. | Inside Metropolis. | Outside Metropolis. | Total. | Length of Main Intercepting Sewers, including Branches. | Dimensions, Largest and Smallest. | Inclinations, Greatest and Least. |
|---|---|---|---|---|---|---|
| | Square Miles. | Square Miles. | Square Miles. | Miles. | | Feet per mile. |
| High Level | 24·71 | Upper Norwood, 0·54 | 25·25 | 14⅝ | Two 10′ 6″ × 10′ 6″ - One 3′ 0″ × 2′ 0″ - | 52·8 to 2½. |
| Low Level | 20·72 | | 20·72 | 14⅛ | Two 7′0″ × 7′0″ One 4′ 0″ Bl. - | 4½ to 2. |
| Outfall Sewer | 5·78 | | 5·78 | 7½ | 11′ 6″ | 2. |
| | 51·21D | | 51·75F | 36¼ | | |
| Areas of Metropolis (South) *not* drained into intersecting sewers. | 16·57E | | | | | |
| | 67·78 | | | | | |

D. This contains 3 square miles of common land and park, and 0·56 square mile of water.

E. This contains ½ square mile of common land and parks, 3½ square miles of marsh lands, 2·15 square miles draining away from the Metropolis, and the rest in land of a rural or agricultural character, situate in the localities of Roehampton, Eltham, and Mottingham, which will never probably be more than sparsely built over.

F. In addition to this, 0·92 square mile of Beckenham contributes sewage only to the intercepting system.

PUMPING STATIONS.

| | Total Nominal Horse Power. | Lift. |
|---|---|---|
| | | Feet. |
| For Northern Sewage. | | |
| Pimlico | 480 | 18 |
| Abbey Mills | 1140 | 36 |
| For Southern Sewage. | | |
| Deptford | 500 | 18 |
| Crossness | 1000 | 10 to 30 |
| For Storm Relief Overflows. (South Side only.) | | |
| Effra | 200 | 5 to 18 |
| Falcon Brook | 200 | 3 to 10½ |

## Arrangements at the Main Outfalls.

68. The outfall sewers do not discharge directly into the Thames; they terminate in large covered reservoirs, from which the sewage is intended to be discharged only at certain times of the tide. The discharge commences at high water, and it was intended, according to the report of Messrs. Bidder, Hawksley, and Bazalgette, to have been completed "during the first two and a half hours of the ebb tide." As a matter of fact, however, it usually continues for three or four hours, after which time it is intended that the Penstocks are to be closed, allowing the sewage to collect in the reservoirs for discharge on the next tide.

The reservoir at Barking Creek covers about 9½ acres, and holds 35,000,000 gallons, or 5,600,000 cubic feet. That at Crossness covers about 6½ acres, and contains 25,000,000 gallons, or 4,000,000 cubic feet. (In the report of Messrs. Bidder, Hawksley, and Bazalgette, it was recommended that the area of the Barking Reservoir should be about 12 acres, and of that at Crossness about 7 acres.)

The bottoms of the reservoirs are 2·75 feet above ordnance datum, or 1·19 feet above half tide level. At the top they are provided with overflow weirs, from which, when the reservoirs are full, the sewage passes into the river.

At Barking the overflow weirs are at the height of 16·25 feet above ordnance datum, so that the available depth is 13·5 feet. At Crossness the weirs are 2·5 feet higher, giving an available depth of 16 feet.

The works are so constructed that at Crossness the discharge is always below water; but at Barking this is not the case, the discharge partly taking place over the foreshore. The latter arrangement is a departure from the condition laid down

in Messrs. Bidder, Hawksley, and Bazalgette's Report (see *ante*, par. 46) that "in "both cases the sewage should be discharged into the river through submerged "pipes, terminating below low-water mark."

The sewers are capable of bringing down much more than the reservoirs will hold, and when they do so, there will be an overflow into the river from the reservoirs at any time of the tide, as at the storm outlets.

At the beginning of 1881, there were overflows on 43 days from Crossness, and more days at Barking. (See Q. 74.)

It was intended (see Q. 158) that the reservoirs were to be added to from time to time, and it is admitted by the Metropolitan Board that the period has now arrived when more storage room is necessary.

## Capacity of the Main Sewers for Discharge.

69. The capacity of the main intercepting and discharging conduits, as compared with the drainage requirements of the district, involves complicated considerations, in consequence of the double nature of the work to be done.

The drainage of a thickly inhabited area requires the removal, not only of the sewage from the houses, or what may be called the *sewage proper*, but also of the *rain* which falls over the whole area.

70. It has often been proposed to deal with these two elements independently, by establishing a *separate system* of drains for each. This system presents many and great advantages both as regards the removal and the disposal of the sewage proper. It was strongly recommended to the Government by a member of this Commission, in the year 1868, for application to certain towns on the Upper Thames, and it has been carried out at Eton, and in other places, with perfect success and with great benefit.

It was proposed for London in 1854 (as already mentioned in the Historical Notice); but in dealing with such an immense area it has been considered hardly practicable. Sir Joseph Bazalgette says (Q. 9):—

"There are 400,000 houses in London, and the adoption of such a plan would involve redraining every one of these houses. You must put a drain into the house to take the sewage from the waterclosets and the sinks, in fact, from the inside of the house, and you must carry the water from the roof by another drain, separating the two from each house from the very commencement. Now, putting that reconstruction of all the drains of all the houses at 20*l.* per house upon the average, would make 8,000,000*l.* to begin with in the house drainage. Then it is not merely a question of money, but I think you would have a very powerful resistance to any such proposal. I think that every house in London having to be redrained would both on account of the expense and of the immense disturbance that would arise from it, be very strongly objected to. Then that is not all. You would have to use the present system of sewers for the storm water, and to lay an entirely separate set of sewers through the streets for the sewage, with pumping establishments, and so forth. That, we came to the conclusion, could not be done, that, as applied to London, it was an impracticable suggestion."

71. The designers of the London main drainage had therefore to undertake the problem of combining the removal of the sewage and the rainfall in one system, which would have the advantage of using the rain and storm waters to effect the flushing out of the sewers. But they were met by the difficulty that, while the sewage was a comparatively small and a tolerably uniform quantity, the rainfall was a very excessive and a very variable quantity.

Sir Joseph Bazalgette states (Q. 8) that, whereas the maximum flow of the sewage proper of London is not equivalent to a rainfall of $\frac{1}{100}$th of an inch per hour over the whole drainage area, the rainfall amounts sometimes to one, two, three, or even four inches per hour over parts of London.

Further data as to these quantities will be found in the evidence; it may suffice here to state the general principle on which the design was made, and that is given concisely by Sir Joseph Bazalgette in Q. 9. He says:—

"It appeared from tables of rainfall that there were only from 14 to 21 days in the year on which the rainfall exceeded the rate of a quarter of an inch in 24 hours; therefore, we said, if we can divert the sewage from the river in dry weather altogether on all those days excepting the 14 to 21, according to the season (a very wet season has been 30 days), we shall sufficiently divert the sewage from the river to make it clear."

72. The average quantity of sewage actually discharged has been in round numbers as follows, in millions of gallons per diem :—

| — | Crossness. | Barking. | Total. | — |
|---|---|---|---|---|
| 1869 | 48·2 | 35·2 | 83·4 | System incomplete. |
| 1870 | 45·9 | 40·0 | 85·9 | |
| 1871 | 50·8 | 55·0 | 105·8 | |
| 1872 | 61·0 | 63·2 | 124·2 | |
| 1873 | 60·0 | 62·0 | 122·0 | |
| 1874 | 56·0 | 61·9 | 117·9 | |
| 1875 | 64·5 | 74·0 | 138·5 | |
| 1876 | 61·5 | 76·0 | 137·5 | |
| 1877 | 71·2 | 82·2 | 153·4 | |
| 1878 | 74·8 | 82·7 | 157·5 | |
| 1879 | 85·1 | 92·1 | 177·2 | |
| 1880 | 80·9 | 88·8 | 169·7 | |
| 1881 | 74·6 | 89·4 | 164·0 | |

The volumes which the outfall sewers are said to be calculated to carry are—

| | Cubic feet per second. | Millions of Gallons per day. |
|---|---|---|
| For the North - - - | 545 | 294 |
| „ South - - - | 233 | 126 |
| | 778 | 420 |

## Storm Overflows.

73. It is a consequence of the system adopted that there are certain times in the year when the rainfall is so great that the total quantity flowing off must exceed the discharging capacity of the intercepting conduits; and at these times there is no alternative but to allow the superfluous quantity to be discharged directly into the river, independently of the interception, and at the old points of discharge within the metropolitan area.

Suitable arrangements are made for this purpose. The sizes of the intercepting sewers being graduated to take the calculated quantity, at the points of interception of each of the original sewers there is formed a long weir; and when the rain exceeds the calculated quantity, the surplus contents of the sewer flow over this weir and follow the former course down the original sewer, from the mouth of which the fluid escapes directly into the river.

There are 48 of these storm or relief outlets within the metropolitan area, 35 on the north side and 13 on the south. A list of them, showing their positions and dimensions, is given by Sir Joseph Bazalgette in Q. 12,728; they are generally of large size, capable of delivering large discharges when they come into action.

For the prompt relief of certain low-lying districts the storm discharge is aided by steam power. On the banks of the Effra at Nine Elms there is a pumping station of 200 horse-power for lifting the storm waters into the river, when they are penned up by the tide. There is another at the Falcon Brook of the same power.

It is obvious that the fluid discharged from these storm outlets does not consist merely of rain water, but must contain a mixture of sewage.

The present relief by storm overflows is not found sufficient, and very large extensions are now in progress, as explained in the Historical Notice.

## Cost.

74. The total cost of the Main Drainage works hitherto has been stated in the Reports of the Metropolitan Board to be about 4,600,000*l.*

The cost of the further relief works and extension of the reservoirs is estimated at about 1,650,000*l.* more; which will bring the total expenditure to 6,250,000*l.*, as against the original estimate of Messrs. Bidder, Hawksley, and Bazalgette, of 2,300,000*l.*, and of the Referees' alternative scheme of 5,437,000*l.*

## Remarks.

75. The historical notice we have given will show that the Drainage System was decided on under great difficulties, the differences of opinion as to some of the principles of the scheme being very formidable. It became, therefore, an arduous task to settle the plans to be adopted, but the state of the river rendered a prompt decision necessary, and it cannot be questioned that the Metropolitan Board of Works had good grounds for the course they took in the matter. The arguments in favour of a larger scheme, with more distant outfalls, were urged with much force, and by very competent authorities, but the Board had to consider the important conditions of promptness of execution and economy of cost; and as they had reasonable justification for believing in the sufficiency of the scheme they adopted, they cannot be blamed for declining to commit their constituency to what they thought an unnecessary expenditure; especially as an extension of the outfall sewers to a lower point, if necessary, could always be effected at a future time. And, having once decided on their plans, the energy shown in carrying them out with all expedition is deserving of great credit.

To their engineer also, who has been fortunate enough to see the great work carried through from its inception to its successful completion, high praise is due. It is true that the main features had been proposed before he took charge of the work, but this fact in no wise detracts from Sir Joseph Bazalgette's professional skill in re-designing the whole scheme, in all its comprehensive details, and in carrying it through all the intricate difficulties of its construction; so making that practical which before was theoretical only. And it must be observed that, whatever differences of opinion may exist as to disputed points in the design of the works, no question has ever been raised as to their excellence of construction.

76. Then, further, no one can deny the great benefit that has arisen from the main drainage works. The discharge of the sewage into the river within the heart of London had become intolerable, and its interception has exercised a powerful influence in improving the general health of the metropolis. For the system has not only removed an offensive and deleterious element from the most populous part of London, but has also promoted general salubrity by improving the drainage of the entire metropolitan area.

And even granting that some evils may be caused, as we think is the case, by the present mode of discharge, yet these are not of a nature to be compared with those that have been removed by the main drainage scheme.

77. The weakest points of the present system are, the necessity for a large provision of storm outlets, and the discharge of the sewage in its natural crude state.

The *Storm Outlets* are a necessary consequence of the limited general capacity of the intercepting system, and of the sewers having to carry off the sewage and the storm water combined. The question of capacity was argued at much length before the present designs were adopted, as will be seen in our historical notice. The Government Referees urged that a larger system would be necessary, but the advisers of the Metropolitan Board considered their proposals needlessly expensive.

The objection to the capacity has been renewed in evidence before us. Some of the complainants' scientific witnesses have expressed the opinion that the provision for interception is too limited, and that consequently the discharges from the storm overflows within the metropolis are already more frequent, and larger in amount than they ought to be; an evil which, if it exists at present, must increase as the population extends.

It is asserted that there is an error in regard to the estimation of the rainfall to be provided for. For even assuming there were only 14 to 21 days in the year in which there was over a quarter of an inch of rain in the 24 hours, there would be more than that number when the rainfall would exceed one-eighth in 12 hours, or one-sixteenth in 6 hours, either of which would tend to produce overflow.

These allegations are denied by the scientific witnesses of the Metropolitan Board, who contend that the system, with the proposed addition, affords ample provision, not only for the present, but also for the prospective drainage

We cannot, however, lose sight of the important fact, that an expenditure is now going on of the large sum of 1,500,000*l.* for additional "relief sewers" with storm overflows discharging within the metropolis.

78. We are of opinion that the discharges of sewage from the storm overflows, within the metropolitan area, are frequent and considerable, and that they are occasionally of very offensive character.

*Mr. Phillips*, formerly surveyor of the metropolitan sewers, states (Q. 6322, &c.) that "there are hundreds of miles of sewers now in the metropolis in which the sewage "does not flow at the velocity ($2\frac{1}{2}$ feet per second) necessary to prevent the sewage "matters from depositing, and which are called deposit sewers." In these and many other sewers large accumulations take place in dry weather; and when sudden heavy rains occur, as in thunder storms, great masses of filthy material are washed out, and, as the intercepting sewers are gorged by the sudden rain, find their way by the storm outfalls directly into the urban reaches of the river.

We have some evidence of this.

*Captain Marsden, harbour master*, says, July 1879, (Appendix N., and Q. 5356, &c.) On approaching the storm outlet at Ratcliff Creek, I encountered a great quantity of sewage matter of the worst possible kind issuing from that outlet. It could not have been worse if we had been in the sewer itself.

The time was just before low water, and as a natural consequence all this excrement would be carried up the river with the flood tide, polluting and being deposited in the higher reaches.

*Mr. Little, Inspector*, says, December 1880 (Appendix N.), The sewers next below London Bridge, at Dowgate, at St. Paul's, at Blackfriars, and the pumping station Grosvenor Road, were discharging very offensive matter into the river on the 6th and 7th instant.

I have observed this on several occasions during the past week, the discharge prevailing from half ebb and on the young flood.

*Mr. Bowen, deputy harbour master*, says, July 1882 (App. N.), As I rowed past the following storm outlets this morning at 10.30, last quarter ebb, viz., Ratcliff Cross, Bell Wharf, and Coal Stairs, I passed through an immense quantity of *bonâ fide* sewage, and the smell from it was most offensive.

*Mr. P. W. Birch, Mem. Inst. C.E.*, says (9292, &c.), On the 22nd October I had occasion to go up Deptford Creek; it was after a considerable amount of rain; I found the storm overflows were at work, and I saw more solid sewage floating upon the surface of the water than ever in my life before. It was apparently the strongest matter in the form of sewage that I have ever seen. I think that must be a serious disadvantage to people having property in the creek.

79. It is probable the noxious matters which these discharges contain are so speedily oxidized and destroyed by the fresh river water as to become inoffensive and imperceptible. But in this process the free oxygen is abstracted from the water, which is thus rendered less capable of acting efficiently on the larger sewage discharges met with below.

It is stated by some witnesses (Dr. Frankland, for example,) that the condition of the river within the metropolitan area is deteriorating every year, and it is also said that certain banks of offensive mud exist even as high as Westminster bridge; but the evidence on these points is not conclusive. Still, however, the storm discharges, as an element of imperfection in the drainage system, cannot be ignored; it is in evidence they are being largely increased, and it must be borne in mind that if the increase goes on as the population extends, they will probably hereafter diminish to a perceptible extent the advantages of the intercepting system.

This condition of things is to be regretted, but though the storm discharges are locally offensive and disgusting at times, there is no evidence of any injury or serious inconvenience resulting from them above the reach of the influence of the main outfalls.

80. The second weak point in the system as now worked is the *discharge of the sewage in its crude state*, without any attempt to render it less offensive by separating the solids or otherwise.

We have shown in the Historical Notice (par. 54) that at the time the Act of 1858 was passed, giving power to the Metropolitan Board to design the main drainage works, it was understood that the sewage (if discharged at what were considered by many to be objectionable points) would, during some portion of the year at least, be treated by some process of deodorization before entering the Thames. That this might have to be done was clearly contemplated in the original scheme, and ministerial pledges were given in Parliament, in the name of the Metropolitan Board, that it should be done.

Probably the chief complaint against the Metropolitan Board is on this ground; but it must be borne in mind that this evil is not inherent in the system, but depends on its management; and the question how far it is remediable belongs more properly to the third head of our inquiry, which we propose to undertake hereafter.

81. There is still an important matter to consider in regard to the present system, namely—

THE DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER.

The quantity of sewage actually discharged into the river at the two outfalls of Barking and Crossness, has amounted, on the average of a few past years, to about 170 millions of gallons a day, or nearly 19,000 cubic feet per minute.

But this discharge varies exceedingly at different times, according to the quantity of rain carried off by the sewers; and it is generally admitted that the quantity of *sewage proper*, that is, the quantity which would flow off from the house and general drainage, without any accidental mixture of rain or spring water, may be fairly measured by the amount of the water supply. This is given in Mr. Baldwin Latham's table, Appendix R., and in the month of September it amounted to about 16,000 cubic feet per minute, or 144 millions of gallons per diem.

In dry weather the whole of this will enter the Thames at the two main outfalls, at Crossness and Barking.

In order to be able to judge of the consequences of this discharge from the great outfalls, it is desirable to consider what becomes of the sewage after it enters the river, and in what manner it may be distributed about by the various hydraulic currents or motions it encounters there. Accordingly this part of the question has received attention on frequent occasions, when the position of the outfalls has been under discussion.

82. The general nature of the problems involved under this head, may be simply explained as follows:

If a particle of sewage be discharged laterally into a flowing stream, not tidal, it is evident that (neglecting the effect of irregular currents) the particle will be carried downwards with a velocity depending on the quantity of water flowing, and the area of the section.

If, however, this particle of sewage be discharged into a tidal estuary, its motion becomes more complicated.

Suppose at first the case of a simple tidal creek, of considerable length, having no influx of fresh water at its head; the particle will acquire a reciprocating or oscillating motion, up and down the creek, with the influx and efflux of the tide.

If the particle be discharged at *high* water, it will descend the creek for a certain distance during the ebb, and when the tide returns it will be carried back again, about to the place it originally started from.

If it be discharged at *low* water, it will, in a similar manner, supposing the creek to be long enough, be carried up by the flood, and returned by the ebb to its starting place again.

If the particle be discharged at an intermediate point of the tidal motion, say, for example, at half ebb, it will first be carried downwards till low water, reaching a point situated at a certain distance below the point of discharge; it will then be carried up by the flood to another point situated at about the same distance *above* the point of discharge, and at half ebb it will have come back again to its first position.

At spring tides, this *tidal oscillation* will be longer than at neaps; and it will follow that during the transition from neap to spring tides, (since the quantity of water entering increases every tide,) the particle of sewage will be carried up a little higher every day.

Suppose now the sewage to be discharged into a tidal estuary, which receives the fresh water of a river at its upper end, as in the River Thames. The discharged sewage will undergo a daily oscillating motion, due to the tide, but it will also be subject to a gradual progress down the river, due to the constant accession of upland water at the head and sides of the estuary, which must ultimately find its way down to the sea. In other words, the tidal oscillation will still continue; but its locality will suffer a gradual movement or *displacement* down stream, the amount of which will be dependent on the quantity of fresh water entering the river.

Another effect follows from the tidal oscillation. Supposing the sewage to be discharged during certain portions of every tide, the effect must necessarily be that the discharge of one day will, to a large extent, mix with the discharges of previous days, and so there will result an *accumulation* of sewage in the oscillation space. The amount of this accumulation will depend on the rate of downward displacement. When little land water is entering, the displacement will be slow, and there may be many days'

accumulation; while in time of land floods the downward progress will be rapid, and the accumulation will be reduced.

The above considerations assume the motions of the water in the river to be regular and simple; but in practice they are not so. They are subject to many irregularities and complications of various kinds, which produce a peculiar effect called the *mixing action*. This is of considerable importance, as influencing materially the distribution of the sewage, and it will be more fully described hereafter.

All the points embodied in the foregoing general statement have been discussed at various times, and a great body of information on them has been laid before this Commission. The Corporation of the City of London have, especially, undertaken a very elaborate series of investigations, for the purpose of illustrating this subject. They will be found described in the evidence of the scientific witnesses, and they throw considerable light on all the points named under this branch of the inquiry; namely, the tidal oscillation, the gradual progression downwards by displacement, and the mixing action.

83. First, as to the tidal oscillation. When Mr. Frank Forster was making his early designs in 1850–1, in order to judge as to the position of his outfalls, he directed some experiments to be made to ascertain the nature of the tidal currents in the river. These experiments were carried out by Mr. Phillips, who has described them in his evidence. (Q. 6357, *et seq.*)

Floats were put into the river at Barking Creek (the proposed point of outfall) at different times of tide, and their positions noted at the extremes of their motion. The general result was to show, first, that the tidal oscillation varied from about 10 to 14 miles in length; secondly, that when the float started from Barking after high water, it was carried by the next flood tide considerably above Barking; and thirdly, that the permanent progression down stream did not exceed five miles in 15 days, *i.e.*, on the average, one third of a mile per diem. As a deduction from the experiments it was stated,—

"That if the sewage be not put into the Thames at Barking Creek at some period earlier than two hours after high water each tide there will always be the certainty of its going up the river as far as Greenwich; and should a long continuation of northerly winds happen just after the times of lowest neaps, there is every probability of its being drawn up as far as Rotherhithe."

Sir Joseph Bazalgette, in his evidence before this Commission, refers to these tidal experiments. He gives (Q. 5) 12 miles as the extent of the tidal oscillation; and he says (Q. 86), "it may be roughly assumed that a substance in suspension works up the "river about one mile a day at each high water as the springs strengthen, and down "the river two miles a day as they fall off." But he does not consider that the motion of a float is analogous to what would take place with the particles of sewage.

Five years later these experiments were checked, at the request of the First Commissioner of Works, by Captain Burstal, who has given the Commission an account of his experiments and his report upon them. (Q. 6485 to 6500, and Appendices C. and L.) He confirmed the accuracy of Mr. Frank Forster's experiments, and added some data as to the set and velocity of the streams and currents in that part of the river, showing that certain circumstances connected with them were favourable to the deposit of matters in suspension.

Captain Burstal also adds (Q. 6427 and 6500) further experiments on the set of the tides.

In 1857 the Government Referees, Messrs. Galton, Simpson, and Blackwell, referred to the experiments of Mr. Frank Forster and Captain Burstal, and to some further float trials made by Mr. Homfray. The conclusions they drew on the subject have been given in the Historical Notice.

A large series of float experiments, made expressly for production before this Commission, are described in the evidence of Messrs. Baldwin Latham and Birch, and graphically delineated in the drawings Appendix T. A special description is also given in Mr. Latham's Report, Appendix R.

Seven distinct sets of observations were made, with large floats specially constructed for the purpose. These floats were put into the river, opposite the northern outfall, at various periods of the tide, and each float was carefully watched and its motions and positions were accurately recorded for many days; some were observed for 45 days, others for more than 30 days, and one for 18 days, all therefore giving a range over both springs and neaps.

There are many anomalous circumstances in the recorded motion of the floats, arising probably from wind, or irregularities in the currents, or other accidental causes; but there is not a doubt of their good faith, and as a whole they bear evidence of trustworthiness, and may be considered as representing what they profess to represent, namely, the actual motion of some portions of the water of the river, in the neighbourhood of the northern outfall, under different tidal conditions. And the rough practical inference may be undoubtedly drawn from the experiments, that where the floats went, sewage discharged from the northern outfall, at the same times of the tide, may also go.

The chief points shown by these experiments are briefly as follows:

1. The extent of the tidal oscillation varied considerably; the variation being due, not only to the character of the tide, but also probably to the position any particular float happened to occupy in the river, some parts of which move faster than others.

2. The maximum range of oscillation recorded, at spring tides, was about 18 miles, the minimum, at neap tides, a little under seven miles; the mean of the whole of the observations gave about 12½ miles.

3. A float which was started from the northern outfall at high water, is said to have ascended, with subsequent flowing tides, to a distance of seven or eight miles *above* the outfall, or to Greenwich.

4. Another float which was started from the northern outfall three hours after high water is said to have ascended, with subsequent flowing tides, to a distance of 20 miles above, or between Putney and Hammersmith bridges.

5. Another float which was started from the northern outfall at low water, is said to have ascended, with subsequent flowing tides, to a distance of 21 or 22 miles above, or between Hammersmith and Chiswick.

The general results of these experiments accord fairly with those formerly obtained, so far as the length of the daily tidal oscillation is concerned, and they add important and novel information as to the distance to which the tidal currents may travel. For it is now evident that, at whatever time of tide the sewage is discharged, some of it may, under certain conditions, be carried up by the tidal oscillation alone into the heart of the metropolis, and even further.

84. The circumstances of the discharge at the metropolitan outfalls are as follows:

The sewage is received into reservoirs having sluices communicating with the river. These sluices are intended to be opened at high water, and to remain open until the quantity accumulated is discharged. The discharge at present takes some three or four hours, but it is sometimes necessary to let out the sewage even during the rising tide. It is admitted that the storage room is inadequate, and the Metropolitan Board are preparing to increase it considerably.

Supposing, however, that the discharge can hereafter be confined to two or three hours after high water, it is obvious that on the return of the tide, the oscillation will still carry a portion of the discharge above the outfalls; for by the time the latter part of the sewage has returned to the place of its discharge, the flowing tide will still have some hours to ascend, and must therefore carry the sewage with it.

Moreover, during the transition from neap to spring tides, the tidal oscillation will increase in length, and consequently the sewage, however discharged, will make its way daily further and further above the outfalls.

It must also be remarked that, if the time of discharge be reduced, the pollution of the river at or near the outfalls will be proportionally augmented during such time. And as the volume cast into the river increases, this evil will obviously increase also.

85. The float experiments give no trustworthy information as to the gradual *displacement*, or progress downwards, of the sewage by the constant influx of fresh water. There has been an impression that float experiments ought to show this, but the resulting movement is so small that it is lost in the numerous irregularities to which the floats are subject in their travel. Hence the data for determining this quantity must be sought elsewhere.

An estimate of it may easily be made by calculation; for, assuming the mass of water at any given place to be pushed bodily downwards by the influx of fresh water above, the mean displacement will be equal to the quantity of the inflow, divided by the area of the section.

Taking therefore the area of section at the outfalls, at mean tide level, at about 50,000 square feet, we have, in order to find the mean displacement due to any influx, to divide the quantity inflowing by this number.

It need hardly be said that the quantity of upland water inflowing varies enormously at different times. The *mean* quantity, above the outfalls, over an average year, may be taken at about 120,000 cubic feet per minute, which would give a displacement near the outfalls of about 2·4 feet per minute, or $\frac{2}{3}$ of a mile a day.

But in heavy floods the influx reaches about 1,500,000 cubic feet per minute, which would give $8\frac{1}{4}$ miles a day.

On the other hand, in dry seasons, the inflow diminishes to about 48,500 cubic feet per minute, which would give a displacement of only a little over $\frac{1}{4}$ a mile a day.

Mr. Frank Forster's experiments, previously quoted, give an average of one third of a mile per day; Sir Joseph Bazalgette appears to have estimated about half a mile.

As the sewage descends the river, its progress will become slower and slower. In mean seasons it would require, on the whole, about 150 days to travel from the outfalls to the sea, if its progress depended on the influx of upland water alone.

·86. It is now, however, necessary to describe, more at length, the peculiar feature already briefly alluded to, namely, the *mixing* action, which has such a remarkable influence on the distribution of the sewage in the river.

When, after low water at the mouth, the tide enters from the sea, a quantity of salt water will of course find its way for a certain distance up the river; but there is no sharp line of demarcation between the salt water that has so entered, and the fresh water that travels down the stream. The change is very gradual, and extends over a long distance. The saltness diminishes as the river is ascended. At the mouth it is somewhat less than that of the sea. Higher up the water becomes brackish, and then gradually passes to the state of fresh water. But the saltness, in some degree, extends to a distance very far beyond that which the sea water would be supposed to travel on purely hydraulic considerations. In the Thames, for example, it is well known that the water is perceptibly brackish a long way above Gravesend, and the presence of sea water can be traced not only through London but occasionally almost up to the tidal limit at Teddington.

This effect is due to a singular process of mixing which goes on between the fresh and the salt water during the tidal movements. There are many causes which contribute to this effect. In the first place, the velocities of the water vary much in different parts of the same section of the river; secondly, the regularity of the currents is largely interfered with by the configurations of the shores and the bed, producing eddies, patches of slack water, reversals of the current, and so on; thirdly, other irregularities are due to the agitation caused by strong winds; fourthly, the sea water, the land water, and the sewage are all of different specific gravities, and consequently tend to occupy different levels; and fifthly, there is a tendency in fluids to mix or diffuse, when brought even into simple contact with each other. All these causes combine to produce a mixing of the sea and land water, to a much greater extent than has hitherto been supposed.

87. The proof of the mixing action, and at the same time the means of its quantitative determination, are furnished by the amount of *chlorine* found in the water; and the scientific witnesses engaged by the Corporation of London have brought this consideration forward very prominently, as a means of throwing light on the distribution of the sewage in the Thames.*

It is argued, and we think correctly, that since a mixing action is known to go on between the sea water and the land water, there is every reason to believe that the same kind of action will go on between each of these and the sewage; and that the chlorine test ought to afford a means of determining the extent of this mixing action, so far as the sewage is concerned.

For example, the chlorine test shows that in the water at Chiswick, at certain times, a quantity of chlorine is found which cannot be traced to any source except the sea; proving, therefore, that by the mixing action some sea water from Southend has ascended to that remote part of the river. But since, in travelling there, it must have passed through the fluid mixture distributed near the outfall, it must have brought with it a portion of the sewer discharge, and hence an extent of distribution is proved which has never been suspected heretofore.

The data for the statements laid before the Commission are derived from the determinations, by Professor Way (since deceased) of the amounts of chlorine contained

* See also the earlier report to the Woolwich Local Board by Mr. Wigner, F.C.S., as to the flow upwards of sea water along the bottom of the river. Appendix O.

in certain samples of water (see Q. 11,286 *et seq.*) taken on certain days at various points of the Thames, from Teddington to Southend. To these are added (see Appendix R.) the known quantities of land water and of sewage entering the river on each of the days in question.

The problem then, is, having given the quantities of chlorine contained in sea water, land water, and sewage respectively, to find the proportion of each in the sample analysed by Professor Way.

This has been solved by Mr. Baldwin Latham, by Mr. Mansergh, by Mr. Birch, by Professor Unwin, by Dr. Frankland, and by Professor Way, each using an independent method; and another independent mode of calculation has been given by the Secretary to the Commission in Appendix A.F. The results are fairly concordant.

Objections have been made both to the data and the calculations founded on them, but we are satisfied that the results throw quite a new light on the distribution of the sewage.

It is now clear that the notion that, by certain arrangements at the outfalls, the sewage there discharged may be made at once to descend the river, and so get away, must be abandoned. For not only is a certain travel up the river produced by the tidal oscillation, but, by the still more comprehensive and extended nature of the mixing action, part of what is discharged from the main outfalls is carried upwards, under certain circumstances, over almost the whole tidal range.

Nobody has hitherto anticipated that liquid discharged into the river at Barking could be transported, by any natural causes, many miles up the river, directly in the face of the powerful descending stream of the land water; but that this effect is produced can no longer be doubted.

We notice, however, that, as might reasonably be expected, the penetration of the sewage liquid upwards is influenced considerably by the strength of the land stream. When the quantity of land water is large the upward travel is much less than when little land water is coming down.

We consider it also proved, by the calculations based on the chlorine test, that the proportion of the sewer-liquid contained in the river in the neighbourhood of the outfalls is, in dry seasons, very large. Some of the calculations profess to show that, in the driest weather, this proportion may possibly approach one-sixth of the whole volume of the river; but we may make a large deduction from this, and still find a startling result.

88. Some misapprehension has often existed as to the extent of the *dilution* of the sewage by its admission into a bulk of water in the river. It is asserted, with truth, that the quantity of water passing the outfalls during the time the sewage is being discharged is some hundreds of times greater than the quantity of sewage it receives, and hence it is argued that the sewage must be diluted to this amount. But this is a fallacy, inasmuch as the water so passing is not pure water; it is water which, by the tidal oscillation, has already become contaminated by the *accumulation* before mentioned, of successive previous sewage discharges. The only true sources of dilution for the sewage are the land water entering above and near the outfalls, and the salt water which finds its way upwards from the sea. It is very difficult to estimate the effect of the latter, as we cannot tell how often it may be changed; but the benefit of the dilution by it is diminished by the fact that the sea water, in its passage up the river, has to meet and mix with the sewage mixture travelling down, which must (except in so far as the sewage has undergone oxidation) contaminate it and diminish its purifying capability.

It is asserted on behalf of the Metropolitan Board that there may be another element of dilution, namely, spring water which may find its way into the bed of the river from the permeable strata around. There appears, however, to be no satisfactory evidence of such accession of any considerable quantity of land water to the river. No doubt the permeable strata in the London basin contain a large store of water collected from the rain falling on the land surface above them; but there is reason to believe that these stores are so drawn upon in the neighbourhood of the river, as to bring the subterranean water level below that of the Thames, which would effectually prevent the spontaneous flow into the river that is relied on by the Metropolitan Board.

89. It has been shown that the mixing action considerably facilitates the permanent progress of the sewage out of the river. Instead of the two-thirds of a mile dis-

placement near the outfalls due to the fresh water alone, in the mean conditions, the mixing action may be stated to produce a permanent displacement of eight-tenths of a mile per day. In dry weather, the sewage discharged at the outfalls gets out to sea, after about 30 days oscillation up and down. It may thus be said that by this natural process of mixing, the sea sends, so to speak, an auxiliary carrier up to the high parts of the estuary to help the land water in bringing the sewage down.

90. There is one respect in which the mixing action is less beneficial, namely, that the combination of sewage with sea water produces less inoffensive compounds than with fresh water. The calculations show that in dry weather at high water (when the sewage is discharged) there is a large proportion of sea water in the river; and it is clear, therefore, that the discharge of sewage into such a mixture must be liable to produce a greater nuisance than if running into a fresh stream.

91. But while we consider that the wide distribution of the discharge from the sewers, and its occasional large proportion in the river, are sufficiently proved, we think that the answer which the Metropolitan Board have put forward to the objections these facts raise to their system is worthy of attention.

They say that the sewage, during its oscillation, travel, and mixing, becomes so quickly oxidised and purified as to lose, almost immediately, all its offensive qualities, and to become as innocuous as the natural water in the river; for which reason these elaborate discussions of the distribution of the sewage have no practical importance.

We shall consider the validity and force of this argument in the following part of our report.

# PART III.

92. We now proceed to the main object of this Report, namely, the consideration—

## WHETHER ANY EVILS RESULT FROM THE SYSTEM UNDER WHICH SEWAGE IS DISCHARGED INTO THE THAMES BY THE METROPOLITAN BOARD OF WORKS.

Five evils have been mentioned as arising, or likely to arise, from this discharge, namely—

(A.) Injury to the Healthiness of the Districts in the Neighbourhood of the River.

(B.) General Nuisance and Inconvenience from the Pollution of the River.

(C.) Injury to Fish.

(D.) Pollution of Wells near the River.

(E.) The Formation of Shoals or Banks which might prejudice the Navigation of the River.

We will deal with each of these in order.

---

### (A.)

### Injury to the Healthiness of the Districts in the Neighbourhood of the River.

93. In many of the complaints, a fear has been expressed that the discharge of the sewage has had, or may have, a serious effect on the health of the populations on the banks of the river.

94. We have received much evidence on this point. In addition to general witnesses, we have heard, on the complainants' side,

Mr. Jesset, Medical Officer of Health for the Urban District of Erith.
Dr. Collingridge, Medical Officer of Health to the Port of London Sanitary Authority.
Dr. Corfield, Professor of Hygiene at University College.
And Dr. Browning, Medical Officer of Health for Rotherhithe.

On the respondents' side.

Dr. Maxwell, Medical Practitioner at Woolwich.
Mr. Coleman ,, ,,
Dr. Lett ,, ,,
Dr. Wise ,, at Crossness.
Dr. Dixon, Medical Officer of Health for Bermondsey.
Mr. F. M. Corner, Medical Officer of Health for Poplar.
Mr. Tatham, Medical Practitioner on the river.
Mr. Mason ,, at North Woolwich.
Dr. Rowarth, Medical Officer of the "Exmouth."
Dr. Tripe, President of the Society of Medical Officers of Health.
Surgeon Major Griffith, in medical charge of the magazine at Purfleet.
Dr. Dickson, Medical Inspector to Her Majesty's Customs.

Professor Corfield has put in some tables which he considers show that the death rate from zymotic diseases is higher in the immediate neighbourhood of the river, the foul condition of which he considers may have contributed to this result.

But his conclusions are called in question, and do not appear to be supported, while the testimony of the respondents' witnesses unanimously asserts that no such deterioration of health can be perceived.

95. We cannot see sufficient evidence to show that, hitherto, the sewage discharge has produced any serious injury to health, either among those who live in the vicinity of the river, or those who live partially or wholly on the water in the neighbourhood of the outfalls.

96. But there is abundant evidence of its having produced affections of a slighter kind, as the following extracts will show:

*Beadle*, 262.—I have had constant complaints from my men as to illness resulting from the smell. In hot weather I cannot stand it; it produces a headache and makes me feel sick. We have had more men laid up in the last three years than ever before. In hot weather the men can scarcely stand it.

*Egerton* (*Erith, Surveyor*), 979.—My family have suffered illness from the smells arising from the river. Several physicians advised me to take my family away from the river, which I have done, seven or eight years ago.

*Savery* (*Custom House Officer*), 1460.—Diarrhœa on board vessels which he supervised.

*Sibley*, 2116.—Five or six of us have had to knock off work, and we have felt very queer.

*Lee*, 2279.—Often have the headache, and am sick from it in summer. Does not agree with my wife and daughter.

*Harling*, 2547.—I am under the doctor's hands from it now. Every time I go into the dock I am forced to go to him.

*Clarke*, 2607.—Nasty faint sickness.

*Roberts*, 2845.—Very sick at times. Man suffered from diarrhœa.

*Mastin* (*Policeman*), 3099.—I have had to go out of the boat on account of the smell, and felt very sick; and had to vomit once or twice.

*Capt. Lynch*, 3306.—Have known men to be sick from the smell.

*Capt. Hussey*, 3511.—My family have suffered, they were taken ill in the summer time.

*Fuller*, 3668.—For two summers I was very poorly with sickness.

*Edmunds*, 3976.—Ill with loss of appetite and faintness.

*Saunders*, 4046.—Several men laid up.

*Jesset*, 4434. — I have had occasion to treat persons for illness caused by this matter. Could name several cases. In one case a new man on the Thames Police yacht had not been on board above a week before he was seized with most violent diarrhœa and sickness; when removed, he got well. Number of men working in the mud and at the ballast wharf have suffered in the same way. A fair number of cases. Ladies on a yacht were sick, and could not take their tea on account of the atrocious smell.

*Rev. J. McAlister* (*Vicar of St. Nicholas, Plumstead*), 4817.—At certain seasons when these foul odours came over the parish, I have noticed that the effect produced upon the health of the inhabitants is much the same as the effect that a hot wind would have on vegetable life if it were blown over vegetable life, under certain conditions, *i.e.*, the *vis vitæ* sinks directly; and you find that the inhabitants, as a rule, myself included, feel it. I am as healthy a man perhaps as you would find anywhere, but I feel it as others do; that the vitality is not so powerful in the animal system as it is at other times. That is more the case than it used to be.

*Capt. James* (*Harbour Master*), 5807.—I have frequently been made quite ill with the smell, going up and down, so that I have not been able to eat my dinner when I have got home.

*Dr. Collingridge*, 5914.—I have frequently, in hot weather, been very seriously inconvenienced indeed. I have had distinct nausea, and, in bad cases, actual vomiting. I frequently get diarrhœa when I have been on the water in hot weather, for any length of time. I can, undoubtedly, attribute these symptoms to the state of the river.

*Long*, 5936.—Men on board the "Conservator" felt sick.

*Turnidge*, 6096.—I have felt very sick indeed at times: on one occasion I was obliged to give over altogether; I was absent from work.

*Custance*, 12,465.—The river has given great headache and diarrhœa to him and other men.

97. The above evidence shows that the sewage discharge does occasionally produce inconvenience, temporary indisposition, and a low state of vitality, the cause of which ought not to remain if reasonable means can be found for its removal. This result, however, is limited to those who are either actually upon the river, or on its margin; for we have strong and trustworthy evidence that the smell is not perceived a short distance from the river.

The constant presence of a large mass of water, containing a vast quantity of crude sewage, constitutes a danger to public health, which demands attention, more especially as the evil must increase with the growth of population.

---

## (B.)

### General Nuisance and Inconvenience from the Pollution of the River.

98. In a former part of this Report, we have described the wide ultimate distribution, both up and down the river, of the discharge from the main sewage outfalls.

But with reference to the probable nuisance, it will be well to direct attention to the circumstances of the actual discharge from the outfalls, and to what takes place in their more immediate neighbourhood.

99. The volume of sewage discharged each tide is enormous.

Taking, as before stated, the average volume of sewage proper over the 24 hours to be 16,000 cubic feet per minute, and supposing it to be discharged during three hours every tide, there will, for those three hours, flow out a stream of about 64,000 cubic feet per minute; so that a mass of about $11\frac{1}{2}$ millions of cubic feet of concentrated sewage will enter the river in the three hours.

The stream of sewage flows out at Crossness under the surface of the water in the river. At Barking it discharges at a higher level and part of the time not under water; but in both cases it immediately becomes appreciable, and continues (as is usual where one stream joins another) unmixed for a considerable distance. It is allowed on all hands that this sewage stream, so long as it retains its separate character, is very offensive in its immediate neighbourhood.

After a time, the sewage stream begins to mix with the water of the river, and the mixture becomes less offensive. The solid matter, to which, more than to the fluid, we attribute the origin, proximately or remotely, of the offensive smells, decomposes; the noxious gases which result are dissolved in the water, and when the water is stirred up, they escape into the air. This agitation is effected by the passage of steamers, and as the traffic is very great, the effect is kept up for a considerable distance from the outfalls both up and down the river. Within this range the water is in such a foul state as not to be usable, even for such purposes as washing ships' decks, &c.

After a further time, and a more extended travel of the sewage discharge, the mixture with the river water becomes more complete, and a change takes place, on which great stress is laid on by the Metropolitan Board. They assert that, by the dilution with the river water, and by the constant agitation due to the tidal oscillation and other motions, a process of natural purification by oxidation sets in, which, in time, deprives the discharged fluid of its offensive properties, and causes it to become more like the natural water in the river.

This is admitted by the complainants, the only question being, how soon the purification becomes effective, and whether, in the meantime, nuisance is caused.

The limits of distance, above and below the outfalls, where this purification becomes effective in preventing nuisance are very indeterminate, varying much, at different periods, according to the supply of water to the river, and the temperature.

We may, however, state that there has been no evidence to lead us to believe that any substantial nuisance attributable to the metropolitan sewage is complained of above Greenwich, or below Greenhithe.

In regard, however, to the part of the river lying *between* these limits, it is complained that the effects of the sewage discharge are distinctly appreciable. The Metropolitan Board admit that some nuisance exists, and must, under the present system always exist, in the immediate neighbourhood of the outfalls; whilst the complainants assert that, in hot and dry weather, this nuisance becomes very considerable, and extends some distance both up and down the river, the question being one of degree.

There is also a further cause of complaint, namely, the deposit, in the neighbourhood of the outfalls, of a certain kind of mud, which when exposed at low water on the banks, or brought up by the dipping into it of ships' anchors, chains, nets, &c., is exceedingly offensive, and betrays sewage origin.

100. It is now our duty to state the general nature of the evidence we have received on this part of the case; and as this is, we conceive, the turning point of our whole inquiry, we feel it necessary to go into the matter in some detail.

The evidence is of two kinds, *popular* and *scientific*.

*Popular Evidence.*

101. Before discussing this, it is right to mention the complaints made before this Commission was appointed.

The complaint from Barking in 1868, which we have already mentioned, alleged the pollution of the river, and the allegation was confirmed in Mr. Rawlinson's Report.

In October 1878, shortly after the lamentable loss of life by the sinking of the "Princess Alice" steamboat, near the Barking outfall, the Woolwich Local Board directed their surveyor to take samples of the water in the Thames, in and about the spot where the accident occurred, and to have them analysed. This proceeding had special reference to the question whether the water was so contaminated by sewage discharge as to cause the death of any of the passengers in the unfortunate vessel.

The reports of the surveyor and of the analyst are printed in Appendix O., and the latter contains the following passages:

I think the various facts afford the most conclusive ground on which to base an opinion that the whole of the river from Billingsgate to Jenningtree Point was, on the 14th of October last, greatly contaminated with sewage, and that, subject to certain irregularities which may be due to local circumstances in the river, this contamination increased as we passed down, and that on the whole the greatest contamination was found in the samples taken at the wreck and half-way between the two outfalls.

In Appendix N. we give copies of a series of documents transmitted to us by the Thames Conservancy Board. They consist of various complaints made to them during some years before the appointment of this Commission. We add a few extracts. The Harbour Masters say, at various times—

16th July 1880. The river water every day and night has been heavily charged with sewage; the odour, even as far as Blackwall, is worse than I have known it. The water last Monday at nearly half flood was so bad that I landed at the southern outfall to ascertain if the sluices were not open. The foreman assured me they were closed.

The nuisance still continues to be felt, and is spoken of on all sides.

25th July 1880. Since my last report, the water has become much worse, and it is now so heavily charged with sewage matter that it cannot be used for the decks, or even in the cisterns, and has become a public nuisance.

Throughout the whole of my district (from Greenwich to Greenhithe) the water has been foul, and from Erith upwards the water is crowded with sewage at all times of tide.

The stream between Halfway Reach and Woolwich is nearly black at half tide, both on the flood and ebb, and I have no hesitation in describing it as little better than an open sewer in this part of the river. At the top of high water sewage is present in all directions, which is quite a new feature in my experience.

It is my opinion that the present filthy state of the river calls for the immediate attention of the port sanitary authorities.

26th July. The river on the flood tide on the 24th inst. was in a very bad state, the water black and full of filthy black looking matter in suspension, and giving forth a most disagreeable smell. At Millwall it got worse, and off Port of London Wharf and as far as East Greenwich at three-quarter flood the odour was horrible and sickening. The effect was felt by all the crew of my boat.

5th July 1881. The water of the river is this day very offensive on the ebb, more particularly so at high water this morning.

14th July 1881. Water very dark, discoloured, and offensive this day towards high water.

20th July 1881. River during the past week in a very filthy state. Between Purfleet and Charlton more especially it is heavily charged with sewage matter visible at all times of the tide, and its sickly odour pervades every part of the district.

See also a long series of extracts from the Harbour Master's Journal (central station) extending from the 20th December 1878 to the 21st August 1881.

Captain Gillett, R.N., captain of the "Warspite," lying off Woolwich, writes, 27th July 1880—

I think it my duty to report the bad state of the river where this ship is lying. It is no exaggeration to say that for several days past the whole river has been neither more nor less than an open sewer, the water of a dark slate colour, and large masses of solid sewage floating past.

Mr. W. Woolcott of the Trinity House, says, 21st July 1881—

I beg to call your attention to the filthy state of the river between Blackwall and Tripcock Point. I slept on board the "Galatea" on Sunday night last, and was obliged to close the scuttle owing to the smell of the water passing the paddles. The water was quite black. Everybody I met was complaining bitterly about the state of the river.

The Secretary of the London Steamboat Company writes, 25th July 1881—

We have lately had so many complaints from our captains, as well as from passengers by our steamboats, that we now send you from our lessees a formal complaint setting forth the facts referred to in language unmistakeable.

The General Manager and Secretary of the Thames and Channel Steamship Company notes, on the same day—

The filthy state of the river below bridge, more particularly about Woolwich. The effluvia thrown off by the sewage floating up and down in the stream is positively poisonous, the river being for miles black with it. As an instance, yesterday morning at 10 o'clock the passengers on board the "Eclair," at Woolwich, were seriously annoyed; the smell was almost unbearable.

The Local Government Board transmit a Resolution dated 20th September 1881, received from the Vestry of Plumstead, stating that their attention had been further drawn to the alleged nuisance by an influential and representative deputation from the locality. The Resolution states—

That this Vestry expresses its abhorrence at the continued impurities from sewage existing in the Thames near the metropolis, contrary to the 135th section of the Metropolis Local Management Act, 1855; and that this resolution be forwarded to the Local Government Board with an earnest hope that it will concert measures to remedy the evil complained of.

The Conservancy Board give extracts from their own annual report for 1880, which contains the following passage:

During hot weather, when there has been little rainfall, complaints of the pollution of the river within and below the metropolitan district frequently reach the Conservators. The pollution thus complained of is indicated by the offensive odour and highly discoloured state of the water.

In Appendix A. J. we have printed some of the annual reports to the Erith Local Board, from their medical officer, Mr. Jessett. In the two dated 29th January 1879, and the 22nd January 1880, he alludes briefly to the deposit of sewage on the river banks near that town. In a subsequent one, dated January 25th, 1882, occur the following passages:

I was most pleased to see that your Board fully entered into the vital importance of endeavouring to force the Metropolitan Board to do something to abate the abominable nuisance they are causing by pumping the enormous amount of sewage into the river at Crossness and Barking.

There are few among you who do not remember the vile stench emitted from the mud on our shore at low tide during the excessive heat of last summer. Without exception I will venture to assert all the yachtsmen who lay off our town will agree as to the filthy masses of black sewage washed backwards and forwards by their yachts during that excessive heat, and of the stench emitted from the river generally. It was a source of some surprise to me that fever of the most virulent type was not manifest among the crews of the yachts.

In October 1881, the Common Council of the City of London instructed the Port Sanitary Committee to inquire into the sanitary condition of the River Thames in the neighbourhood of the outfalls. They reported on the 14th December of that year, and we give a copy of their report in Appendix P. The essence of it is as follows—

In the minds of your committee there can be no doubt that the action of the Metropolitan Board of Works in taking the sewage of the metropolis down the river to Crossness and Barking Creek, has materially benefited that part of the Thames immediately adjacent to London; but equally without doubt the state of the river at these points, although, being greatly affected by meteorological changes, it must of necessity vary from time to time, is, in consequence of the great outpouring of sewage, always in a condition most unsanitary, and that in hot weather, in times of drought and great heat, its very prejudicial effect upon the public health is obvious. And bearing in mind the fact that the quantity of sewage has of late years enormously increased, and is constantly increasing, your committee feel that the time has arrived when some definite action should be taken in the matter.

This opinion is confirmed in a subsequent report, dated 16th March 1882.

In March 1882 a number of gentlemen in the City, interested in the traffic on the Lower Thames, held a meeting, at which a resolution was passed—

That, in the opinion of this committee, a Royal Commission should be appointed, or a parliamentary inquiry instituted, for the investigation of the present state of pollution of the River Thames from sewage, and the means to be taken to remedy this alarming and growing evil.

An executive committee was formed, and in the month of April a memorial on the subject was presented to the Right Hon. W. E. Gladstone. A copy of this is printed in Appendix K. It was entitled—

*The* MEMORIAL *of the principal merchants, traders, and shipowners, and the representatives of the dock, wharf, and shipping interests on the River Thames, the owners of barges and the steam vessels engaged in the passenger traffic of that river, associated together, and forming a general committee for the protection of the Lower Thames from sewage.*

It recited a petition, signed by above 13,000 persons, of many different classes in life, that had been presented to Parliament in the previous session, and it contained the following statements:

That the Metropolis Local Management Act, 1858, which authorises the discharge of the metropolitan sewage at Barking and Crossness, was passed, as your memorialists are informed, under the belief, "First, "that the sewage discharged would not increase to the enormous extent it has done; secondly, that the sewage "would be deodorized before its discharge into the river; and thirdly, that the action of the tide in the river "would have the effect of carrying the sewage water or matter into the sea, instead of its remaining in the "river, as is now the case, and being carried up and down between Gravesend and Blackwall, or points higher "up the stream."

That, although the 23rd section of that Act (for deodorizing the sewage) may be construed as having application only to the period during which the works under the Act were in course of construction, the spirit and contention of the 24th section (forbidding any nuisance) is obviously to prevent the nuisance now complained of, although, according to the legal construction of the words of the said section, it does not supply the means of enforcing such intention.

The memorial prayed the appointment of a Royal Commission to inquire into the matter.

It was signed on behalf of the memorialists by Professor J. E. Thorold Rogers, M.P. for Southwark, and there was appended a list of the committee, 159 in number, among whom were many gentlemen and firms of high character and position.

Early in 1882 the town clerk of the corporation of the City of London wrote to the Home Secretary a letter,* as follows:—

SIR, Guildhall, E.C., 19th January 1882.

THE question of the pollution of the River Thames by sewage from the outfalls at Crossness and other places has recently been the subject of serious consideration by the Port of London Sanitary Committee of the Corporation; and, guided by personal inspection and the results of a careful chemical analysis of the water of the river in the localities in question, they find that without doubt the state of the river at Crossness and Barking Creek (although in consequence of constant meteorological changes it must of necessity vary from

* The correspondence here mentioned is printed in Appendix J.

time to time) is, from the great outpouring of sewage, always in a condition most unsanitary, exercising, in periods of drought and great heat, very prejudicial effects upon the public health; and, bearing in mind the fact that the quantity of sewage has of late years enormously increased and is constantly increasing, the Committee feel that the time has arrived when some decisive action should be taken in the matter, and they therefore deem it expedient to take the step which, under the Metropolis Local Management Act, 1858, cap. 104. sec. 31, is open for adoption, and I am therefore instructed to urge upon you the extreme importance of immediate steps being taken towards remedying that which must be admitted to be a great and growing evil.

I have, &c.

(Signed) JOHN B. MONCKTON.

About the same time applications of a similar character were made by the Woolwich Local Board.

The Local Board of Plumstead also applied to the Local Government Board, who transmitted the complaint on to the Home Office.

The complaints were referred to the Metropolitan Board, who denied the allegations made. The Home Secretary then, in a letter dated 25th May 1882, declared his intention of causing an inquiry to be made, and the result was the issue of your Majesty's Warrant appointing the present Commission.

102. We may now refer to the popular evidence, from direct observation, taken on our own inquiry.

Evidence of this kind has been given, on behalf of the complainants, by a very large number of witnesses, of different ranks in life.

103. First as to the *General Foul State of the Water*. The following are abbreviated extracts from the statements made, using generally the actual words of the witnesses.

The references are only to the earlier numbers of the questions. It will be easy to identify the succeeding portions.

*Beadle*, 236.—The river has been growing gradually more dirty and more objectionable. It is getting worse every year. In hot weather there is a very disagreeable smell, particularly in the last few years. Coming up the river, it begins to get thick in the Lower Hope, it gradually gets worse till you reach the outfalls, which is the worst place, then it begins to get better again till you get up to Greenwich, and before you come to London Bridge you come to very decent water again. The worst part is from Blackwall to Greenhithe. The water turns black and gives off a gas from bubbles with a disagreeable smell, a sewage smell. In hot weather I cannot stand it.

*Busby* (*Pilot*), 446.—These last four or five years, to come up on board of a ship with a tug towing ahead of you to stir the water up, is dreadful. From Erith to Woolwich is, I consider, the most obnoxious and the largest cesspool in the world. I often hold my handkerchief to my nose for an hour together. The men do not clean the decks as they used to do, on account of the water being so filthy and black as ink; the mate has knocked them off, and let them begin again in Long Reach. The obnoxious stuff, unless it is a very hot summer, has not come into Long Reach yet. The sewage water would come up as far as Greenwich, or even further. You would see just at high water a large circle from the outlet right over to the other side and extending a mile, black as ink. The Members of Parliament got it in 1859, and we get it now. If everything is still and quiet, it is something frightful on hot summer mornings.

*Sandford* (*Pilot*), 547.—Since the outfall was opened, it has gradually got so bad, and now it is as bad as the upper part was before. It has been gradually getting worse the last eight or nine years. We get worse water round Maggotness; the "Stink Factory" we call it in Jenningtree Reach. We used to make our best effort to watch the time, to get clear of the stench. We would lose an hour to clear it.

*Capt. Morrel, R.N.*, 660.—I consider the river near Erith very much impurer of recent years. I have discontinued washing the decks several years, because the water used to smell so badly that it was unhealthy; a sickening smell arising from gases.

*Capt. Walter, R.N.*, 731.—In my opinion the state of the river has been worse during the last eight years. There is a smell from the water in hot weather and at low tide.

*Capt. Gillet, R.N.*, 804.—For a month in the middle of the summer, generally in July, it has been very bad; the water becomes slate coloured, and great masses of black mud come up from the bottom and spread all over the surface. It has been very bad indeed. The smell is perfectly dreadful. I am obliged at night time to close all the ports and keep the deck under the hammocks wet with disinfectants. We do not use the water in summer for washing the upper deck or washing the boys. One of the mooring chains when lifted was all covered with sewage. When the river gets slate colour, which it does in the summer, the oars and the blades all turn black. The sewage comes up to Woolwich. The whole bed of the river, I believe, is covered with it 20 inches, and when the temperature rises to a certain point, it rises with it. It appears as if gases exploded in the bed of the river, because it comes up and spreads all over. It comes up in great masses of black stuff, sometimes as big as this room.

*Egerton* (*Surveyor, of Erith*), 913.—I have noticed a very great alteration in the state of the river since the outfalls were opened. I have noticed the water coming out of the outfalls at different times, and I could see and trace it down as far as Erith by the different colour. There is a very bad smell at times like a cesspool emptied two or three days. It is worse in warm weather about half ebb. I live upon the hill, and when I am half way down the hill, about from 70 to 80 feet above the level of the water, I get into the smell, and it seems as if I could not get out of it. You can get out of the factory smells, but out of the smell of the river you cannot get, and a very nauseous and unpleasant smell it is.

*Hind*, 1116.—I have found coming from the river a smell very much resembling a cesspool. Describes the offensive state of the bodies of persons drowned in the "Princess Alice."

*Cobb*, 1237.—Fishing nets are covered with all manner of filth. The water stinks enough to poison you.

*Savery* (*Customs Officer*), 1421.—On some occasions the state of the river has been very bad, particularly in warm weather. Last year, on two or three occasions it was unbearable on the water. It is worst in Halfway Reach.

*Farthing*, 1607.—Fourteen years ago the water was formerly taken by ships for drinking, now it would be poison. At high water in summer time it stinks awful, even up at Greenwich.

*Thorne*, 1744.—The same water is now very bad and black and stinking. It does not get up so far as Deptford. It comes about up to Bugsby's Hole and above.

*Parkinson* (*Pilot*), 1833.—The same; now it is rank poison.

*Brill*, 1966.—Water of a green greasy nature. Rots the nets. Plenty of lumps of sewage.

*Young*, 2034.—Rots nets. Boats' bottoms made much dirtier.

*Sibley*, 2090.—Very filthy. Very offensive smell, like a parcel of dead bodies floating about. Parties get their living by collecting grease.

*McKee*, 2203.—At high water, all dark fluid; floating masses of excrement and that sort of thing.

*Lee*, 2269.—Stuff from the human frame collects, stinking just like what it is. A lot worse than seven years ago. Slipway all slime, and during every low water always there, winter and summer. Dirties the boats. Increases.

*Hoskins*, 2347.—Filth, black; stench.

*Gatward* (*Constable*), 2646.—River very bad indeed after a hot day. Great quantity of refuse always left on the shore, smelling very bad, making you feel quite sick. Dead bodies from "Princess Alice" in a most beastly state; amongst the clothing there was a great quantity of slime and filth; when they had lain a few hours the smell nearly knocked you backwards when you went to them. Drowned bodies from other places looked fresher. Sometimes you cannot bear the smell as you go down the river; you are glad to run the boat ashore and get out of it. Seven men get their living by skimming the fat off the river. Lumps of filth floating about.

*Roberts* (*Police Inspector*), 2842.—The water has been very bad since the outfall was made. Bad smells emanating from it; most in close hot weather. Dead bodies from "Alice" in a very bad state after being a very short time in the water. Above Woolwich, water quite black. In the slack water, there is frequently lots of fat and slaughter-house refuse, and all manner of filth floating about.

*Carttar* (*Coroner*), 3014.—Bodies taken from the Thames are very much discoloured and disfigured. They turn various colours at various stages, and the decomposition is very rapid in summer, particularly in those that come from below Charlton; two or three days is sufficient. Often, deposits of mud and filth on the bodies; very offensive, and more so than with those bodies recovered from other waters with which I have to deal. A very marked difference. From Charlton down to Erith they come out worst. In a case on 16th July last, a body found after five days in Erith Wash was in a very bad state indeed, disfigured and swollen, and covered with filth and slime, and mud.

*Mastin* (*Policeman*), 3089.—Before outfalls were opened, there was not the foulness there is now. The water did not smell so bad. Dead bodies in a very decomposed state.

*Gilham* (*Police sergeant*), 3197.—River very bad indeed, thick and dirty. Smell very bad in hot weather. Bodies from "Princess Alice" were covered with slime and mud. The colour of their clothing was completely changed. They smelt very badly indeed. We had to boil the clothing before we could get it identified in many cases.

*Capt Lynch*, 3270.—Water dirty and thick before the Victoria entrance and Galleons entrance of Albert Docks. Closet filth floating.

*Showell* (*Inspector*), 3358.—Water in a filthy state; contains great amount of sewage. Worst smell in Woolwich Reach. Sewage matter floating. Coming up the river you would notice the change in the state of the water as you enter the Lower Hope, coming into Gravesend Reach.

*Rozier* (*Inspector*), 3466.—Water has been very bad in colour and stench since outfall opened.

*Capt. Hussey* (*Dock-master*), 3524.—Has seen the sewage eight miles above the outfall; it has got up now as far as Limehouse. Is of opinion it works its way higher up at the rate of about three-quarters of a mile a year.

*Shepherd* (*Tug captain*), 3898.—The river has been in a very bad state since the outfalls were opened. A lot of refuse swimming about with an odious smell; a stink of sewage. I should think it would not go further than the Lower Hope. Balls of sewage floating about.

*Edmunds* (*Barge builder*), 3969.—The lower reaches have become more foul year by year. A closet smell, but weaker, and more sickening.

*Marshall* (*Sexton of Erith*).—Bodies from "Princess Alice" were in a very dirty condition; clothing, one mass of filth; it looked like sewage; very horrible smell. Bodies from other parts of the Thames were not so.

*Naylor*, 4121.—The river has been in a much worse condition since the outfalls were opened; thick, muddy substance; smells intolerably. Dead bodies all in a filthy state.

*Showell* (*Inspector of Nuisances*), 4308.—Filth; sewage; great smell.

*Jesset* (*Medical Officer of Health*), 4430.—Thames, of late years, very bad. Bathing was formerly common; now it is impossible, by reason of the contaminated state of the river; increasing considerably. Last summer I saw large masses of sewage off Purfleet, as large as the table, floating about. Atrocious smell; have often noticed this.

*Armitage*, 4509.—Water very bad; very black indeed at certain times of the tide; bad stench.

*Brown*, 4592.—Water in a most filthy state; nothing but impure matter. Smell, enough to knock you down. Grease at the top, and underneath quite black.

*Martin*, 4687.—River in a filthy state as far down as Erith and Long Reach.

*Evans*, 4777.—Greasy stuff lies on the water.

*Rev. J. McAlister* (*Vicar of St. Nicholas, Plumstead*), 4795.—I have frequently seen sewage in the river, carried up by the tide.

*Lewis* (*Port Sanitary Inspector*), 5017.—There has been a most decided change in the character of the river between 1873 and the present time. In 1880 it was very black and very bad indeed during the summer, from Jenningtree Point up to Cherry Gardens Pier. Black patches; black stinking matter, which broke up at the slightest touch; patches many feet in length and breadth; stench fearful. Have traced sewage up to the lower part of Blackwall Reach. (*See* Note Book, Q. 5105.)

*Spadaccini* (*Port Sanitary Inspector*). (*See* Note Book, Q. 5276.)

*Capt. Marsden* (*Harbour Master*), 5356.—Smell in Halfway Reach most offensive and sickening. Stench and state of the river off Cubitt Town very bad. Black slimy appearance on the water. Very bad in Erith and Halfway reaches. River very much charged with sewage. Water very foul, and stinks from northern outfall to Erith.

*Showell*, 5423.—Have seen sewage at Woolwich and round the bight of East Greenwich.

*Capt. Fitzgerald, R.N.*, (*Thames harbour master*), 5487.—Change for the worse during the last five years; exceedingly bad in 1880. Quotes from note book, in which the following expressions occur:—"River water "most offensive; stream on flood and ebb apparently charged with sewage. Smell of sewage pervades the "river from Charlton to Erith quite as bad on the flood as on the ebb tide. Water strongly impregnated with "sewage. Very bad state off Charlton and Woolwich. Greatly discoloured with sewage in Bugsby and "Blackwall Reach. Water from Woolwich to Erith in a worse condition than I have ever known it; heavily "charged with sewage, and the stench almost unbearable. The Woolwich Reach almost black with sewage. "Immediately above Leather Bottle Point, the water was nearly black at the last quarter's flood, covering a "surface of nearly a mile. Sewage apparently washing its way higher up the river. River in a beastly state "again; one of the men sick. River choke full of sewage; landing places and foreshore full of it; stench "abominable. Patches of sewage all over the river; some six times as large as this room. River water "heavily charged with sewage; air bubbles visible right across the river." (Remarks more or less of the same nature are noted on 23 days in 1880, 16 days in 1881, and a few in 1882.)

*Capt. James* (*Harbour master*), 5743*a*.—Water in Halfway Reach was formerly drunk; it has now got very foul. (Quotes his journal: "Water very foul and offensive" many days in 1880 and 1881.)

*Dr. Collingridge* (*Medical Officer of Health to the Port of London Sanitary Authority*), 5855.—During the summer months, more particularly, the river water has been extremely bad. Whenever we have continued hot weather, more than two or three days successively, the water becomes darker in colour, and we get this very offensive smell, that, of course, being always worse in the neighbourhood of the outfalls; and I also notice there black patches of sewage. The condition is exaggerated and often brought on by agitation. The water may be pretty clear on the surface, but much worse underneath. I should describe the patches as very slightly diluted sewage. There is a very large amount of suspended matter, and the smell from it is horrible. Sometimes you come upon very large masses; you get matches, paper, and vegetable matter. The surface of the sewage stream has an oily appearance, which I attribute to the greasy matter in the sewage. I have traced the discolouration and floating fœcal matter up to Blackwall, and higher up.

(Refers to his reports, which are printed in the evidence, Q. 5931, &c. These Reports called attention in 1880, 1881, and 1882, to the unsanitary state of the river, which had attracted the attention, not only of the officers, but of the general public. Many complaints had been received and much anxiety was felt, lest, with the continuance of hot weather, severe consequences should ensue. Public opinion and public indignation had been aroused.

Suggestions were also thrown out as to whether, if the constant outpouring continued, the Thames would any longer be a proper or safe river for stationing the training ships.)

*Long*, 5946.—You could see lumps of stuff rise from the bed of the river, and then they would break open, and a fearful stench come from them, all black mud stuff.

*Young* (*Master of Conservancy Steamer*), 6133.—I have found very great changes indeed in the character of the water. It is now nothing but a mass of sewage. (Gives various extracts from log as to the dirty state of the water and its effects; could not wash down the vessel in consequence).

*Shand* (*Manager of London Steamboat Company*), 7055.—I have seen the sewage more particularly between Greenwich and Woolwich; at Woolwich it was very bad. The river was in a very filthy condition; the stench was something fearful, more particularly above the paddles of our boats moored from the pier. We have had continual complaints from passengers, from the captains, and the men; I looked upon it as a very serious matter on behalf of the company.

*Jones*, 7078.—I get my living by getting the fat off the river at Barking Creek. I collect it, and steam it and sell it.

*Capt. Webb*, 7113.—Change since outfalls opened. We get the stench further down. When we are running two boats together, the boat to windward stirs the stuff up from the bed of the river and causes a great stench to the boat to leeward. We have frequently complaints from passengers; if a boat happens to be passing us at the time, there is hardly a passenger on board but what is obliged to put his handkerchief up to his face to avoid the stench.

*Capt. Huntingford*, 7139.—I know Bull's Point abreast of the Arsenal to Woolwich Pier; the river is in a very bad condition. There is an eddy there.

*Martin* (*Pier Master, Woolwich*), 7172.—Water in the neighbourhood of the pier very different from what it was formerly; very black, much blacker; little balls of fat drive by.

*Custance*, 12,450. — Before the outfalls were opened the river at Erith was clear and wholesome and healthy; now it is very bad.

*Baldwin Latham*, 8005–9.—I have seen the river myself on one or two occasions when I have been down it this year, simply bubbling up from the effects of fermentation and black in colour. In the summer of 1878, when I was down the river, it was certainly most frightfully offensive, it was like sailing on the top of a cesspool, containing diluted cesspool matter. This was more or less so from Deptford to below Erith.

*C. J. More*, 9010.—I have noticed frequently in the summer time there is a most offensive smell in the reaches near the outfalls, from the water; there is no doubt about that. I have smelt it even at Woolwich in hot weather, when it has been stirred up by a steamboat, and there has been a horrible smell.

*R. W. P. Birch*, 9287–8.—The appearance of the surface of the river must be very striking to anybody who is constantly passing up and down; that is to say, the floating sewage. I have drifted up in a steamer amongst the sewage and seen the most undisguised sewage upon the surface up as high at Blackwall, and down the river certainly as low as Purfleet, pretty nearly every day. Standing on the sponsons of the tug, the spray from the water would come in your face, and you would be thus reminded of the sewage most distinctly. I have noticed that as far down as Erith on more than one occasion.

*Dr. Tidy*, 9925–9.—On 15 November 1879, he and Dr. Frankland saw a rapid stream of sewage, calculated at 20 to 30 million gallons [a day] flowing over the apron of the outfall at dead low water; owing to the steam given off it looked boiling hot, and the bubbling gases indicated the most active putrefaction; the smell was exceedingly foul. From that and other inspections, he is convinced that under certain conditions of water and of tide and so on, a very great nuisance undoubtedly exists.

*Dr. Frankland*, 10,686–701.—After the opening of the outfalls, the river markedly improved in purity; but since that time, from soon after the main drainage outfalls were opened, the purity of the river in London has been decreasing. As we went down the river, the water became more and more polluted. Corroborates Dr. Tidy's statement as to a very large discharge on one day of offensive sewage from the northern outfall at dead low water.

*Heaton* (*Lecturer on Chemistry at Charing Cross Hospital*) 11,335.—Disagreeable smells from the river in hot weather, miles away from the outfall.

*Professor Tuson* (*Lecturer on Chemistry*), 11,525.—The condition of the river is steadily getting worse and worse from year to year, from Woolwich Pier as far as Greenhithe. Has been getting worse for the last 10 years, judging from the appearance, the blackness of the river, its turbidity, and the stench arising from it. In Long Reach it is turbid, black, and sewagelike, with innumerable bubbles sluggishly rising and discharging gas, and in hot weather this is accompanied by a most fearful stench. There was bathing formerly at Erith, but there is none now. Corroborates Mr. Heaton's analyses.

*Professor Corfield, M.D.*, 11,759.—Found sewage flowing up stream from both outfalls; marked distinctly by the floating material, Stench very bad at both outfalls.

Sample taken off Woolwich was highly polluted (describes analyses of this and others).

Describes cases of illness due to immersion in the Thames at the time of the accident to the "Princess Alice."

104. The following popular evidence has reference more particularly to the deposit and accumulation of *foul mud* in the river:

*Beadle*, 264.—The mud deposit at Erith, is black disagreable mud, quite unlike what it used to be. There was a great deal of mud deposited in a vessel sunk; it had a great smell. The mud has grown up in Erith bay in the last 20 years, 10 to 12 feet. The river makes eddies there. The sewage collects there and deposits on the banks. The sun causes the matter to decompose and to give off a gas; that is what we suffer from most. The causeway has been lengthened 100 feet. They are now obliged to have a floating one. It has been growing up for the last 15 or 20 years, more particularly the last 10 years. A slimy black mud, much dirtier, and more offensive than ordinary Thames mud, and when the sun is out, much more offensive than any mud I know. It never was so bad as it is now. Each year now would double this evil. The worst point is from Jenningtree Point to Erith. It is silting up in Church Hole very fast indeed.

*Busby* (*Pilot*), 453.—I have had a vessel lying at Erith, and the place has been very nearly ankle deep on the shore with the slush which has come out of the sewer. Erith, you may say, is the essence of the jelly bag; they get it worst there.

*Sandford* (*Pilot*), 553.—The mud is accumulating fast under Crossness. There has been a greater deposit of mud on the south shore in the last five or six years. It is marvellous how it has grown up there.

*Mr. Harry Leach's Medical Report on the "Cornwall,"* 863.—It is important to notice that the adjacent foreshore (near Purfleet) is frequently covered with decomposing sewage, brought by a strong ebb tide from the Metropolitan drainage outfalls at Barking and Crossness.

*Egerton* (*Erith Surveyor*), 901.—The river has altered very much during the last 21 years. The water has receded. There is very much more mud about Church Hole than there used to be. When the sun is out very hot, and the wind is off the water, it smells very bad.

*Hind*, 1103.—The causeway has been lengthened and raised because the mud grew up so much around it, that it was entirely covered. The mud has been accumulating ever since the outfalls were opened. It is black stinking mud; at the end of the causeway there must be at least 10 or 11 feet perpendicular of solid mud or muck. The smell is altogether different from what it was when the sewer was opened.

*Cobb*, 1244.—There is something at the bottom of the river that smells worse than any closet. The same at Church Hole. It gets worse and worse every day. An anchor was lost in the mud. From Erith and a little below Erith, and up to the outfall, and a little below the outfall, we get that black dreadful sewage along the banks. I have recently on some occasions gone and lifted some with a scull, and it seemed to me to be pure black sewage. I found an enormous accumulation along the outfall right up that reach to the point at the top of Erith reach and right away down Erith Reach. On the south shore above Erith, there are very large deposits of mud, where the steam boats used to go in at certain times of the tide without difficulty, but now they stir up the sewage and they get in with great difficulty. There has been an increase during the last few years. The banks appear to be solid black sewage. At low water on a hot day, it smells dreadfully. The sewage lies by the Causeway in heaps and piles, and it is unquestionably accumulating; it is black and smelling. No deposit much below Erith, that is the great receptacle; there is no doubt to any one observing, as I have done daily, that the increase there is enormous, many feet deep all of the same character, not such as you would get from the banks of the Thames.

*Hathaway*, 1556.—Accumulation of mud at Erith Causeway; nasty black stinking stuff, you cannot call it mud, it is not mud.

*Farthing*, 1633–6.—If you let go an anchor, it is like hauling up so much grease, you would hardly make out whether the anchor was iron or a lump of muck. A mixture of mud and slime like grease, smelling beastly. All the way up and down along the south shore from the sewers, right down below Erith.

*Clarke*, 1692.—All a black slimy mud up to your middle.

*Thorne*, 1778.—It is not mud, it is more like slime; black, very black indeed.

*Parkinson*, 1829.—Before the outfalls were made, the shores were clean mud, now it is all sorts of colours; where it was sand, it is all muck. Where we had 15 and 16 feet of water in Halfway Reach, we have about 9 feet now. Muck on the anchor and chains; it is not mud, and it smells fit to choke you; you have a boat to sweep it off to prevent it coming on board; I think it gets worse and worse every year. Where barges used to get sand, it is now all muck.

*Brill*, 1940.—Shore all slushy muck, imitating a cesspool; smells very strong. Growing very fast lately all along Erith, if it washes away, it very soon appears again. It still increases.

*Young*, 2020.—Bottom nothing else but all filth. Anchor line three inches thick with muck and paper and all manner of filth; smells dreadful. Anchor would not hold, it is all of a "slather."

*Sibley*, 2098.—A very great deal of slush like night soil; increases wonderfully. Creek fills up with it. Nothing but sewage collects in Church Hole.

*Hoskins*, 2367.—Filth increases.

*Faulkner*, 2443.—Black mud smells like night soil, created on the shore at Erith; increases. Black like closet stuff. Stench in summer. Stuff from the closet comes down there whole, not washed to pieces. Increased 8 to 10 feet in the last 18 to 20 years.

*Harling*, 2537.—Filth all along the shore, greasified; like your own manure in great lumps all along the sides of the dock; dung; closet stuff, black stuff, not mud. Accumulates in the docks.

*Clarke*, 2609.—Black nasty filth, like stuff from the human body. It creates more, and gets worse.

*Gatward* (*Constable*), 2650.—Greasy slimy stuff. Mud and slime stuff, and stuff on causeway with very great smell. Mud along the foreshore like filth.

*Roberts* (*Police Constable*), 2859.—Mud terribly black and dirty, and smells very badly when washed up by steamers. Accumulated until recently, but now drawing off.

*Mastin* (*Policeman*), 3098.—The mud has a very offensive smell.

*Gilham* (*Police Sergeant*), 3222.—The causeway at Woolwich has to be washed down as the tide recedes. It is very slimy and slippery, and covered with filth, generally black mud. Bad, smelling in hot weather.

*Capt. Lynch* (*Dockmaster, Albert Docks*, 3275).—The mud in the Albert Docks has accumulated very fast in the last two years. Blacker in appearance. Smells very much.

*Showell*, 3363.—Mud in a very bad state. Dreadful stink.

*Rozier*, 3476.—Mud quite black. Offensive smell in summer.

*Capt. Hussey* (*Dockmaster*), 3503.—There has been an enormous difference in the accumulation of the mud at the entrance of the East and West India Docks in the last three or four years, and especially this year. At first there was a decrease after the outfalls were opened, since then it has been gradually increasing, working its way up. In 1879, 60,000 tons cleared the whole, this year it is estimated at 160,000 tons. A large proportion of it is sewage. The stench from it is something awful in the summer time.

*Fuller* (*Dredging Contractor*), 3611.—Used to dredge clear building sand at Jenningtree Point and elsewhere; but since the outfalls have been opened they have been driven lower down, and have now to go to Coalhouse Point, below Gravesend. Ceased to dredge at Jenningtree Point after the sewer was opened. Customers complained of the filth in the sand. The Gravesend sand is spoilt now, being covered with filth to a depth of 18 inches. Our frontage of 1,000 feet at Woolwich is in a dreadful state, covered with about 18 inches of this filthy stuff. In summer it smells awful. I call it sewage. Barges sunk get a bad sediment of mud and sewage.

*Williams* (*Dredger Captain*), 3718.—Have found a great deal of soil in Long Reach. Sometimes the gravel is dirty; quite sewage.

*Whitehorn* (*Dredger Captain*), 3791.—Left Erith Reach on account of the badness of the stuff. With a bucket of gravel we should have a quantity of sewage matter.

*Capt. Shepherd*, 3917.—The mud on the banks is black and greasy, with a very bad smell like sewage.

*Edmunds*, 3982.—Thick mud and very stinking.

*Saunders*, 4036.—Great accumulation of sewage stuff in the berths when the ships come, and we have great difficulty in keeping them clean. Nasty sort of smell. Barge sunk was in a fearful state when raised, with a kind of sewage mud.

*Showell* (*Inspector of Nuisances*), 4318.—Mud more like filth and such like along the shores. Sewage settles down in Halfway Reach and about Erith. Deposits 8 or 10 feet deep.

*Evans*, 4409.—Grapplings are choked with so much filth, slime, and stinking mud. Can hardly bear the stench in the summer.

*Jesset* (*Medical Officer*), 4464.—You see the gases bubbling up through the mud at low tide constantly.

*Armitage*, 4511.—The settlements along the shore are quite black and slimy. At Long Reach very bad indeed. Solid banks of mud seven or eight feet high.

*Brown*, 4592.—My cable and anchor when I heave it up are blacker than my clothes. Nothing but stinking filthy matter.

*Martin*, 4687.—River fills up very much with mud and slush and muck. Stinks filthy.

*Tall*, 4736.—Dirty filthy black mud. Stinks very much. Increasing fast.

*Evans* (*Dredger*), 4772.—At Jenningtree Point formerly the sand was always very good and clear, but of late years it has been very filthy and dark. In warm weather we could scarcely stand to our tools to work it for the stench and the refuse under the sand.

*Rev. J. McAlister* (*Vicar of St. Nicholas, Plumstead*), 4802.—I have frequently and carefully examined the deposits on the sides of the banks. It was evidently human excrement in a state of decomposition, breeding living creatures, and having a very offensive smell, particularly in summer. All over the parish, a distance of three or four miles from the river, it is very offensive indeed. Very strong.

*Lewis* (*Port Sanitary Inspector*), 5119.—There is a mud bank near upper outfall which stinks very much. I cannot describe it. It is fearful. The boatman happened to put his oar in there. I had a man and a boy in the boat, and it knocked the boy up. He was ill for a day or two. It was really shocking.

*Capt. Fitzgerald* (*Harbour Master*), 5542.—Foreshore and some of the landing places are clothed with sewage mud. Mud increasing in the river in some places, black and stinking.

*Dr. Collingridge*, 5918.—The mud deposited on the banks, particularly nearer to the outfalls, is dark, slimy, black stuff, and has a peculiar gelatinous appearance.

*Hughes* (*Solicitor to Woolwich Local Board*), 6687.—There is an increase of the filth on the banks of the river since the opening of the outfall. It used to be a natural mud, now it is an artificial mud. You cannot land from a boat now in many places where you used to be able to land, but you now come against a mud bank, and if you got out, you would be suffocated. The colour of this deposit has entirely changed since the opening of the outfall. It is as black as ink.

*Martin* (*Pier Master, Woolwich*), 7184.—We have sometimes two or three steamers at a time, and then they stir the mud up; and it is a sort of blue black colour; and the stench is something horrible then. It is simply awful.

*Wood*, 12,384.—Near Dagenham in 1861 the ground was perfectly clear, a hard shingle; in 1882 there was nine feet of mud on the same spot, black mud, all sewage. Barges lately raised at Northfleet Hope had a great quantity of mud in them; it smells and is very black. The mud is all sorts, sponges, and rags, and guts, and all sorts of things.

*Capt. Burstal, R.N.* (*Secretary to the Thames Conservancy*), 6391, &c.—Mud banks have been deposited since 1861. The bank on the north side of Barking Reach is composed of very black mud, very deep, and very slimy, with not much sand or gravel in it; not at all like ordinary river mud. In warm weather it smells very badly. This applies also to the mud in Erith Reach and other banks in the neighbourhood. There is slack water in some places. There had been no accumulation on the south shore at Erith before 1861; now a very large accumulation has taken place all the way along the shore, to the depth of 7 to 10 feet vertically. It extends three-quarters of a mile. There is still an accumulation going on. The causeway has been lengthened 150 feet. He produces sections of the river at Erith, showing the accumulations.

*Mansergh*, 8730. — By plotting areas in Half-way Reach we have found a constriction in the river; the deposition of the mud has made the river too small for its work, showing that there is some exceptional cause at work to keep the river small. Either the stuff itself cannot be removed by the currents, or, if it is removed, it is immediately replaced. This mud is caused by a deposition of the ordinary suspended matter of the river *plus* the ordinary suspended matter of the sewers; and anything that points to such an accumulation of dirty mud is to the point in this case.

There is some abnormal cause which allows the river to remain constricted at that point. (*See also* 9065 to 75.)

*More*, 8967.—Finds accumulations of mud in many parts of the bed of the Thames. It is found, in parts, almost entirely across the bed; at other parts it is simply in bights. (*Puts in plans which show this.*)

The mud is of all depths, from 6 or 7 inches to 8 or 10 feet deep. It is evident that it has been brought there, because the natural bed of the river was gravel originally.

There is not much in Bugsby's Reach, except on the foreshore. Woolwich Reach is a very muddy reach indeed; there is a very large deposit of mud there, extending almost across the reach, the depth varying year by year. Galleons Reach, upon the Essex side, is very muddy indeed, all along the bight. Near the Beckton Gasworks there is a great depth of mud, which extends as far as Barking Creek all round the lower end of the bight; this is 6 or 8 feet deep. Barking Reach is very muddy from Margaretness on the north side to Crossness on the south side, and from False Point as far as opposite Dagenham on the north side. It extends very nearly across at one point. Half-way Reach is extremely muddy, especially all along the south side where the southern outfalls are—this is 9 or 10 feet depth far out into the river, and that mud is gradually extending down to the lower end of the reach, and further out into the centre of the river. There is also mud off the north side, opposite Jenningtree Point. In Erith Reach from Jenningtree Point down to Erith, all down the Kentish side of the river, is muddy; there is a great quantity of mud and of great depth towards the lower end of the reach. Off the town of Erith there is a very great deposit, 6 or 7 feet deep, going about one-third of the way across there. This has rather increased lately. The latest soundings show rather more mud than before at Crayfordness. You find mud in the centre of the river.

Between high and low water marks there is a great deal of mud all the way down past Gravesend. Knows places which he can remember quite clear, or, at all events, so that you could land from a boat without difficulty, where you have now 3 or 4 feet of mud.

The mud extends in area year by year. It has increased mostly in the neighbourhood of the outfalls in Barking and Halfway Reaches.

It is a very black, slimy sort of mud. It is blacker and of a more offensive character near the outfalls than elsewhere in the reaches; its offensive character is very much complained of by the men who are engaged by the Conservators to raise anchors and so on.

Puts in sections of the river near Erith. They show a very large accumulation of mud in 1882 since 1861 on the south side.

The flow of the stream is very variable indeed in the crooked parts of the river above Long Reach; there are eddies round the points.

Puts in area of cross sections of river at Erith, showing increase and decrease.

*Dr. Frankland*, 10,835–40.—Is of opinion that the river is rapidly becoming worse from the accumulation of mud banks which are increasing from year to year; these putrify in warm weather, and create a permanent nuisance. Thinks even if the amount of sewage thrown in does not increase, it will become worse, as the mud banks will go on increasing.

*Heaton*, 11,336.—Disagreeable smells from the mud.

*Tuson*, 11,534.—A quantity of stuff collects on the bottom of the boats; a blackish kind of mud, and when it is scraped off the stench from it is very bad, like the smell of fæcal matter decomposing.

*Dr. Browning* (*Medical Officer of Health for Rotherhithe*), 12,078–81.—Has taken specimens of mud near the outfalls, and at Wapping and Rotherhithe. It was very black and very fœtid, and showed evidence of sewage.

105. We have been informed by the complainants that this great mass of evidence is by no means the whole they are prepared to bring forward. They have tendered to us 282 more witnesses to the same facts; their names and heads of evidence being given in Appendix C.C. They comprise—

24 yacht owners.
55 captains of barges, &c.
85 free watermen and pilots.
61 fishermen.
57 general witnesses.

The reason we did not require the attendance of these witnesses was that it was admitted they were trustworthy persons, meaning to tell the truth, and that they would repeat the same evidence and opinions as had been previously given by others. Consequently their attendance would only have led to an unnecessary expenditure of time and money.

106. The popular evidence, from direct observation, offered by the respondents in answer to the above, has been as follows:

*Chatterton*, 12,970.—During a long time he was engaged in Long Reach, there was no perceptible smell of any kind, but there was an indication of the sewage. By watching the river very closely on a very calm day, you could notice cork and bits of vegetable, and traces of grease, &c., which would float upon the surface, but there was no possible means of detecting any large bulk of sewage by the nose or the eye.

In June and July 1877 never heard of any complaint; never noticed any offensiveness, and does not think it possible for anybody to have told whether there was sewage being discharged at the outfalls or not. His men used to bathe in the river in hot weather. He does not agree that the river would become noxious at about 65°. Many days that it was above that he never heard of a complaint.

Was 59 days in 1882 on the river making observations and taking samples. Followed the sewage down from the outfall. Near the outfalls it was very offensive. At less than half a mile down the traces were visible, but there was no smell in the air, although the water smelt when shaken violently. At 1¼ mile the water smelt faintly when shaken. At two miles below Crossness there was no smell. At Purfleet all traces were lost.

There was no smell in the Thames last year, unless you went into the immediate neighbourhood of the outfalls; the bad smells were from the factories on the shore, the Beckton Gas outfall, the Bow Creek sewage from West Ham, and so on. Much sewage is discharged into the river independently of the main outfalls.

There are great local nuisances from the Erith outfalls, and from factories on both sides of the river.

*Coleman*, 13,485.—The bodies from the Princess Alice had no particular appearance of sewage. Has been surprised how little smell there was stirred up by the paddle-wheels at Woolwich Ferry at low water. The smell from the factories is frightful at times.

*Law*, 13,972–3.—No person passing up and down the river, if they were not told that the sewage was discharged into it, would ever find it out, unless they were to row within, perhaps, a distance of 100 yards of the outfall. Compared with the offensive stenches from other sources, the nuisance of the sewage is inappreciable.

*Easton*, 15,207, &c.—The sites of the outfalls were well chosen; no more suitable positions could possibly have been found. Refers to his reports on the bad drainage of Erith, and the local nuisance arising therefrom. He recommended a proper system of sewerage, with deodorizing works. Off Crayfordness, when the sewage was discharging, there was no smell of sewage, or anything else in it. The chemical works are very offensive.

*Tatham*, 15,431, &c.—Has not heard any complaints for the last two or three years of the bad state of the river; two or three years ago they used to complain sometimes. In the hot weather he has noticed a little bad smell towards Blackwall. The water in the river is much clearer now than it was two or three years ago.

*Dr. Dickson*, 15,537.—Occasionally in hot weather there has been an unpleasant smell where the mud has been stirred up by the steamers, but not lately.

*Dibdin*, 15,701.—The Erith sewage is far fouler than anything obtained from the Board's sewers, and is a great deal more than sufficient to account for the complaints from the Erith people. Although the temperature of the Thames has been sometimes nearly up to 70 degrees, yet the odour was nothing more than you would find either down at Southend or up at Teddington. The factories are very offensive.

*Dr. Dupré*, 16,106.—He was 17 days on the river in the summer during July, August, and September; he could not on those occasions perceive any offensive or disagreeable smell from the water, except in the immediate neighbourhood of the outfalls. Has frequently examined the water at the spot where the "Princess Alice" went down, and never found it offensive. The actual stream of the sewage in hot weather is very offensive and very nauseating, but it is not a very powerful or penetrating smell, so that it is very soon lost; even if you go down in the actual sewage stream in ordinary weather, you lose the smell in about 1,000 yards; at 2,000 yards you see the stream by the floating matter—small pieces of cork and vegetable matter, and even small pieces of excrement, but it does not smell. Within a few hundred yards the sewage very rapidly mixes with the general body of the river. There are very bad smells from the factories and other sources.

*Sir F. Abel*, 16,261.—He has inspected the river several times in 1878, 1880, 1881, and 1882, and except when actually in the sewage flow, has only on one occasion at a distance from the sewage been able to recognise the distinct unmistakeable odour of sewage, and in that particular case there was a pretty steady and strong wind blowing towards him from the outfalls; this was between 1,000 and 1,200 yards from the outfalls. After 50 to 100 yards it becomes comparatively feeble, except when the water is stirred up by steamers. Has lived for 28 years at Woolwich Arsenal, within 180 to 250 yards of the river, and has not experienced any annoyance from it.

*Dr. Voelcker*, 16,366.—Bad local nuisances from Erith, sufficient to account for the complaints. No bad smells from the river except direct in the sewage stream, and this disappears at a distance of 600 to 700 yards. Bad smells from the factories. That there is a local nuisance cannot be denied; you cannot discharge a large body of sewage without it, but it is remarkable how quickly it is destroyed. He would limit the nuisance to 1,000 yards, or less.

*Dr. Odling*, 16,491.—The river, as a body of water, does not smell offensive or look offensive. There is no evidence to the senses that it is polluted; in warm weather the smell given off by the discharge of the sewage stream is sometimes offensive and nauseating; but it does not spread very far—not anything like a mile from the bank. The sewage could scarcely ever reach Woolwich in an offensive state, if it is discharged upon the turn of the tide.

*Dr. Sorby*, 16,592.—Lived in a yacht for some months in the warm part of the year near Erith and Greenhithe; and not one of his crew had the slightest fault to find with the river.

*Mason*, 16,833.—Has not noticed any smell from the river at Barking or East Ham; in the water at Barking at high water he has never noticed any indication of the presence of sewage. Saw a number of the bodies brought ashore from the "Princess Alice," did not observe anything unusual about them; saw no indication of sewage poisoning.

107. As to the allegations in respect to the *foul mud*, the respondents' witnesses testify as follows:

*Chatterton*, 12,971.—Became practically acquainted with the mud, some six or seven miles below the outfall, and never found it differed from ordinary Thames mud, or more disgusting in smell, or in any other way than any other mud. Does not think it possible, as far as the eye or the nose is concerned, to detect any change in the mud or the foreshore since 1877. The set of the tide has altered through the dredging.

As far as an ordinary person can detect there is no difference between the mud in Erith Bight and the mud at the mouth of all the creeks down the river.

Erith being in a bight the sewage never passes into it; it is deflected to the Essex side. Has never seen a float go into Erith bight at that time of the tide. The sewage cannot get there on an ebb tide.

*Law*, 13,880.—The Thames must be a muddy river. The mud washed from the banks contains nearly as much polluting matter as the mud from the sewage. Much detritus is brought down from above.

The mud of the river was in a bad state, and gave off poisonous gases in 1839, before sewage was turned into it. At the time of the Mud Inquiry the mud was found perfectly inoffensive, and no difference could be detected in any part of the river.

*Easton*, 15,224.—No more accumulation of mud at Erith now than there always has been. There is no gradual increase. Sand being dredged at Crayfordness was bright sand, used for building purposes. There was no offensive smell from the mud at Erith. Cannot see how the sewage from the metropolitan outfalls could be deposited on Erith bight. The deposit of animal matter at Erith practically arises from the Erith drainage.

*Dibdin*, 15,754.—There is no practical difference whatever in the composition of the mud from the various banks in the neighbourhood of the outfalls, between 1879 and 1883. A pure river in Queensland contains organic matter to nearly the same extent as the Thames.

*Dr. Dupré*, 15,966.—The Thames generally is muddy. The composition of the suspended matter in different parts of the river is very much alike, but sometimes it is worse at Teddington than at Crossness. All along the river from Teddington downwards the mud is very much the same; if there is a difference, that of the upper part of the river is slightly fouler than that of lower portion; almost the worst bank in the whole river is at Westminster. The bank at Erith does not differ in any way from the banks in other parts of the river.

*Sir F. Abel*, 16,231.—All muds which contain vegetable matter become putrescent, and emit an unpleasant smell. The black appearance of the mud, which gave to the uneducated mind a notion of filth and impurity, is really due to a purifying action. He visited the causeway at Erith in June and July; although he carefully searched for smell in the mud itself, he was unable to detect any.

*Sorby*, 16,642, &c.—In the mud banks complained of at Erith he finds exactly the same sand as is found in the old saltings, and considerably differing from the sand in the sewage.

The mud deposited at Erith differs from pure normal river mud by containing only a very small per-centage of material derived from the sewers, and less than one per cent. of that of objectionable character.

108. Members of the Commission on four occasions went on the river from above the outfalls through the sewage while discharging, and did not experience a sensible nuisance, except near the outfalls. On those days the weather was cool, there was a breeze blowing, with much fresh water, and on one occasion with a high spring tide. These were not days of such a character as those in regard to which the chief complaints were made; and the seasons were such that we were unable to find days convenient for our observation, when the combination of circumstances occurred, which have been described as causing or developing the nuisance.

*Scientific Evidence.*

109. In addition to the popular testimony as to the alleged nuisances from the sewage discharge, we have received a large amount of evidence on the same point, but of a different character, namely, evidence in which inferences are drawn by scientific reasoning.

A number of scientific witnesses, of high standing, have appeared before us, and an enormous mass of documents of various kinds has been put in, illustrative of the statements they have made.

We do not think it necessary to give any complete analysis of this evidence: there is much conflict of opinion as to the interpretation of the facts observed, and many of the points touched upon are confessedly obscure. And, on the whole, we are not inclined to attach so much weight to considerations of this speculative character, as to well substantiated statements derived from actual observation.

Moreover, while accepting in the main the facts presented to us, we have often found it difficult to determine their relevancy to the matters under inquiry.

All we propose to do therefore is to give a very brief indication of the general nature of the evidence in question.

110. On both sides, we have had engineers, chemists, and microscopists, all gentlemen of high professional standing.

On the part of the complainants:

*Mr. Baldwin Latham, Civil Engineer*, gives data and calculations as to the influence of temperature on the offensiveness of the discharge.

He further gives statements as to the quantity of solids in the sewage, and the probability of their deposit.

*Mr. Mansergh, Civil Engineer*, explains why, on engineering grounds, he considers the nuisances probable, particularly as regards the deposit of foul mud.

*Dr. Tidy* gives elaborate analyses of the water at different points of the river, which are referred to as showing the deterioration it suffered by the admixture of the sewage.

He also gives theoretical estimates of the quantities of offensive solids discharged into the rivers, and analyses of muds, to show their sewage origin.

*Dr. Frankland* has also made extensive independent analyses of other portions of the river, and gives copious statements of inferences from them, as also from the analyses of Dr. Tidy. He further gives elaborate calculations of the solid matters discharged.

*Mr. Heaton and Professor Tuson* give analyses having a similar tendency.

*Professor Way* gives statements and calculations showing the nuisances to be probable.

*Dr. Lionel Beale* describes a microscopical analysis of mud, showing it contains matter of sewage origin.

The respondents' scientific witnesses on this point are as follows:

*Mr. Law* asserts the large dilution of the sewage, which renders it innocuous.

He explains that the river is rendered naturally muddy by the washing away of the banks, &c., and states that the mud complained of is only the ordinary mud of the river.

*Mr. Dibdin, Dr. Dupré, Sir F. Abel, Dr. Odling, and Dr. Voelcker*, all testify to the efficiency of the purification effected by the oxidizing action; and assert that the purifying power is in excess of the present polluting influences.

*Dr. Sorby* adds that a large part of the more objectionable constituents of the sewage is removed in summer by the unobjectionable action of minute animals.

*Dr. Odling* asserts there is no definite body of polluted water which can be distinguished from the general mass of river water.

Several witnesses contest the statements made on the other side as to the solid contents of sewage.

111. On the whole the chemical analyses show that there is a progressively increasing impurity of the river from Teddington downwards to the outfalls; and then a decreasing impurity down to Gravesend, below which place the sewage is not perceptible. The oxygen dissolved in the water exhibits a corresponding decrease where the impurity increases, and *vice versâ*.

This shows not only the impurity of the water at and near the outfalls, but also that the oxygen does active work in oxidizing and thus purifying the sewage impurities in the river.

Besides the purification of the river by oxidation, there is evidence of its purification by means of animal and vegetable life. Animals of a low type, notably *entomostraca*, (such as water fleas) feed upon the solid elements of sewage. These animals themselves excrete solid matters, but of course in a diminished amount; the balance is decidedly in favour of purification.

Minute algæ and other plants of low organization vegetate in the polluted reaches, and, by giving off oxygen, they tend to promote the purification of the water.

The nett result of these complex processes:—pollution by sewage, oxidation of the sewage, consumption by minute animals, and re-oxygenation of the river by the action of vegetable life, and by renewed absorption of oxygen from the air, is, that in cold weather and in cool wet summers the pollution of the river water exists indeed, but does not increase; the above processes being adequate to prevent that. But during hot dry weather the pollution increases, exceeding the purifying power of the agents for its removal; and the river then becomes a nuisance, more or less great, and within greater or less limits.

*Remarks.*

112. Reviewing now the whole of this important part of the case, we find the real question to be, Is there a nuisance? and if so, to what extent? This seems to us substantially a question of fact; the scientific evidence, on either side, only tending to show that such a nuisance may or may not be expected.

We find it impossible not to be satisfied, by the overwhelming amount of concurrent evidence, much of it from indisputable sources, as to the real existence, under certain conditions, of the nuisances complained of.

It is altogether incredible that such a wide-spread feeling of dissatisfaction should prevail without reasonable ground, or can be the result of mistake. There is no reason to believe in any general hostility to the Metropolitan Board, and it seems impossible to account for the agitation, except for the justifiable motive of obtaining the removal of grievances which are felt to be serious and substantial.

113. The answer of the respondents to this evidence, so far as it can be inferred from the cross-examination, from their own evidence, and from the addresses of their counsel, appears to embody the following points.

*That the offensiveness of the sewage discharge is removed by natural purification in the river.*

We believe this has been fully substantiated, to the extent, at least, that no nuisance is proved beyond certain varying limits, above and below the outfalls. But it is between these limits where the offensiveness under certain circumstances exists, and it is to this space and to these circumstances that the complaints apply.

*That rebutting evidence has been given of the non-existence of the nuisances.*

It is true that several witnesses of high character have stated they have not experienced them, but as the nuisances only occur at certain times this is not inconsistent with the complainants' testimony, and cannot outweigh the immense accumulation of evidence to a contrary effect. Besides, it is admitted by many of the Board's witnesses that nuisance does occur within a certain distance of the outfalls.

*That the complaints have been much exaggerated.*

No doubt some of the statements are very strong, but even supposing that they may have been in some cases highly coloured, the fact only shows that a strong feeling

must have been aroused by the real existence of the evil. We may, however, make a very ample allowance, and still find sufficient remaining to substantiate the case; and we believe that we are making such an allowance when we limit the extent of the evil as we have done. The existence of the offensive smell and other matters complained of is a nuisance which ought not to occur if it is preventible.

*That the offensive smells complained of are due to chemical works and manufactories of various kinds in the neighbourhood of the outfalls.*

The existence of large numbers of these works, some of them giving off offensive effluvia, has been fully proved; but although the witnesses have been much pressed on the point in cross-examination, we believe it has been established that the sewage nuisance is sufficiently distinguishable from the factory smells. Our own experience, in the personal inspections we have made, confirms this view.

*That the nuisances are further due to local sewage from Erith, North Woolwich, Beckton, West Ham, and Barking, from the floating population, and other sources, not within the control of the Metropolitan Board, and also from manure and other offensive matters carried in barges on the river.*

The existence of some such nuisances has been shown: but it seems strange reasoning to refer the complaints to these comparatively insignificant sources, when a cause of immensely greater magnitude, of the same nature, is close at hand. And it is impossible to believe that the vast numbers of witnesses can universally have been deceived into attributing to the London sewage evils arising from the local causes mentioned in this and the preceding heads.

*That the complaints result from an agitation got up for the purpose.*

This appears solely to be founded on the fact that a meeting was held at a public-house, at which a certain number of the lower class of witnesses attended, and where the depositions were taken. But the objection has no value whatever, as it has never been alleged that there are any parties interested in getting up such an agitation, except for the legitimate purpose openly avowed. We have entire confidence in the good faith of the complainants and their witnesses.

*That, in regard to the complaints of the foul mud, the Thames is naturally muddy, the mud in it is generally offensive, and the deposits complained of do not differ in their composition from those in other parts of the river.*

To adopt this view would be simply to ignore the evidence on this point, or else to assume that the witnesses must be ignorant and incapable of judging of the matter they testify to, which we cannot believe.

*It is further said, that the positions of the outfalls are justifiable because of the many sources of nuisance in the immediate neighbourhood of them.*

We cannot consider this argument sound. The local nuisances have been much complained of, and they can be dealt with by law if they become intolerable. In any case, it seems to us a perversion of reasoning that their tolerance should be pleaded as a justification for adding to them.

We do not consider that by any of these objections, the immense amount of positive testimony to matters of actual fact has been invalidated.

114. And when we reflect on the magnitude of the causes in action, it is hardly surprising that some such effects as those complained of should occur.

In the first place, the daily quantity of sewage discharge is, as we have said, enormous. The flow of sewage proper is estimated at an average of 16,000 cubic feet per minute, which is 23,000,000 cubic feet per diem. Now the river at low water in the neighbourhood of the outfalls is about 2,000 feet broad, and has a sectional area of about 30,000 square feet, so that there is discharged into it every day as much undiluted sewage as would fill a length of 750 feet of this part of the river at low water.

Then if we estimate the quantity of foul matter which this discharge must of necessity contain, we arrive at quantities equally astounding. The quantity of fæces alone, in their natural state, passing from 3,800,000 people, has been stated at something like 400 tons a day; but if we consider also the urine, and the foul matter from other sources, and of other kinds, the total quantity must be very much larger.

The idea that these large quantities are unimportant in comparison with the

magnitude of the river into which they are discharged is, as we have already shown (paragraphs 87, 88), incorrect.

It would be difficult to suppose that such enormous amounts of polluting material could be destroyed by purifying action in so short a time as would be necessary to free the river from nuisance in the neighbourhood of their discharge. It is surprising that the nuisance is so far mitigated as we find it to be.

115. We do not find any reason to believe that the offensive exhalations are perceptible in such a degree as to cause nuisance to any great distance inland from the banks of the river. There has been some evidence to this effect, but it is not strong enough to satisfy us, and it is more probable that the offensive smells that penetrate inland are due to the factories. We consider that whatever nuisance there is affects only persons who are either on the river or on its immediate margin.

There is evidence to show that the suspended solid matters in the sewage are to a greater extent the origin of the offensive smells than the dissolved solid constituents of sewage.

---

## (C.)

### Injury to Fish.

116. Another of the complaints made of the effects of the sewage discharge is that of injury to fish, in the part of the river near the outfalls.

The testimony of all the witnesses on behalf of the complainants, in regard to this, is the same, namely, to the effect that, whereas formerly fish were caught in the neighbourhood of Woolwich, Erith, and so on, since the main outfalls have been opened the fish have been driven down to a much lower point, *i.e.*, to Gravesend or below. It is now, at times, impossible even to bring them alive through the water of the river above Gravesend.

It will only, therefore, be necessary to refer to the witnesses' statements, without quoting their words. They are—

*Beadle*, 231; *Busby*, 472; *Sandford*, 596; *Walter*, 733; *Egerton*, 953; *Hind*, 1122; *Cobb*, 1216; *Savery*, 1447; *Hathaway*, 1524; *Farthing*, 1622; *Thorne*, 1748; *Brill*, 1932; *Young*, 2006; *Hoskins*, 2331; *Faulkner*, 2439; *Harling*, 2527; *Gatward*, 2682; *Showell*, 3366; *Showell*, 4348; *Armitage*, 4502; *Plumb*, 4652; *Martin*, 4698; *Brown*, 4759; *Passfield*, 4965; *Capt. Jan Visser*, 5213 *Capt. Marsden*, 5356; *Capt. James*, 5744; *Young*, 6148.

Many more witnesses to the same effect were offered: see Appendix CC.

117. These facts were admitted by the respondents, but the effect was attributed by them, not to the noxious qualities of the sewage, but to the absence of oxygen, which had been abstracted from the water in effecting the purification of the sewage.

Without deciding whether this is the true or the only explanation, the facts remain, that the fish have disappeared from this part of the river, and that their disappearance is due, either directly or indirectly, to the sewage discharge.

No evidence has been given before us to prove the actual loss sustained by any parties from this, but it must be to some extent an evil, and it should not be lost sight of, if the possibility of remedy is inquired into. Indeed, broadly speaking, if fish cannot live in a river, such river cannot be in a natural or satisfactory condition.

---

## (D.)

### Pollution of Wells near the River.

118. Another ground of complaint brought before us has reference to the possible pollution, by the sewage, of wells on the shore in the neighbourhood of the outfalls. It is said that under certain circumstances, the water of the Thames may flow into the permeable strata from which such wells are fed; and it is argued that when the Thames water is fouled by sewage the pollution may penetrate into the wells, and so produce serious consequences.

119. The following evidence bears on this point.

*Whitaker* (*F. G. S.*), 6986, &c.—In the lower Thames, near the outfalls, the strata are chiefly permeable.

Therefore, there is plenty of opportunity for the infiltration of water from the river into the beds from which water may be drawn for supply.

And if that water is charged with sewage, such water must be infected therewith.

If a large supply is pumped from wells so situated, it will facilitate the contamination.

Two of the Kent company's wells have been discontinued on this ground.

The pollution would take time.

*Baldwin Latham*, 7944 to 7975.—In his judgment, the discharge of the sewage is likely to affect the wells in the neighbourhood.

Levels of all the wells at Grays were taken, and it was found that from the pumping which was going on, the water fell, and there was a direct flow from the direction of the Thames (which at that point has received the Metropolitan sewage) towards the spot.

Waters from wells in the neighbourhood have been analyzed and found to contain very much more chlorine than when the pumping was not going on. The quantity of chlorine varies with the state of the tide, there being a somewhat larger quantity at high than at low water.

Judging by the chlorine analyses it is inferred that on an average 23 gallons of river water are mixed with 1,000 gallons of the normal water of the district. One well shows 25 in 1,000.

120. The answer of the respondents is (*Law* 13,962–5) to the effect that the supply to such wells will be from the land, and not from the river;—that the water will run from the wells into the river, and not from the river into the wells.

We do not think this is always the case. As long as the water in the land strata adjacent to the river is undisturbed, it will stand at a level a little higher than that of the river, and so will tend to discharge into it. But when pumping goes on, the immediate effect is to lower the land water level for a considerable distance around, and consequently, under a lengthened action of this kind, there will be a tendency for the river water to enter the well.

It is known that fresh water obtained from wells in spits or banks of sand surrounded by salt water, or generally from land close adjacent to the sea, becomes brackish if the pumping from such wells is enough to lower the water considerably.

The Kent Water Company still draw water for the supply of the south-eastern districts of London from two wells at Charlton and three at Deptford, all within a short distance of the Thames. When they are pumping, the level of the water in these wells stands about 45 feet below mean tide level in the Thames,* and hence it appears possible that the river water, with any soluble impurity it may contain, might penetrate the permeable strata from which the supplies of those wells are drawn.

At the same time there is no evidence of any actual injury to health or property having arisen from this cause.

---

## (E.)

### The Formation of Shoals or Banks which might prejudice the Navigation of the River.

121. It is right to say that no complaint has been made before us on this ground. The Conservators of the Thames, who would be the proper complainants, have offered no evidence tending to show that any such shoals are at present in existence. But as fears on the subject are very natural, and as it is notorious that they have existed, and still exist, we do not feel justified in passing the matter over without observation.

122. In our historical notice we have already mentioned that two previous inquiries have taken place, in each of which this subject has formed an important feature.

In the Barking Inquiry, 1868, Mr. Rawlinson reported that the main channel of the Thames had not been reduced in depth of water by the detritus in the sewage; but he accompanied this judgment by remarks which showed that he considered there might be reasonable apprehension on the matter if the sewage continued to be discharged in its crude state.

123. The second inquiry, or, as it is usually called, the Mudbank Arbitration of 1879–80, has been especially and emphatically pressed on our notice by the Metropolitan Board, who appear to be under the impression that the decision given in that case must, for all time, absolve them from any liability to a charge of causing evils of the kind we are now considering.

---

* Report of Royal Commission on Water Supply, 1869, par. 122.

As we have said, we have no evidence on which to form an opinion of our own on this subject. But assuming that the question is not a practical one at this moment, we should not like to say it never can become so.

The inquiry was confined to three particular banks, which had grown up within the last few years, and the decision was to the effect that these banks had arisen from the effect of dredging operations. The arbitrators called attention to a natural law in the phenomena of rivers, namely, that when the current was slackened by an enlargement of the sectional area, there was a tendency to the deposit of any solid matter held in suspension in the water; and as it was shown that dredging operations had been carried on to such an extent as to enlarge the areas at the places mentioned, the deposit of shoals followed as a matter of course.

124. But there is nothing in the grounds of this decision to render it impossible or improbable that the sewage discharge may, at some time, contribute materially to the formation of shoals in the river.

Experience shows that owing to the great irregularities in the movements of the water in tidal estuaries, the natural action may be powerless to maintain the channel unless aided by artificial measures; and there is no reason for considering the Thames as any exception to this rule.

When therefore it is considered that the sewage discharge, according to Dr. Frankland, adds to the river no less than a million and a quarter tons of mud every year (enough to fill up 300 yards of the river near the outfalls to low water level), it cannot be unreasonable that some alarm should be felt at the continuance of the process.

## CONCLUSIONS.

125. The following is a summary of the general conclusions we have arrived at in regard to the first two subjects of our inquiry.

1. That the works of the Metropolitan Board, for the purpose of carrying the sewage of London to the respective outfalls at Barking Creek and Crossness, have been executed in a highly creditable manner, and have been of great benefit to the metropolis. — Execution of works.

2. That the storm overflows allow the occasional discharge, into the river within the metropolis, of considerable quantities of solid fæcal matter accumulated in some of the sewers; but this has not caused, under present circumstances, serious damage or offence. — Storm overflows.

3. That the sewage from the northern outfall is discharged partly over the foreshore, and not, as was originally intended, "through submerged pipes terminating below low-water mark;" this arrangement increasing the risk of nuisance from the discharge. — Discharge from northern outfall.

4. That the discharge of the sewage in its crude state, during the whole year, without any attempt to render it less offensive by separating the solids or otherwise, is at variance with the original intention, and with the understanding in Parliament when the Act of 1858 was passed. — Crude state of the sewage.

5. That the discharge from the main outfalls becomes very widely distributed, by the motions of the water, both up and down the river, being traced, in dry seasons, through the metropolis, and almost as high as Teddington. And that it oscillates for a long period before getting finally out to sea. — Distribution of the sewage.

6. That the dilution of the sewage by the land and sea water, aided by the agitation produced by the various motions in the river, effects a partial purification of the sewage by oxidation. And that this purification is carried further by the action of animal and vegetable organisms. — Partial purification.

7. That the sewage, which becomes distributed to the higher and to the lower portions of the river, thus gradually loses its offensive properties. The limits, above and below the outfalls, where this purification becomes efficient, vary with the meteorological conditions; but it may be stated that, in general, above Greenwich and below Greenhithe, the river does not afford ground for serious complaint. — Limits where purification efficient.

8. That between these limits the effects of the sewage discharge are more or less apparent at all times. — Offensiveness between these limits.

9. That in dry seasons the dilution of the sewage is scanty and ineffective, especially at neap tides. — Scanty dilution in dry seasons.

10. That it does not appear that hitherto the sewage discharge has had any seriously prejudicial effect on the general healthiness of the neighbouring districts. But that there is evidence of certain evil effects of a minor kind on the health of persons employed on the river; and that there may reasonably be anxiety on the subject for the future. — Effect on health.

11. That in hot and dry weather there is serious nuisance and inconvenience, extending to a considerable distance both below and above the outfalls, from the foul state of the water consequent on the sewage discharge. The smell is very offensive, and the water is at times unusable. — Nuisance and inconvenience.

12. That foul mud, partly composed of sewage matter, accumulates at Erith and elsewhere, and adheres to nets, anchors, and other objects dropped into it. — Foul mud.

13. That sand dredged near the outfalls, which used to be obtained in a pure state, is now found to be so much contaminated with sewage matter as to be unusable; compelling the dredgers to go farther away. — Dredging interests.

14. That for these reasons the river is not, at times, in the state in which such an important highway to a great capital, carrying so large a traffic, ought to be. — River not as it should be.

15. That in consequence of the sewage discharge, fish have disappeared from the Thames for a distance of some fifteen miles below the outfalls, and for a considerable distance above them. — Injury to fish.

16. That there is some evidence that wells in the neighbourhood of the Thames are affected by the water in the river; and, although there is no proof of actual injury due to the sewage, that anxiety may be felt on that point. — Injury to wells.

17. That there is no evidence of any evil results to the navigation of the river, by deposits from the sewage discharge; but that this discharge adds largely to the quantity of detritus in the river, and so must increase the tendency to deposit. — No evil to navigation.

18. That the evils and dangers are likely to increase with the increase of population in the districts drained. — Probable increase.

Remedies.

19. That it is desirable we should inquire further "what measures can be applied for remedying or preventing" the evils and dangers resulting from the sewage discharge.

Time for consideration.

20. That before we proceed to this further branch of our inquiry, we should allow some time for the consideration of this our First Report, and of the remedies which may be suggested for the evils we have pointed out.

All which we humbly certify to your Majesty, under our hands and seals.

BRAMWELL.
JOHN COODE.
C. B. EWART.
ALEX. W. WILLIAMSON.
F. S. B. F. DE CHAUMONT.
THOMAS STEVENSON.
JAMES ABERNETHY.

WILLIAM POLE, *Secretary.*
31 *January* 1884.

This Report is not signed by our colleague, Sir P. Benson Maxwell, who is absent from England on public duty. But the substance has been discussed with him, and he has written us the following letter:

DEAR SIR, November 27, 1883.

YOU are aware that owing to my absence in Egypt I did not hear the evidence on behalf of the Metropolitan Board or the observations of their Counsel. I afterwards read both, however; and assisted in the preparation of the Report about to be presented.

As again I am obliged to absent myself I shall be glad if my colleagues of the Thames Sewage Commission will express for me my entire concurrence in the Report.

Very truly yours,
P. BENSON MAXWELL.

Dr. Pole,
Secretary to Thames Sewage Commission.

# MINUTES OF EVIDENCE

TAKEN BEFORE

# THE ROYAL COMMISSION ON METROPOLITAN SEWAGE DISCHARGE

AT THE

## House of Commons Committee Room, No. 11.

## FIRST DAY.

**Thursday, 27th July 1882.**

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
PROF. ALEXANDER WM. WILLIAMSON, PH.D., F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.
WM. POLE, Esq., F.R.S., *Secretary*.

Mr. WEBSTER, Q.C., Mr. LUMLEY SMITH, and Mr. BALFOUR BROWNE appeared as Counsel on behalf of the Corporation of the City of London, instructed by Sir THOMAS NELSON.

Mr. BIDDER, Q.C., Mr. MICHAEL, Q.C., and Mr. NORMAN BAZALGETTE appeared as Counsel on behalf of the Metropolitan Board of Works, instructed by Mr. REGINALD WARD.

Mr. BEAUMONT MORICE appeared as Counsel on behalf of the General Committee for the Protection of the Lower Thames from Sewage Pollution, and other local authorities and bodies, instructed by Messrs. NEWMAN, STRETTON, and HILLIARD; also on behalf of the Erith Local Board, instructed by Mr. PARISH.

Sir JOSEPH WILLIAM BAZALGETTE, C.B., called in and examined.

*Sir J. W. Bazalgette, C.B.*

27 July 1882.

1. (*Chairman.*) Perhaps the shorter way would be for you to make your own statement first, and upon that we can ask you any question?—Before I begin to describe the works which we have carried out for the interception of sewage from the river, I would like to refer shortly to what has rendered those works necessary. The Thames is situated in the bottom of the London basin, Highgate and Hampstead forming the rim of the basin upon the north, the rim upon the south side being somewhat further distant, namely, the Surrey hills. Into that basin the rain water flows from those hills through riverlets and brooks down to the Thames. In the first place upon the north side there is the Eel Brook, then the Ranelagh, the Stamford Brook, and the Brook Green Sewer. I am not going through all of them, but will take a few of the leading ones. Then there are the King's Scholars' Pond, the Fleet, the London Bridge Sewer, the Irongate Sewer, and the Ratcliffe Highway Sewer. Now these are all streams which flow from that high ground into the Thames.

2. You have some upon the other side also; will you mention those?—Yes, we have some upon the other side. I should mention the Falcon Brook, the Effra, the Duffield, the Earl, and Great St. John's.

3. And the Ravensbourne; does that also flow into the Thames?—The Ravensbourne River is also now converted into a sewer by Act of Parliament. These riverlets flowed from the high ground down into the low ground, which is considerably below the level of high water; and therefore when the tide was up, (and at one time the tide flowed all over that low ground, but it has since been embanked), and when it flowed up these streams, in times of heavy rain these riverlets overflowed the low ground. At that time before the general introduction of waterclosets, the sewage went into cesspools, and it continued to do so until it was found that the introduction of waterclosets rendered that almost impossible. Then overflows from these cesspools into the sewers were for the first time permitted. I should mention that when those sewers were brooks, at first it was penal to discharge any sewage into them; but it was found necessary then that a change should take place. Eventually it was found that the cesspools were sources of disease. They had become so numerous that when one cesspool was filled, instead of emptying it persons would fill it up and have another, and many houses had two or three cesspools under them, which gave rise to disease. Then about the year 1847 that was found to be so inconvenient that it became the law that everyone should drain his house into the sewer, and at that time there were some 30,000 cesspools destroyed, the houses being connected with the sewers. Then these open sewers had to be covered and were carried as covered sewers into the river. They discharged, passing through this low ground, at the level of low water, so that they discharged their contents into the river at the worst period as far as the sanitary condition of the river was concerned; firstly, because the sectional area of the river at low water is very much smaller than at high water, and secondly because instead of being carried by the ebb tide away from London the sewage was carried from low water to high water up the river. I have prepared a section of the Thames at London Bridge to show you the difference between the sectional area of the water at high water and at low water. The blue colour represents the water in the river at London Bridge at low water, and the upper line

*Sir J. W. Bazalgette, C.B.*

27 July 1882.

represents high water at Trinity, the high water being about four times or rather more than four times the low water area.

4. (*Mr. Michael.*) Then you have another line drawn which represents the Ordnance datum between the two?—I have.

5. (*Chairman.*) Will you hand that in?—I will, (*handing in the same. See Appendix A.*) Now putting a floating body into the river at high water as compared with low water makes really a difference of about 12 miles; that is to say if I put a float into the river 12 miles lower down below high water, it will have flowed up that 12 miles and will be in the same condition as if it had been put into the water 12 miles higher up at high water.

6. (*Chairman.*) Is that so, taking 12 miles above London Bridge?—No, I should say not 12 miles above London Bridge, because at 12 miles above London Bridge you get out of the tidal influence, but I am now speaking of from London downwards.

7. (*Sir J. Coode.*) Where do you assume the floats to be put?—I will assume somewhere opposite to London. Putting a float in 12 miles below London Bridge it will float up to London Bridge.

8. (*Chairman.*) Upon an average of tides?—Yes, upon an average of tides. The sewage, therefore, having been put for some years into the river at low water and flowing up, caused a nuisance to the river, which led to the formation of the Metropolitan Board of Works, in order to divert that sewage from the river. It was, I think, about the year 1855 that it was formed, and the first duty the board had to do was to consider how they could overcome this difficulty. Their difficulty was very greatly increased from the fact that, whilst the sewage was of a comparatively small quantity, and a tolerably uniform quantity, the rainfall was a very excessive quantity, and a very variable quantity; the rainfall at times in a thunderstorm amounts to an inch in an hour, and sometimes even to 2 and 3 inches, and we have had as much as 4 inches in an hour over parts of London. Now the maximum flow of the whole sewage of London does not amount to $\frac{1}{100}$th of an inch per hour in quantity.

9. Is that over the entire area?—Yes, over the entire area. The question, therefore, was how to deal with this variable quantity; a very great difficulty it always has been, and still continues to be. One proposal, and it is a plan which has been carried out in rural districts with success, was to separate the sewage from the rainfall, but in dealing with London that appears to be hardly practicable. There are 400,000 houses in London, and the adoption of such a plan would involve re-draining every one of those houses. You must put a drain into the house to take the sewage from the waterclosets and from the sinks, in fact, from the inside of the house; and you must carry the water from the roofs by another drain, separating the two from each house from the very commencement. Now, putting that reconstruction of all the drains of all the houses in London at 20*l.* per house upon the average, would make 8,000,000*l.* to begin with in the house drainage. Then it is not merely a question of money, but I think you would have a very powerful resistance to any such proposal. I think that every house in London having to be re-drained would, both on account of the expense and of the immense disturbance that would arise from it, be a proposal which would be very strongly objected to. Then that is not all. You would have to use the present system of sewers for the storm water, and to lay an entirely separate set of sewers through the streest for the sewage, with pumping establishments, and so forth. That we came to the conclusion could not be done; that, as it applied to London, it was an impracticable suggestion. Therefore we began to consider what the condition of the rainfall was, and it appeared from tables of rainfall that there were only from 14 to 21 days in the year on which the rainfall excedeed the rate of a quarter of an inch in 24 hours; therefore we said, if we can divert the sewage from the river in dry weather altogether on all those days excepting the 14 to 21 according to the season (a very wet season has been 30 days), we shall sufficiently divert the sewage from the river to make it clear; and that was the principle upon which we started, determining to divert from the present sewers which discharged into the river the whole of the sewage and a quantity equal to a quarter of an inch of rain running off with it. That was done by constructing lines of sewers at right angles or nearly so to this main valley sewer, which ran from the high ground down into the river, and we began by intercepting it at the upper points, so as to carry the sewage as much as possible to high water by gravitation in order to save pumping. In that way we commenced by constructing what we called the High Level Sewer upon the north side of the river, commencing at Highgate and Hampstead, passing down by the old Hackney Brook sewer, through Hackney and Stratford, over the River Lea, and by an embankment over the railways, down to Barking Creek. That goes past the pumping station, and is not affected by it. That sewer intercepts the sewage from an area of about 10 square miles. It commences by being 4 feet in diameter and is increased at the lower end, near the River Lea, to 9 feet 6 inches by 12 feet. Its fall at the upper end is 75 feet to the mile, and at the lower end 4 feet to the mile. Its length is about 7 miles.

10. Does it take anything from below it at all?—No.

11. There is not slope enough to take anything from below it, is there?—Yes it is deep enough to take in a little upon the south side of it. Perhaps I should explain here, that the sizes of the intercepting sewers being graduated to take the calculated quantity, that is to say, the sewage and the quarter of an inch of rain, whenever they are filled; near the top of them is a long weir, and the surplus water, when the rain exceeds the normal quantity, flows over this weir into the main sewer at a lower point. It runs from the main sewer (take the King's Scholars Pond Sewer, for instance), into the intercepting sewer, and then when that intercepting sewer is filled near to the top of the sewer, the weir, which is passed along the side of the sewer, allows the surplus to overflow, and it is carried by a branch into the lower part of the King's Scholars Pond Sewer. That is the principle upon which the storm waters are allowed to pass from the intercepting sewers down into the river.

12. It does not find its way into that main sewer again but into the sewer below it, is that so?—No, it goes into the sewer from which it has come.

13. And then discharges itself?—That is again intercepted by another intercepting sewer, and when it is filled the overflow again passes from it, and ultimately arrives at the river at the storm outlet. The Middle Level Sewer commences at Kensal Green, passing through Oxford Street, and nearly in a direct line down to the High Level Sewer near the River Lea, at Bow, and then the two unite, or are carried by two parallel sewers down to the outfall.

14. (*Sir J. Coode.*) They are quite distinct from each other after they join; they are two sewers parallel with each other, but distinct?—They are parallel, but at the same time having the means of communicating with each other, and so equalising the flow at the outfall.

15. (*Dr. Williamson.*) If you desire it, but ordinarily there is no communication?—No, the Low Level Sewer commences at the pumping station and passes at Pimlico along the Victoria Embankment, along the banks of the river, through the City, through Stepney, underneath the River Lea to the pumping station at Abbey Mills. I will describe the pumping stations together when I come to them. There it is lifted to the level of the High and Middle Level Sewers, and the three pass by three parallel sewers down to the reservoir at Barking. The Middle Level Sewer is 4 ft. 6 in. by 3 feet at the upper end, and increases to 10 ft. 6 in. in diameter at the lower end; its inclination varies from 17½ ft. in a mile down to a

minimum of 2 feet in a mile; the length of that is 11½ miles. The Low Level Sewer drains an area of about 11 square miles, it is 6 ft. 9 in. diameter at the upper end, 10 ft. 6 in. at the lower end, and its inclination varies from 3 feet to 2 feet per mile; it is 12½ miles long. Then there is the area beyond, containing Chelsea, Hammersmith, and Acton, which is at a low level, and that is termed the western division; it has a separate set of sewers passing through Chelsea from Hammersmith with a pumping station at Pimlico. There the sewage is lifted into the Low Level Sewer, and passes thence to the outfall through it. Upon the south side there is also a high level sewer with a southern branch, the Effra branch.

16. (*Chairman.*) Upon the north side, I may ask you whether anything to the westward of your system of sewers still finds its way to the Thames?—The pink line upon the cartoon represents the area of the metropolis.*

17. (*Sir J. Coode.*) That is the area for which the Metropolitan Board of Works are obliged to provide?—I should have stated that the Metropolitan Board of Works, constituted under the Act of 1855, had to intercept the sewage from the Thames, of a given area which is defined by the Act, and that area is represented by the pink colour upon the map.

18. (*Chairman.*) That is to say the pink lines?—Yes.

19. (*Sir J. Coode.*) North and south?—Yes, it contains 117 square miles. The whole of those works are laid out with regard to that area and nothing beyond it. The High Level upon the south side has a main line, and a high level branch which, together, intercept the sewage from 20 square miles. The route of those sewers is this; a branch commences at Dulwich, passes down to Peckham, and then to Deptford Creek, the main line commencing at Clapham, passing down through Brixton into the same creek. They pass under the creek by iron pipes and have an overflow for storm water into the creek, that is to say they are large sewers coming down to the creek, and at the creek they pass, with a grating at the bottom of them, through iron pipes into the outfall sewer; but when in times of storm that quantity is exceeded it rises up in pipes under pressure and opens some flaps into the creek, and the storm waters are thus discharged into the creek.

20. (*Chairman.*) It differs then, as I understand you, from what is upon the north side in this particular, that the storm water is not discharged into the intercepting sewer upon the other side of the interception, is it?—Yes, it is so in both.

21. And in addition, you have this contrivance at Deptford Creek?—Yes; and I should say that we have the same upon the River Lea for the Northern Outfall Sewer.

22. (*Sir J. Coode.*) How many storm discharges have you to the westward of Deptford upon the south side of the river?—Eleven. I will give you them in detail. Now the Southern High Level Sewer varies from 4 feet 6 in. by 3 feet, to two parallel sewers, each of them 10 feet 6 in. high and 10 feet 6 in. wide, with upright sides and a crown; the inclination varies from 30 to 2⅓ feet per mile, and the length is 13 miles. The Low Level Sewer on the south side commences at Putney, passes through Wandsworth, Battersea, Nine Elms, and Kennington, down to Depford Creek. The whole of the area between the Low Level Sewer and the river is exceedingly flat, and the sewer is very flat, and that is the reason why it is not carried along the margin of the river as is the Low Level Sewer upon the north side. The outfall sewer is 11 feet 6 in. in diameter, with a fall of 2 feet per mile. Now the pumping stations are, one at Crossness at the outfall upon the southern side with a lift from 22 to 33 feet, varying according to the state of the tide and the condition of the sewage, with a 500 horse-power pump and an auxiliary pump of another 500 horse-power used in time of storm. At Deptford Creek there is a lift from the Low Level Sewer into the outfall sewer of 18 feet, with engines amounting to 500 horse-power. At the banks of the Effra there is 200 horse-power provided for lifting the storm waters into the river in times of heavy storms, when they are penned up by the tide, and another at the Falcon Brook of the same power, which lifts varying from 6 to 12 feet. At Abbey Mills the lift from the Low Level Sewer into the outfall sewer is 36 feet, and the horse power provided is 1,140 horse-power. The western division is lifted into the Low Level Sewer 18 feet, with 360 horse-power, and an auxiliary of 120 in times of heavy rain. Althgether there are 3,520 horse-power.

23. That is to say nominal horse-power?—Yes.

24. Not indicated horse-power?—No, nominal horse-power. For the discharge of storm water into the river there are 35 outlets upon the north side, and 12 on the south. I have a list of them showing the sizes of each and the levels; but I may state that inasmuch as the levels of these storm outlets are so low, still, in times of heavy rain at high water when the outlets cannot discharge into the river the low districts are at times subject to floods. There have been serious complaints at Pimlico and at Battersea, where the surface of the ground is 5 or 6 feet below the level of high water, where some of the houses have basements, and the sewers are below those basements, that at the time of high water in a heavy flood they get overcharged, and the water rises into the basements.

25. You are speaking of the rising of fresh water?—Of the overflow of the sewers dammed up by the tide.

26. But the flooding is by fresh water, country water?—Yes. In order to get over that difficulty the Board of Works have determined to expend over a million and a half of money in constructing storm relief sewers. One of such sewers has been constructed in the Fleet Valley, upon the principle of making them perfectly water tight, having no communication with the low districts whatever; and acting as pipes under pressure. Those sewers go into the river 8, 9, or 10 feet in diameter. They have no connexion with the districts through which they pass, they are carried through the low districts up to higher ground, and then the storm waters which are poured into them charge them full until the waters rise to a higher level than the water in the river. Then that height of water upon them immediately creates a pressure and a discharge into the river.

27. (*Chairman.*) That is the intention?—That is the way in which they are designed.

28. It is not done yet, is it?—Yes, it is done in the Fleet Valley.

29. The effect of it is that you have a water-tight pipe, and the pressure of water at the upper end of it forces the discharge into the river?—Yes.

30. (*Sir. J. Coode.*) It overrides the tide as it were?—Yes; it has been done for some years in the Fleet Valley with very satisfactory results, and it is now being done at Vauxhall Bridge, where an enlarged storm outlet is being formed; one of them is being carried up through the low ground towards Clapham, and others are to follow.

31. (*Dr. Williamson.*) I understand that will provide only for the storm waters of the higher level of the basin?—Yes; At present the storm waters from the high level of the basin pour down to the lower part of the basin, and the water rises and floods the houses, the sewers being insufficient to carry it off. Now the proposal is to let the sewer in the basin carry off the water of its own district, but to let the storm outlets take into the river the storm water from the higher districts.

32. (*Sir J. Coode.*) The object being to relieve the lower lying districts from the pressure of storm water from the higher districts?—Yes.

33. (*Chairman.*) Then we neither send more nor less sewage into the river than goes there now?—Neither more nor less, it is to prevent that sewage

* The essential features of the cartoon referred to by this witness have been reproduced in the map, Appendix B.

*Sir J. W. Bazalgette, C.B.*

27 July 1882.

from being held underneath the houses and discharged at low water, and to enable it to go into the river at high water.

34. It will prevent the low districts being flooded with sewage and flood water mixed, and will send it into the river at once instead of allowing it slowly to soak into the river as it were?—Yes, that is the sole object of these sewers. I do not know whether I have sufficiently described the works of the intercepting sewers.

35. (*Chairman,*) Speaking for myself, I can only say nothing can be plainer.

36. (*Mr. Michael.*) Would you very shortly point out to the Commissioners the main sewers which are held under the Metropolitan Acts, in order that the Commissioners may have a conception of how the sewage gets into the main sewers?—The main sewers are those which I have been describing as the Ranelagh, the King's Scholars' Pond, and the Fleet, which run from north to south into the river, and which are intercepted by intercepting sewers.

37. Those are also under the Metropolitan Acts vested in the Metropolitan Board of Works, and are a portion of your system of sewerage?—They are. Perhaps I should explain that whilst the Metropolitan Board——.

38. (*Chairman.*) It would perhaps meet Mr. Michael's view if you would tell us what becomes of the sewage of any particular house?—It falls through its own pipes into the sewer of the street opposite to it, which is probably a district sewer.

39. Not belonging to you?—Not belonging to the Metropolitan Board of Works. I may explain that the Metropolitan Board of Works under the Act of 1855 has the charge of the main intercepting sewers which I have just described, and also of the main storm sewers called main sewers of Schedule D in that Act, certain sewers which are named. The district boards, some 40 in number, have charge of the branch sewers under the general control of the Metropolitan Board of Works. I should have stated that, in addition to the outfalls which I have referred to, there are still some few small sewers discharging into the Thames. We began to divert all those small sewers and drains upon the banks of the Thames, (any drain draining more than one house is called a sewer) to pick up the small sewers along the margin of the river, and divert them into the main intercepting sewers; but we were advised some three years ago that it was the primary duty of the district boards to deal with the small sewers, therefore we have served notice upon the district boards to divert the small drains into the intercepting sewers. To what extent that has been carried out I am unable to say at present.

40. Now I will ask you a question by way of illustration. Upon this south side of the river there may be some sewer falling into the Thames, as I understand, instead of falling into your intercepting sewer?—There are some houses upon the margin of the Thames having what really are drains, but which are technically sewers, passing still into the Thames. Now the outfall sewers all discharge into reservoirs, one at Barking and one at Crossness, the time of discharge commencing at high water, and continuing for four hours after high water. And I may say that the reason which induced the Metropolitan Board of Works to select those two points was, first, that on the north side of the river Barking could be reached by a large portion of the metropolis at high water by gravitation, and so reduce the pumping; and, secondly, because between Woolwich and Erith there is a length of six miles of river with nothing upon its banks but bone factories, artificial manure factories, glue factories, and works of an offensive character. There is no habitation to speak of upon that six miles, and there is no other point upon the river, until you get below Gravesend, where the same can be said of its banks. If you go below Erith you have Greenhithe, Purfleet, Grays, and Northfleet; and therefore to get as eligible a position as Barking and Crossness for the discharge of the sewage, it would be necessary to go below Gravesend, at least 15 miles lower down than we are now.

41. Now it may excite a smile, because it is manifest—anybody may make this observation,—you were going to commit a nuisance, and therefore you thought you would make it as little as possible; it is very unkind I know to say so?—No doubt that can be said, but the discharge of the sewage into the river was necessary, and it was a question where it should be discharged. Now if you are to discharge it 15 miles lower down, the least fall you could give to your sewer would be 2 feet in a mile; that means a depression of 30 feet for that 15 miles. A depression of 30 feet means lifting the sewage 30 feet. It also means that if you carry your sewer down below the bed of the river you can never discharge that sewer, in the event of the pumps breaking down, by gravitation; it can only be emptied at all by being pumped, and I estimate roundly that the cost of carrying two such sewers as we have for our southern outfall sewer for 15 miles, and lifting the sewage to the same height as it is discharged at Barking, would be at least 2,500,000*l.*

42. Including land?—Yes, including a small estimate for the land.

43. I suppose you would have to pay for the land?—We should have to a large extent to pay for land.

44. Could you do it for that?—I do not know that we could do it for that; it would be at least that, at any rate.

45. It is almost all hills upon the south side to Gravesend, sand hills first, and chalk hills afterwards?—I do not give this as an exact estimate. I have taken as a basis the cost of constructing the sewer through Plumstead Marshes, which was about 40,000*l.* per mile; and I say the continuation of the necessary intercepting sewers for both sides of the river, for 15 miles, would cost from 2,500,000*l.* to 3,000,000*l.*, with the requisite engines, buildings, and reservoirs.

46. And the expense of the pumping?—The expense of the pumping would be about 50,000*l.* a year, which, capitalised, would represent about 1,000,000*l.* and which is not included in the foregoing figures.

47. (*Mr. Michael.*) I do not think you have given the quantity of sewage you deal with on both sides of the river?—I am going to do that.

48. (*Chairman.*) What was the cost of the works generally which you proposed?—About 4,000,000*l.*

49. (*Sir J. Coode.*) That applies to the sewer works shown in red upon that map, and the subsidiary works, the system now in operation?—Yes, the system now in operation.

50. (*Mr. Michael.*) That is exclusive of all sewers belonging to the district authorities?—Yes, that applies to the main intercepting sewers; nothing that has been done to the Schedule D. sewers.

51. (*Mr. Abernethy.*) Not to the storm water sewers?—No; the 1,500,000*l.* that I mentioned would be in addition to that.

52. (*Chairman.*) Upon the Essex side it is marsh almost all the way down the banks of the river to Gravesend, except that at Grays or at Purfleet there is a little bit of hill?—That is so.

53. However, you have estimated the cost of carrying the outfall further down at 2,500,000*l.*?—I did not give that as an estimate, but rather as an idea.

54. You consider it would cost at least that?—Yes. Here is a map which will show Barking, Crossness, Woolwich, Erith, Purfleet, Grays, Thurrock, and Greenhithe (*handing in the same.*) That map shows a private scheme which was proposed some time ago for taking a portion of the sewage down the river and irrigating land with it.

55. (*Sir J. Coode.*) Fifteen miles lower down the river would bring you to what point?—To Tilbury Marsh, upon the north side, and the Mucking Flats upon the south. Now, in order to discharge the sewage at high water, and to take advantage of the ebb tides for carrying it away, we have constructed reser-

voirs, a reservoir at Barking covering about 9½ acres, and a reservoir at Crossness covering about 6½ acres.

56. (*Dr. Williamson.*) Of what depth?—I will give you the whole of the figures. Barking is about 11½ miles below London Bridge, and Crossness is nearly 13½ miles, or 2 miles lower down. I am going to give some of the levels in a little detail, because, I think, probably, the engineers upon the other side will want to know them, and it is as well to give them in the first instance. Trinity high water is 12 feet 5 in. above Ordnance datum; low water is 7 feet 6 in. below datum.

57. (*Chairman.*) Therefore there is a difference of about 20 feet?—Yes. I am taking an ordinary spring tide, a tide represented by Trinity high-water mark, which is not a high spring tide, but a moderate spring tide; therefore, half tide is + 1·56 — plus means over datum, minus means below. The bottom of the reservoir is + 2·75 feet or 1·19 feet above half tide; the bottom of the reservoir is therefore a little over one foot above half tide, that is at Crossness and Barking. These reservoirs, I should explain, are brick arched, covered over, and they have weirs at the height I give, so that when they are full there should be an overflow from them. The overflow weirs at Barking are 16·25 feet, or 3·75 above Trinity high water; the available depth, therefore, is 13½ feet. The overflow weirs at Crossness are 2·5 higher than at Barking, and the available depth at Crossness is 16 feet. The invert level of the northern outfall sewers where they come down to the Barking reservoir is + 11·4, so that the overflow weirs are nearly level with the mid height of the outfall sewers. The reservoir will begin to overflow when the sewer is running half full, it would rise up or be ponded up to half the level of the sewer; beyond that it would go off. Barking reservoir will contain 35,000,000 of gallons, or 5,600,000 cubic feet. Crossness reservoir contains 25,000,000 gallons, or 4,000,000 cubic feet, making together 9,600,000 cubic feet. Now, in 1878, the quantity discharged at Barking altogether, including rain, in 24 hours, was 13,120,000 cubic feet, which in the eight hours that the reservoir has to store it, would amount to 4,373,000 cubic feet.

58. (*Dr. Williamson.*) Is that in the course of the day?—No, in one tide; there are two tides of 12 hours. Now, if we are discharging only from high water for four hours, we must be storing for the remaining eight hours.

59. And if you are storing during that time you are emptying also, are you not?—No, we are storing then.

60. You must be, unless you have two reservoirs?—It is flowing into the river for four hours.

61. But it is flowing into your reservoir at that time too?—It is flowing through the reservoir.

62. But it is discharging more than has accumulated in eight hours?—Yes, it is discharging what has accumulated during the other four hours of that time.

63. (*Sir J. Coode.*) When you say, "including rain," what do you assume?—I am taking the average of the quantity that came down for the year 1878.

64. That is to say the yearly average?—Yes; so that we had at Barking to store 4,373,000 cubic feet. At Crossness the average sewage and rainfall discharge was 12,164,000 cubic feet, giving for eight hours' storage 4,055,000 cubic feet, equal to a total of 8,428,000 cubic feet from the two reservoirs in the eight hours. I have just stated that the storage capacity of the reservoirs was 9,600,000 cubic feet, so that we had a little margin there; but I have not got the actual quantity since 1878, but it appears that in the four years before 1878 the average increase was 14 per cent.; therefore I have taken four years since 1878, and assumed that the increase has been as great, although I do not think it has been quite so much, for the year 1878 was a very wet year; however, I have taken it out and reasoned upon that assumption.

65. You say "the daily average over the year," then do you take the total annual rainfall and assume that to be distributed equally over the whole 365 days?—No, we have measured the quantity actually coming down.

66. But that is the average over the whole year?—Yes.

67. What was the maximum is the question we have rather to deal with than the average.

67*a*. (*Mr. Abernethy.*) Is that exclusive of what flows over the storm weirs?—No, that takes in the storm weirs.

68. (*Sir J. Coode.*) When you give us the average, it does not show what the maximum would be?—It does not.

69. (*Chairman.*) You say you discharge from these reservoirs for four hours?—Yes.

70. Can you empty them?—Yes, they are quite empty at every tide, the bottom of them is above the level of half tide. When the tide has fallen half way it is below the bottom of the reservoir, the sewage is stopped up much above high water, so that the moment the sluices are open at high water there is a rapid discharge down to the level of high water.

(*Sir J. Coode.*) What the noble chairman is trying to arrive at, if he will allow me to say so, is this, the relative area of the sewer as it enters the reservoirs and the discharging power of the reservoir itself.

71. (*Chairman.*) You have said that with the exception of the average of about 21 days in the year your sewers are so constructed as to take off the rain water and the sewage. I suppose you arrange your reservoirs in such a way as that they should be capable of receiving what the sewers are so capable of discharging?—No, that is not so, the sewers are capable of bringing much more than the reservoirs will hold; and when they are doing so there will be an overflow of the reservoirs just as there is an overflow at all the storm outlets.

72. Direct into the river?—Yes, we say that if storm overflows must be permitted in London itself, much less objectionable it would be to have storm overflows at Barking and Crossness, the lower down the river you can get them the better.

73. (*Chairman.*) It comes to this, that you may have an overflow at your reservoirs at the beginning of flood tide?—I am going to give you more information about that to show you what we propose to do.

74. But it is so, is it not?—As a fact on 43 days in the beginning of 1881 there were overflows from Crossness Reservoir at the time of flood tide. I have not the return from Barking, but I believe there were more days at Barking than at Crossness.

75. But it might be that sometimes your sewers would carry off all the rainfall, but your reservoir could not hold it, and then it comes up the river with the flood tide?—Yes. Now I was going on to argue that, supposing the increase in the quantity of sewage had gone on since 1878 as it did in the previous four years, we should have the quantities increased to the amounts that I gave. We should have now the quantity at Barking of 14,956,000 cubic feet, or in eight hours 4,985,000, and upon the south side we should have 13,867,000 cubic feet, and in the eight hours 4,622,000, or a total of 9,607,000 cubic feet. Now your Lordship will see that on the average that just balances what our reservoirs are capable of holding, and, as the flow is not even our reservoirs may be overcharged, and are overcharged at times even in dry weather.

76. How is that, supposing it has not rained for a fortnight for instance, could that occur?—Yes, it does occur sometimes even without rain; because in the middle of the day the flow of the sewage is greater than it is at night, or greater than the average flow, and, therefore, we sometimes get an excess and it overcharges our reservoirs. Now we had foreseen that difficulty, and the Board of Works were determined to enlarge their reservoirs to the amount of 50 per cent; that order was given some time ago. Contract drawings had been prepared, and they would

*Sir J. W. Bazalgette, C.B.*

27 July 1882.

have been enlarged at a cost of 160,000*l.*; but objections to the position of the outfalls having been raised, it was said, "This Commission may object to your outfalls altogether; it may object to your spending more money at those outfalls"; therefore the Board of Works have adjourned the construction of these additional sewers for three months, in deference to this Commission. The mean flow of the fresh water coming down the river is 84,500,000 cubic feet in each ebb tide.

77. Will you explain that a little more fully?—That is the amount of fresh water coming down the river.

78. The average contribution of the river to the sea, you may say?—Yes.

79. Where?—At Barking, for example.

80. (*Sir J. Coode.*) That, again, is the mean over the whole 12 months?—Yes, that is the mean. The discharge of tidal water past the outfall is 2,148,713,000 cubic feet, together making the water that flows down each ebb tide 2,233,213,000.

81. (*Chairman.*) That supposes, if I understand rightly, that the 2,000,000,000 is water which has been up and has come down again?—Yes, tidal water which has flowed up and come down again.

82. It is not up-land water or country water?—The 34,000,000 is the water above the tide, and the tide itself is the two thousand odd millions, together making 2,233,213,000.

83. So the fresh water would be about four per cent.?—Yes, speaking roughly.

84. What is the volume that you discharge at the two places?—14,000,000 for one tide.

85. (*Dr. Stevenson.*) Is the 14,000,000 the north or the south?—Both together. I do not know that I have any further statement to make.

(*Mr. N. Bazalgette.*) Will you explain to the committee for what reason the Board of Works decided upon the Crossness and Barking outfalls, having regard to the tidal action at those two spots.

(*Chairman.*) Sir Joseph Bazalgette told us that one strong reason was that for six miles down the river there were no habitations upon either side, nothing except bone factories and so on.

86. (*Mr. N. Bazalgette.*) Was there any further reason arising from the flow of the ebb and flood tides, will you, in short, explain to the committee what reason the Board of Works had, or what their *ratio decidendi* was, in selecting these two spots: was it in order that the discharge of the sewage at that point should not be carried up to the metropolis but should be taken away by the ebb?—A number of float experiments were made (assuming for the moment the sewage to be a solid block like a float) to ascertain what would be its action if carried down by the river two hours after high water. I will beg leave to read a record of those experiments. "On the 13th of July 1851 a float was put into the centre of the river opposite Barking Creek two hours after high water. This time was chosen because it was found that sewage discharged into the river two hours before high water arrived at about the same point above Barking Creek as sewage discharged two hours after high water did by the next flood tide. At low water the float reached $11\frac{3}{4}$ miles below thst point and returned with the next flood tide to one mile above, it having gone $12\frac{3}{4}$ miles that flood, it being then the period of spring tides. As the neaps came on the float continued to work lower down at each succeeding high water, and by the 24th of July it was 13 miles below Barking Creek at high water, having gone down the river 14 miles during the falling off of spring tides to neap tides. As the floods again became stronger it worked up the river each succeeding tide until the 29th July, when it again came within 5 miles below Barking Creek at high water, having worked up the river 9 miles from high water neap tides to high water spring tides, the excess of the ebbs over the floods being only 5 miles in 14 days. Another experiment was tried at the same place on the 6th of August 1851, it being then lowest neaps, and the float being put down two hours after high water. It worked up each succeeding high water till top springs on the 12th of August, when it reached $6\frac{1}{4}$ miles above Barking Creek at high water. The float then again worked down the river till the 20th of August, $9\frac{1}{2}$ miles below Barking Creek, being a distance of 16 miles during the falling off of spring tides to neap tides. The excess of ebbs over the floods would in this case have been about 7 miles in 14 days. The wind and other causes would vary the result, but it may be roughly assumed that a substance in suspension works up the river about 1 mile a day at each high water as the springs strengthens, and down the river 2 miles a day as they fall of." But of course we say that sewage put into the river would not be like the solid substance which was the subject of that experiment. If it were so, the effect would be when the sewage was discharged at London at low water and went up the river, and then came down again, and at next low water another discharge sent up to join it, and another and another, that you would get in a fortnight's discharge more sewage in the river than there was water, a complete concentration of sewage, in fact. That is, of course, if it remained sewage; and if it had been discharged at low water under these conditions we should have had in London a stream of sewage instead of a stream of water at low water, but for the chemical action which goes on (which will be explained by others better than I can explain it), such as oxidation, which destroys its character to a certain extent.

87. Then will you tell the Commission what the volume of the river is as compared with the volume of sewage discharged into it at the point of discharge?—I have given the figures; you may take it as 150 to 1.

(*Chairman.*) I think I made it out that it was 4 per mil.

88. (*Mr. N. Bazalgette.*) Now, first it becomes diluted and then oxydised, does it not?—I think I had better not speak to that, but will leave it to others who are better informed upon the subject.

89. (*Chairman.*) But I do understand you to say that the solid body, the float, that you put into the water and treated, no doubt, as fairly as you possibly could, when you put it in at the mouth of the sewage discharge (I do not know when it was discharging, but let us say at the dead of the neaps, as they call it) as the springs increased worked up the river about 9 miles?—About a mile a day, on the average.

90. I thought you made it out a little more?—That was so in one instance, but it was on the average up 1 mile and down the next week 2 miles a day.

91. So that, supposing sewage to act like the float that you put into the water, it would have got up about as far as Greenwich?—It would, about that; just about to Greenwich, which is seven miles from Crossness.

(*Mr. L. Smith.*) I would beg leave, instead of putting any questions which would be a criticism upon the system, to suggest some questions upon which we might ask for further information, and then when we have got the information and studied the figures, we might go a littte more into it.

Examined by Mr. Lumley Smith.

92. First of all in regard to the actual area which is drained on both sides of the river; you gave us, I think, the number of square miles which were drained upon the north and on the south, did you not?—Yes, I did.

93. Could you give me again, without trouble, the number of square miles you told us upon the north?—I think upon the north it is 53 square miles, and upon the south 66.

94. Then, in addition to the districts which you

have acquired within the area of the Metropolitan Board of Works, you are acquiring by Act of Parliament the right to drain into your sewers certain other districts, are you not?—No, I think not, when I say that, I should say that there is one exception, a district which was within the metropolis, an island in the metropolis, which, although it did not belong to it, was, by Act of Parliament, made part of the metropolis for drainage purposes, and allowed to drain into our sewer, but Acton and other districts surrounding London have made application to the Metropolitan Board of Works to take their drainage into our system, and that request has been invariably declined upon the ground that the system is laid out to receive the drainage of a given area, and that area cannot be extended.

95. Has not Acton been allowed to drain into the metropolitan system?—No, there are legal proceedings pending at the present time with reference to it.

96. As a matter of fact, does it now drain into the metropolitan system? Does not some sewage now come from Acton into the metropolitan area?—It does.

97. That would increase the number of miles drained?—I do not think it would amount to a square mile.

98. Now with regard to South Hornsey, does not sewage from that district pass into the metropolitan area?—There may be some. Upon the margin there are districts which have the right of sending their surface water into the metropolis, and many of them make use of that right to turn in the sewage of their watercloset; we are using all the vigilance we can to prevent that, nevertheless I am not prepared to say that we have done it entirely; we have been from time to time endeavouring to stop it, and there are legal proceedings pending now.

99. If there were any addition to the sewage which comes from the outside districts, that would increase the quantity discharged. Now you gave us the actual quantity discharged in 1878?—I did.

100. And you were able to tell us that there had been an increase in the 14 years before 1878?—Yes.

101. And up to 1878 there had been a record kept each year of the discharge at Crossness and Barking?—Yes, up to 1878.

102. Has no record been kept since 1878?—Yes.

103. Then why are you not able to give us the actual discharge?—Because it has not been worked up. I have no doubt the materials exist for doing it, but I have not got them.

104. It seems to have been done every year up to 1878?—Yes.

105. So that the actual number of gallons that went into the river from Crossness and Barking was chronicled each year?—Yes, and I can get that; but may I be permitted to say that the main intercepting system was not really completed until 1874.

106. Will you tell me why it was not published year after year after 1878 as it seems to have been published before?—I think the Registrar General has it and can give it to you.

107. Then it is taken out year by year, and we can get at the number of gallons going in at Barking and Crossness?—Yes.

108. Because there has been an increase of building going on, I presume, in those parts of the metropolis?—We send a return to the Registrar-General of the quantities actually discharged at Crossness and Barking.

109. Then you can give the Commission your figures for the years after 1878, instead of basing your returns upon the figures of 1878?—No doubt I could do that.

110. Could you do it without any trouble?—Yes, it may take a little time to get out.

111. Your map shows in red the sewers which are the main intercepting sewers?—Yes.

112. Are those blue lines which have been pointed out the other sewers which existed before the intercepting sewers were made?—Yes they are.

113. Does your map show, in addition, the number of storm overflows into the Thames?—Yes it does. Everyone of the brown circles upon the river represents a storm overflow.

114. Those are all storm overflows; now is any record kept showing how often those are opened?—There is not a record kept as to all of them. I have a record of two of the principal, the one at Deptford Creek, and the one at the River Lea.

115. (*Chairman.*) They are not self-acting then, are they?—Yes they are self-acting. I have a return here of the number of days of overflow from the year 1872 to the year 1879 at Deptford Creek. In 1872 it overflowed 21 days; in 1873, 15 days; in 1874, 9 days; in 1875, 20 days; in 1876, 19 days; in 1877, 30 days, that being a very wet season; in 1878, 17 days; and in 1879, it overflowed 21 days, that of course was not during the whole day, but for part of those days.

116. (*Mr. L. Smith.*) What overflow was that?—Into the Deptford Creek, a large and important storm overflow for the Southern High Level.

117. That is a very important one, is it not—it is where the two sewers seem to meet?—Yes.

118. That is not self-acting, is it, but is opened by hand?—It is self-acting.

119. There are penstocks which are opened by hand and the water is let out, is not that so?—There is a lower flap which is not self-acting which is opened by hand, but when it fills the upper one is self-acting.

120. The bulk of the water comes out through the flap which is opened by hand, does it not?—No, the bulk comes out at the top when the sewer is full; the lower portion is only opened by hand when there is a very excessive storm, because the flaps above are sufficient to carry off the storm water.

121. Could you give us the number of times since 1879 that that has been opened at Deptford?—I have not got that, but I can supply it.

122. Now I will ask you one question as to the way in which the storm overflows act. When the High Level Sewer, as I understand you, gets flooded, it escapes over these weirs into the rectangle sewer?—Yes.

123. (*Chairman.*) But that will not hold it; it escapes over again?—Yes; that takes it from the high level to the middle level, and from the middle level again into the low level.

124. (*Mr. L. Smith.*) From the middle level into the low level, and from the low level into the Thames?—Yes, at low water or near low water.

125. I am speaking of the times of flood when it escapes through the storm overflows?—Yes.

126. It would be mingled water and sewage that would get through these?—Yes.

127. That may happen at any time of the tide?—Yes.

128. And with some of them that are self-acting, as I understand you to say, it would be penned back and the traps would not be lifted up?—They are all self-acting.

129. But can they act at any time of the tide?—No.

130. Are there occasions when they would be penned back?—Yes.

131. (*Mr. Abernethy.*) They would discharge at low water only?—Yes, and that is the reason for our constructing the storm relief sewers which I have described, of which I have a list here.

132. (*Mr. L. Smith.*) The question I am going to put to you is this; the number of gallons which are discharged at Barking and at Crossness would not represent the total quantity that gets into the Thames, you would have to add to that all that goes out of the storm overflows?—At the time of a thunderstorm they may be all of them acting together, but then as regards the admixture of sewage, it would be very highly diluted at those times.

133. At all events that would have to be added to the discharge at Barking and Crossness?—Yes, our great object is to get it into the river as quickly as possible to prevent its flooding houses.

134. (*Chairman.*) You are referring to the storm relief sewers?—Yes.

135. (*Mr. Lumley Smith.*) No record is kept or can be kept of the quantity that goes through the storm relief openings?—No.

136. Are there any pumping stations which are actually kept for the storm water?—Yes.

137. Which are they. I think you said Battersea and Nine Elms?—There are three besides the auxiliary

*Sir J. W. Bazalgette, C.B.*

27 July 1882.

one at Crossness, there is one at the Effra Creek, one at the Falcon, and one at the western pumping station.

138. Where do they pump to?—Into the river, so as to prevent the storm water being held at high water and rising so as to get up to the basements.

139. I suppose when they are pumped into the river the quantity pumped is known at the pumping stations?—That could be arrived at.

140. That would be a figure which could be obtained, showing the quantity which goes into the Thames there?—That would show the quantity pumped, but it would not show anything like the quantity dealt with, because the pumps in stormy weather would only deal with a very small quantity of the total water passing. I have entered into a calculation of what an inch of water over our 119 square miles would amount to, we had at one time rain falling at the rate of 4 inches in an hour.

141. Taking now the actual reservoirs at Barking Creek and at Crossness, you gave us the Trinity high water mark, did you not?—I did.

142. That is not the mean high water mark, is it. Could you give me the mean high water mark?—The mean would be the mean between springs and neaps.

143. It would be rather less, would it not, than your 12 feet?—Yes, it would.

144. I am told that it would be 10·7 feet above Ordnance?—Yes, I dare say it would be.

145. Now with regard to the outfall, can you tell us the actual time at which the sewage is discharged?—From high water to four hours after high water.

146. It begins at high water?—It does.

147. And goes on for four hours after high water?—It does.

148. Then by that time do I understand that the reservoir is empty, or that the operation is stopped?—The reservoir is emptied.

149. And it goes on really till the reservoir is empty, it is not that the servants of the company shut down the penstocks at all, but the process goes on until the reservoir is empty?—The reservoir has been emptied before the four hours are out, and it is flowing through the reservoir.

150. Is it the fact that the reservoir empties itself in that four hours, and that all the sewage which comes down in that four hours is allowed to run into the Thames?—The sewage in the reservoir at high water is higher than high water, therefore when we open the penstocks at high water there is a rapid discharge from the reservoir, it then falls nearly to the level of the tide, it then continues emptying the reservoir as the tide falls until the tide has fallen below the bottom of the reservoir. Then the reservoir is empty, and that in half tide would be about three hours. Then for the next hour it would be running through as it is coming, and then it is closed.

151. Is the practice then to close it?—Yes, the practice is then to close it.

152. Is there any record kept of the time of opening and closing at Barking?—Yes.

153. I am told that sometimes it is seen escaping after the four hours, that it is not actually shut; is that the rule?—I have heard that stated, and it was examined into; it was found that there was some little leakage at one time through one of the penstocks, and that was stopped; but I believe it is regularly attended to.

154. (*Chairman.*) I suppose if there were a considerable quantity of storm water coming down there in a day, so that you knew that if you shut your penstocks the only consequence would be that you would have an overflow, you would probably keep your penstocks open longer?—No, we should shut the penstocks all the same, and should allow the storm overflow to fall into the reservoir until it filled the reservoir, and then it would be above the weir, and pass over the weir and flow into the river.

155. It would be presumptuous in me to differ from you, but it seems to me that this might happen, that instead of continuing to discharge whilst there was a two hours' ebb to go on with, you would lose that two hours' ebb for discharge, and the overflow would not begin until after two hours of flood?—I do not quite understand your Lordship's question.

156. You can tell from the quantity of rain which is falling that there will be an overflow, and that your reservoirs will not hold all that the sewers will bring down?—We could hardly leave that to the judgment of the men who have the care of the penstocks.

157. But assuming this was the case, instead of shutting up your penstocks at two hours before the end of the ebb tide, and waiting for your overflow, which would perhaps begin almost as soon as the flood tide began, I should have thought you had better have taken advantage of the two hours of ebb that still remained?—But the difficulty in doing that would be in leaving it to the discretion of the men, we must have a rule to go by. And then this must be borne in mind, that when you have an excessive storm of this kind all the streams discharging into the Thames are swollen; the Thames itself is swollen, and it is a period when discharging into it is really no nuisance; if there is a nuisance in the river it will be found to be in dry hot weather and not in times of storms. I never heard any complaints at such times.

158. (*Mr. Abernethy.*) I think you stated that during dry seasons there was still very often an overflow?—We have an overflow sometimes in dry seasons, and our reservoirs were to be enlarged to meet that objection; in point of fact the reservoirs when constructed were constructed to last for a certain period, and if necessary to be added to from time to time.

159. (*Mr. L. Smith.*) It has been stated that the discharge was going on after four hours' ebb. I am told that upon the 30th of last June a discharge was found going on at Barking at a quarter past 7 in the evening, which was about six hours after high water?—I was not aware of that.

160. That would be contrary to your practice?—I would ask whether it was dry weather?

161. Upon that particular day I am told it was fine?—I should be inclined to think there was some mistake about that. I can only say our people have very peremptory orders about it; and whenever it has come to my knowledge that it has been let out at any other time I have given them a very severe reprimand. I see no object in anyone connected with the reservoir doing anything of the kind.

(*Chairman.*) I do not think we should report against them for a slip or two.

(*Mr. L. Smith.*) Certainly not; but I am told upon this particular occasion when the sample was taken the outfall was open at a quarter past 7.

(*Witness.*) I have said that our reservoirs are not sufficient now when we have a maximum flow, and I have advised the board to increase them. The only object they have in holding their hand (for the works were ready to be let), was, that it was stated in the public papers, that in the face of this inquiry we should be doing extremely wrong to go and spend the public money on these reservoirs, so the board said, very well, we will wait three months and see what the result will be.

162. You have additional land there, have you not?—We have.

163. Can you give us any information as to the quantity of land that you have upon each side?—Not at the moment, but we can furnish it, we have some acres to spare at any rate.

*Mr. L. Smith* applied for permission to further examine the witness at a future date.

Examined by Mr. Morice.

164. Can you tell us whether the sewage is discharged into the river before high water at any time or before the time you mentioned?—If the reservoir has been filled upon certain days that I have mentioned it would be.

165. I take it that in the instances where it has been filled by anything like an overflow, it is some time before high water?—I cannot tell at what time.

166. Is there any record kept of the time at which it would discharge when that was earlier than the ordinary time?—Yes.

167. And that can be supplied?—Yes.

168. Do you know whether it has taken place lately, very often?—I have stated that upon the south side it occurred on 43 days in the year 1881.

169. Can you tell us now what amount of solid matter, or anything connected with it, you consider to be the usual proportion in the sewage?—No, the chemist will tell you that.

Examined by the COMMISSION.

170. (*Chairman.*) If I understand rightly now your intention is that all the sewage of the area you are to drain should find its way into your reservoir, and be let out into the river at the beginning of the ebb, and for four hours afterwards?—Yes.

171. And if there were no storm water, but for the exception to which I will next call your attention, you calculate that your apparatus is sufficient?—Yes.

172. The exception is, that even now there is sometimes in dry weather, at a particular hour of the day, more than your reservoirs will hold until the time has arrived for emptying them?—I have said the quantity of the sewage has increased since we had our reservoir built, and that we have proposed to remedy.

173. You say there is another difficulty sometimes caused by there being a heavy rain and your reservoirs overflowing at unappointed times?—Yes, that is so.

174. They may overflow at any time from storms, and your sewage be carried up to London Bridge?—Yes, the storm water would, but at times of flood the sewage is very much diluted with the storm water.

175. Besides that, there are storm waters which find their way out in the way you describe from these different storm overflows, and that also falls in above London and below London?—It does the whole way down the river.

176. Besides that, there are still a few drains or sewers remaining which you have told the district people they must remedy?—That would be found to be very small indeed.

177. Then still further than that, there is such a thing, which you have indicated, as this, that you cannot say to people that they shall not discharge their storm overflow into natural outlets, such as, for example, the Wandle, between Carshalton and Croydon, and some people, as I understand you, have availed themselves of that opportunity to put sewage in?—They have.

178. You go to them and fight them under the Rivers Pollution Act, or something of that kind, I suppose?—No, under our own special Act, I think.

179. Or by the common law of the land that they have no right to commit a nuisance. Now are those all the ways in which sewage gets into the river?—Those are not the only ways, there is the sewage from Stratford immediately into the River Lea.

180. You do not drain Stratford?—No, it is outside the pink line; we have a pumping station upon the River Lea just outside our boundary (*pointing to the map.*) Then there is a little bit at North Woolwich, a few houses of which drain into the river, where the cost of carrying it to the outfall and pumping would be more than the houses are worth almost.

181. What is to be done there, are they to be allowed to continue?—There is another called Cold Harbour Sluice there, between the dock entrances, which cannot be connected with the sewers; then there are the Beckton Gas Works, which have an outfall; then there is the shipping of course upon the River Thames, their sewage goes in; and there is what comes in above our outfall.

182. Have you no means of resisting the Stratford sewage going into the Lea, and so into the river?—No, I believe we have no influence over that.

(*Mr. Michael.*) The Metropolitan Board of Works have no jurisdiction in that case.

183. (*Chairman.*) As I understand they have no jurisdiction as a Board, but would you not be able to get at them as a nuisance, although, perhaps, there might be a difficulty in proving that they were a nuisance?—I do not know how that would be.

184. At present you do not know that you have any jurisdiction or any power to prevent it?—We have not.

(*Mr. Michael.*) As far as the Metropolitan Board of Works are concerned, they have no jurisdiction; whatever jurisdiction there may be with regard to drains, that is vested in the district authorities under the Metropolis Management Act.

(*Chairman.*) I fancy there would be some common law remedy if it were a nuisance.

(*Mr. Michael.*) I am only addressing myself as to the jurisdiction of the Board of Works, not saying that there is not a remedy, but that the remedy is not in the hands of the Board of Works.

185. (*Chairman, to the Witness.*) Now I will ask you this question, and I assure you it is not with the view of propounding an opinion, because I have not one on the subject; but you say that the sewage is not like the solid float you put in the river, and that there is no reason to suppose that the sewage would go up in the same way that the float did, now is that so. You or whoever superintended the float took care that it was kept in mid stream?—Yes.

186. But may it not be that sewage comes out into the Thames at the time of low ebb or still water, and then it subsides and goes to the bottom, and then upon the return tide the water runs there and takes it further up; do you understand the point of my question?—Yes, I think we shall show clearly in the course of this inquiry exactly the line that the sewage discharge does take, and that at a very short distance below the outfalls it ceases to be objectionable. However that is a point of the inquiry which I would rather leave to other hands who can deal with it much more ably than I can.

187. You would say that however right you might be in saying yes, to the general question, yet that it is not so here?—That is so.

188. Now if I understand you rightly you might make another river half as big as the Thames to carry your storm water and sewage, alongside of it, but of course that would not be practicable, and the only way to entirely obviate the sewage getting into the river would be to let the storm water find its way into the river as of old, and have separate drains for the dry sewage matter; that could be done, I suppose?—It would be possible to do it.

189. But it is not impracticable altogether, is it?—It seems to me to be quite impracticable, as I stated, it seems to involve the re-draining of every house in the metropolis, and that would involve, in my opinion, an expenditure of 8,000,000*l.* to begin with, and such an interference with private rights and property, that I believe the nuisance of that would be far greater than the nuisance of allowing diluted sewage to go into the Thames in time of storms.

190. People might resist it, although I think they are so much used to the interference of Boards by this time, that they would look upon that as a necessary evil; but still, it would not be impractible beyond the expenditure of 8,000,000*l.* upon the houses and drains, and shutting off your storm water?—There are other difficulties connected with it. If you are going to have (which that would involve) a number of smaller branch sewers without rain water in them, it would render it necessary that you should have a greater fall in the sewers to keep up the flow, you would require more pumping stations.

191. You would not have current enough in the sewers?—No, you would have to establish pumping stations in different parts of London; it is so compli-

*Sir J. W. Bazalgette, C.B.*

27 July 1882.

cated and difficult a matter in my opinion that it would be impracticable.

192. Could you not flush them from time to time with the storm water?—No; I think if you flush them after you have once separated them you must do it by other means.

193. You could have an apparatus for the purpose of shutting off the storm water from the sewers when there was danger of there being an overflow, but that would involve a great many people having to pay attention to it, would it not?—If you close your storm overflows you would have to close your gulleys in the streets, and let the water flow down over the streets; and then by the time you got down to the low ground you would have a river flowing through the Strand and other places which would carry you away. We deal with storm water as a monster enemy which has to be got rid of as quickly as possible.

194. When you got it to your pumping station you said, I think, that 2,500,000*l.* would enable you to take it how far further down?—I said that from 2,500,000*l.* to 3,000,000*l.* would enable us to take the sewage, not the storm water, down the river 15 miles. I stated that there was no point within 15 miles that you could go to upon the river; if you go lower at all you must go 15 miles further.

195. (*Sir J. Coode.*) And then you are how many miles from the sea, in round numbers, about 15?—Yes, you would be 16 miles from Sheerness.

196. (*Chairman.*) That would undoubtedly free the metropolis from all your Crossness and Barking sewage, would it not?—Excepting in times of storm.

197. Then there would be the overflow water running, as you have described, but water coming from your outfalls would never find its way back to London?—No doubt.

198. It would find its way back to Gravesend, perhaps, some of it?—I think not, but a float would.

199. (*Sir J. Coode.*) There are 66 square miles upon the south of the Thames. Could you tell us how many miles will be below high water spring tides?—I could not tell you that.

200. Nor the number of inhabitants drained directly situated upon that area, would you be able to furnish that?—Yes.

201. And also upon the north side?—I could furnish that.

202. (*Chairman.*) I have one further question which I wish to ask you. You say that such people as the Acton people have no right to drain into your drains; would they not be content to pay you for the privilege, as indeed they ought to pay you, but at present they have not been rated to the making of the great sewer?—They are quite willing to make a contribution, but our answer is that our system has been designed for a given area, and that we cannot take them in. Our pumping stations are not big enough, and our reservoirs are not big enough, and altogether we could not take them in, in fact there is no limit. If you once begin to take outside districts in you may get up to the rim of the basin.

203. Taking in Harrow, for example?—Yes, Harrow, Hampstead, and Highgate, and upon the south side going much further back.

204. Upon the south side, if you went upon the chalk, you might go nearly as far as Reigate?—Yes.

205. (*Sir J. Coode.* Who can give us any more exact information as to the number of these small sewers draining into the Thames, you say you yourself are not in possession of the facts, could you indicate any authority or any official who could supply us with that information?—I think I could give you information as to what the number was five years ago.

206. And the number of inhabitants?— Yes, I think so; but what has been done since I should not be able to tell you, it would require a fresh survey of the river.

207. And those additional engines you spoke of at the pumping stations you regard as auxiliaries to be employed only in case of storm?—Yes.

208. (*Dr. Williamson.*) Is there in the construction of the sewers any arrangement for separating the solids which may be in the liquid, whether lighter or heavier than the latter?—There is every precaution taken to prevent solid matter getting into the sewers, first by careful scavenging, taking as much off the surface of the road as possible, and then by the gulleys by the side of the roads intercepting it again. If any quantity of solid matter does get into the sewers we have to take it out of the sewers, and that has to be done at very great cost, so that our great object is, naturally, to avoid letting solid matter get into the sewers.

209. But does not sewage normally contain some solids, do not the materials that have to be carried away contain solids in part?—Yes.

210. Does that go through the pump just like the liquid?—Yes, just the same.

211. The shingle and sand are the things that you try to keep out?—Yes.

212. (*Mr. Abernethy.*) I suppose many of the private drains that belong to the district authorities have very little fall to them?—There are some places where they have very little fall. If, for instance, you take the low districts between Deptford, Nine Elms, and Bermondsey, all that is a low district where there is a very little fall; but in the districts wherever there is a good slope to the land itself there is a good fall to the sewers.

213. In those cases of slight fall accumulation is likely to take place in the sewers in dry weather, is it not?—We do not find that accumulation takes place to any large extent now. I gave in a return of what actually gets into the sewer in the inquiry before Sir Charles Hartley.

214. In heavy storms everything is swept out of those sewers into the main drains and overflows, and would go into the river?—The first effect of a heavy storm is to wash away any deposit in the sewer, and then the water runs off completely clear.

215. It does not always follow that when a heavy rainfall takes place within the area indicated by the pink line, the Thames is in heavy flood?—That is to say you may have a thunderstorm that is local to the metropolis; you do sometimes, but as a rule in wet flow weather the Thames is in a state of flood.

216. (*Dr. Stevenson.*) With regard to the float, did you make any experiments with floats of different specific gravities to ascertain the velocity of the flow?—We did not upon that occasion, but experiments have since been made of the velocity at different depths.

217. And with different materials?—Yes, by sinking the body to a certain depth to ascertain what the difference in the surface mean velocity was. I should state that the floats, although having a head upon the surface were weighted to a considerable depth, so that they were affected by the whole depth of the tidal flow.

(*Mr. Michael.*) We shall give you full information upon that subject. We have divided it into sections as to width and depth.

218. (*Chairman.*) I suppose a good deal of that which is solid in its origin by the time it is washed out of your reservoir must get mixed up with the water as it were?—Yes, it does.

219. Do you have sometimes solid things such as bits of bone, and bits of iron, and things of that sort, which cannot be treated in that way, coming down the sewers occasionally?—We have very little of that kind of thing.

220. What happens to them when they do come down, do they find their way to Barking or Crossness?—As a matter of fact I do not think they do.

221. You do not know what becomes of them?—I do not know.

222. There are continual warnings put up that housemaids are not to throw anything but water down the sinks, and so on, which, I suppose, means that they do?—I presume, when that is done, they stick in the syphon trap, and the occupiers have to look out for that themselves.

(Further examination postponed.)

*Sir J. W. Bazalgette, C.B.*

27 July 1882.

(*Chairman, to Mr. Webster.*) Your point will be that the river is polluted?

(*Mr. Webster.*) I say, on behalf of the city, that there is below the outfalls, and to a certain extent above them, a very great pollution indeed, both by the deposit of the foulest matter, and also by the water itself being impregnated with sewage, and being at times exceedingly offensive. We also say (which is an incidental matter) that the water into which the sewage is poured is by the consequence of the system, (I do not say it is any fault of the Metropolitan Board of Works for the present purpose, but it is in consequence of the system adopted) already considerably polluted, and that, therefore, you have not sewage going into a comparatively pure water which would help to dilute it, but you have sewage going into water already contaminated to a large extent by the sewage from the metropolis, and that is one reason why the sewage is more a nuisance than it would have been if it went into comparatively fresh water or pure water. I say the pollution above Teddington or above Hammersmith is, comparatively speaking, immaterial. Your Lordship knows that a great part of the water that is supplied for the drinking of the metropolis is taken in at points very little above London; therefore, I do not think it will be contended that the sewage that goes in above Teddington is of much importance, but the sewage which is poured in from the metropolis before it gets down to the outfalls has a material bearing upon the question.

(*Chairman.*) It is some distance from Teddington to Hammersmith, you know. I do not know whether there are any sewage inlets there.

(*Mr. Webster.*) There are some, but substantially there is nothing of importance.

(*Chairman.*) What you say is that the river is a little, but unsubstantially, polluted before it comes into the area of the Metropolitan Board, but that pollution is so much more within that area as to make the river unfit to receive any further discharge, and that when the discharge is made at Barking into the river it goes into already very foul water.

(*Mr. Webster.*) Quite so, and then there will be something to be said as to the way in which the solid part of the sewage moves up and down in the water from Barking and Crossness.

Mr. Charles Beadle is called in and examined as follows:—

*Mr. C. Beadle.*

223. (*Mr. Morice.*) I believe you are a member of the firm of Beadle Brothers of Erith?—I am.

224. And you are also a commissioner, I believe, for the purpose of maintaining the wall of the river?—Yes.

225. How long have you known the river?—About 35 years.

226. Have you in the course of a large portion of that time had to go up and down the river a great deal?—I have.

227. Will you tell us when first you remember the river what was the state of the water?—It was clear and wholesome; fish could live in it.

228. How long ago was that?—It was 20 years ago.

229. Up to what time did it remain clear and wholesome?—Within the last 15 or 16 years.

230. (*Chairman.*) From where to where?—My knowledge of the river is more especially at Erith, and between Gravesend and London.

231. (*Mr. Morice.*) Do you know whether fish were caught in the river at Erith?—I have caught them myself.

232. How many years ago was that?—15 years ago, or 10 years ago I might say.

233. Do you remember whether there was any bathing in the river at that place?—Yes.

234. Was that at the same time?—It was later than that.

235. Do you remember when the outfalls were made?—I do.

236. What has been the state of the river since?—It has been growing gradually more dirty and more objectionable.

237. Have you ever caught fish in the Thames since?—Not lately.

238. Up to what time, as far as you remember, were fish caught it it?—I should say within 10 years.

239. In your knowledge was that part of the river at Erith particularly a good place for fish?—A very good place for fish when I first knew it.

240. (*Chairman.*) These works have been in operation more than 10 years, have they not?—I think the river was not charged with sewage to any great extent at first, it is gradually getting worse every year.

(*Mr. Bidder.*) I think the works were opened in 1864.

(*Mr. Morice.*) I shall show your Lordships that the river has been getting worse and worse, driving the fish farther down.

(*Chairman.*) There is a large volume of discharge, I presume, as London has increased.

241. (*Mr. Morice, to the witness.*) Have you noticed when on the river that there has been any disagreeable smell?—In hot weather there is a very disagreeable smell.

242. Have you noticed that particularly within the last few years?—Yes, more particularly with the last few years.

243. Does it get worse, or not?—Certainly, it gets worse.

244. Have you been in the habit of coming up the river from the Nore?—I have.

245. (*Chairman.*) Do they not catch fish, whitebait, in that neighbourhood?—It is all driven down to Sea Reach. I do not think there is a bit of it to be caught this side of Sea Reach.

246. (*Sir J. Coode.*) Driven down from where?—From Blackwall. When I first remember it, whitebait was caught at Blackwall.

247. Is it ever caught there now?—Never.

248. You mean to say the fish has been getting driven farther and farther down the river?—Yes, every year.

249. Is that within your knowledge?—Yes, certainly.

250. You are not a catcher of whitebait yourself?—No, but I have spent a great deal of my time upon the river.

251. (*Mr. Morice.*) Do you remember whitebait being caught off Erith and sent up to London?—Yes, I do.

252. Within what time has that been done?—Within the last 12 or 14 years.

253. Then coming up the river from the Nore will you tell us what you notice with regard to the state of the water?—It begins to get thick in the Lower Hope, the next reach to Sea Reach; it gradually gets worse until you reach the outfalls, which is, I should think, the worst place; then it begins to get better again until you get up to Greenwich, and before you come to London Bridge you come to very decent water again.

254. Then where do you say the worst part of the river will be as far as colour and smell are concerned?—From Blackwall to Greenhithe, I should say.

255. Have you noticed the river at the time when the sewage has been discharged into it?—Yes.

256. What is the state of the water there?—It is black, much like a sewer would be.

257. What is the time of the tide when the smell in hot weather is the worst?—From about half ebb to half flood, I should say, covering low water.

258. Do you notice anything beyond the smell of the water, do you notice any gas rising?—In hot weather it gives off a gas; the water turns black and

*Mr. C. Beadle.* 27 July 1882.

it gives off a gas from bubbles which have a disagreeable smell.

259. (*Sir J. Coode.*) Do you mean that you can see bubbles of gas rising?—Yes, you can, near the shore; you can see them break upon the surface of the water.

260. (*Mr. Morice.*) I believe you employ a good many men at Erith?—I do.

261. Have they to work at low water when there is a great deal of mud about?—They have.

262. Have you had complaints from them as to illness resulting from the smell?—I have had constant complaints.

263. They work in quite low water?—The vessels are allowed to ground, and the water leaves them, and the men have to work on the vessels with the mud under them.

264. What is the kind of mud depcsit there now?—It is black, disagreeable mud, quite unlike what it used to be.

265. Do you remember the bed of the river; that is to say, so far as the water would leave it before the sewage was discharged?—I do.

266. What kind of mud was it then?—Dark clay; it was not at all disagreeable, and worms would live in it then.

267. Are there any worms in the mud now?—I have not seen one for years.

268. I believe you had a steamer belonging to your firm sunk in the river a short time since?—We had.

269. She was raised, I believe, by the Thames Conservancy?—Yes, she was.

270. Did you find that there was a great deal of mud deposited in her?—Yes, a great deal.

271. What was that mud like?—It was very disagreeable; we had great trouble to get men to clear it.

272. Was there any smell with it?—A great smell.

273. I believe you have been upon the river a good deal during the last 25 years?—I have.

274. Have you noticed the drift of the tide, that is to say, how much a barge or a lighter would drift up and down with the tide?—Yes.

275. That is to say the extent to which she would go down upon an ebb tide?—Yes, I have.

276. Will you tell the Commission how far an empty dummy barge would go upon the ebb tide?—Do you mean from a given point to a given point?

277. Yes; take it from above the outlet; how far would it go down upon a spring tide?—It would go from Crossness outfall to Gravesend Reach. It would vary a little from tide to tide, because of course tides run at different paces, but that would be about the average.

278. Then it would meet the flood tide?—It would meet the flood tide.

279. Could you tell us how far it would go back then?—It would go back beyond the point it started from, all the time the tides were making.

280. At Erith there is a considerable bay, is there not?—A very deep bay.

281. And do you know whether the sewage matter at all collects in that bay and deposits?—It has grown up in the last 20 years 10 to 12 feet.

282. (*Sir J. Coode.*) In vertical height?—Yes.

283. When you say from 10 to 12 feet do you speak from actual measurement or merely from estimation?—I know of one buoy that was put in from 8 to 10 feet of water, and boats would float at it, at low water, drawing 8 or 9 feet, and that buoy is now out of water at low water.

284. (*Dr. Williamson.*) What is it there, sand?—No, mud.

285. (*Mr. Morice.*) The river makes eddies there does it not?—Yes, it does.

286. There is not the full strength of the tide right through the bay?—When the tide is running down a certain amount of water gets round the point, it eddies round, and a boat's head would turn up the river instead of down after rounding that point.

287. That is to say there is a kind of back water inside the bay?—Yes.

288. As I understand the sewage collects there and deposits upon the banks?—Yes, it does.

289. Does it remain upon the banks during the hot weather?—Yes.

290. Have you noticed any effects of the sun upon the bank?—It causes the matter to decompose and to give off a gas; that is what we suffer from most.

291. Do you know the causeway?—Yes.

292. Has there been any alteration with regard to that in the last few years?—That has been lengthened twice, if not more, and raised several feet within the last 20 years.

293. (*Sir J. Coode.*) How much has it been lengthened?—I should say 100 feet.

294. Do you mean upon each occasion?—No, altogether. I believe now they are obliged to have a floating one there, which lifts up and down with the tide, because it has been under the mud so many times, and it cannot be used without being moveable.

The witness withdrew.

Adjourned to Tuesday next at half-past 1.

---

## SECOND DAY.

### Tuesday, 1st August 1882.

PRESENT:

SIR JOHN COODE IN THE CHAIR.

PROF. ALEXANDER WM. WILLIAMSON, Ph.D., F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
WM. POLE, ESQ., F.R.S., *Secretary.*

Mr. CHARLES BEADLE called again. Further examined by Mr. MORICE.

*Mr. C. Beadle.* 1 Aug. 1882.

295. You were telling the Commission on the last occasion that the causeway at Erith had had to be lengthened recently?—It had.

296. Can you tell us whether there is any alteration in the tide line at low water from what it used to be, say, from 10 to 15 years ago?—Yes, there is a considerable alteration.

297. How much would you consider it had altered?—I should think it had altered 150 feet further into the river.

298. That would be at low water mark?—Yes.

299. Was there any alteration, as far as you remember, before the period you are speaking about?—No, it remained about the same.

300. And from about what year do you date the difference that you have noticed?—It has been growing up for the last 15 or 16 years, more particularly the last 10 years.

Examined by Mr. Webster.

301. You spoke upon the last occasion when we were here about a smell, would you just tell us whether you were able at any time to detect the smell of anything which, in popular language, you could describe. What does it smell of; I do not mean chemically, but popularly?—It resembles the smell of a badly ventilated water-closet, if you go into it in the morning.

302. A sewage smell?—I should say decidedly so.

303. You spoke of the men complaining of the smell during their work, have you yourself experienced the smell at the time they have complained of it?—I have.

304. I mean so as to be able to state that it is not the mere imagination of the men?—Oh, dear no.

305. Have you noticed at any time whether the smell that they have complained of produced any feeling when you smelt it, any unpleasant sensation beyond the mere smell?—In hot weather I cannot stand it.

306. In what way cannot you stand it?—It produces a headache and makes me feel sick, so that I am obliged to go away.

307. There are only one or two other matters I wish to ask you about; you have spoken of the causeways having to be lengthened, and the increase of deposit and the extension outwards of low water mark. What has been the character of the deposit around the causeways and over the causeways and out towards low water mark?—A slimy black mud.

308. And of the same character throughout, as far as the extensions are concerned?—Yes.

Cross-examined by Mr. Michael.

309. As you have lived at Erith 35 years, I suppose you have made yourself acquainted, from time to time, with the state of the river?—Yes.

310. And you know what has taken place there?—I do.

311. I understand you to say that for a period of about 15 or 16 years, there has been an accumulation of mud upon the western side of Erith Reach, somewhere near Belvedere?—Upon the south side I ought to call it.

312. I will call it the south-west?—Yes, that is so.

313. Are you aware that at the very period you speak of, that is the commencement of the 16 years ago, operations were commenced for the purpose of dredging away a bank which existed and ran out almost into the centre of the reach in the shape of a point opposite Cold Harbour Point?—Yes, it is called Erith Rand.

314. Besides that is it not the fact that at the very same period dredging took place upon the piece which is called upon the chart Rands Hill?—Yes, it did.

315. Could you give the Commissioners the exact time when the dredging began on Erith Rand?—I could not.

316. I am informed that it is about 15 or 16 years ago?—I should take that to be about the time it was completed.

317. Upon the map which is before the Commissioners you see a point running out opposite Cold Harbour Point, and to the east you will see a shoal called Rands Hill, with 14 feet of water; before that period, am I right in saying that the set of the tide was to sweep round that bight to the south and thoroughly keep it clean?—I do not think the tide swept round there more then than it does now.

318. Upon what datum do you found that opinion?—Because the tide in the river goes from point to point; it goes to what they call Cold Harbour Point from the point they call Jennngtree Point.

319. Since these two shoals have been removed from the point, has not the tide swept round and hugged the southernmost shore?—It never has done so.

320. Antecedently to the removal of those shoals, did not the tide sweep round the southernmost part, that is the bight that is called the Erith Bight?—No, it never did.

321. Was there no deposit there?—No, there was no deposit like there is now.

322. Was there slack water there?—There was slack water there always.

323. Has there been no difference in the set of the tide since those two shoals, Rands Hill and Cold Harbour, have been removed?—No; the bank called the Rand, which is now removed, was below Erith, and therefore did not affect the tide above Erith in running out. (*The witness explains the facts upon the plan.*)

324. Since that time is it not the fact that the tide has been deflected more to the northernmost part of Erith Reach?—No, not in my time it has not.

325. Can you at all precise the time at which in this portion of the reach the deposit commenced; take any part you like to tell me; in what portion, and when?—The deposit has been more especially in the last 10 years, and it is going on faster now than ever it did before.

326. Is it exposed at any part of the tide?—It is exposed at low water, 150 feet farther out than used to be the case.

327. And what about the northernmost portion?—In the northernmost portion there is no difference.

328. Not in the bank or in the depth of water?—No.

329. So that while the deposit has increased upon the southern side, the northern portion has been unchanged?—Only in the Bights.

330. Upon the southern portion the deposit has taken place to the greatest extent?—Yes.

331. And you say it has extended also to the west and north; not upon the northernmost side, to the north of the portion that you are speaking of, but still upon the southern side of the river?—Not so much towards Purfleet as it is in the upper part of the bight.

332. Have you taken any samples of the mud that has been deposited?—I did bring up some with me to-day. I do not know whether they will be any guide or not.

333. Have they been examined chemically?—No, I took them this morning with some men.

334. In what do those deposits differ from ordinary Thames mud?—They are much dirtier, much more offensive, and when the sun is out, which is when we feel it most, they are much more offensive than any other mud I know.

335. Do you know any Thames mud which, when exposed to the action of the sun at mid-day, is not extremely offensive?—It never was so bad as it is now.

336. What was not?—The Thames mud.

337. But you said that there was not any mud there 15 or 16 years ago?—No, I do not say there was none.

338. Has it increased so much as to seriously interfere with your comfort?—It has.

339. Where do you reside?—My works are upon the river.

340. Where do you reside?—I live three miles from the river; three miles south of the outfall.

341. Am I right in saying that your residence is in a line almost directly south from that portion of the river upon which there are a great many manufactories?—Yes.

342. Are your observations taken of this very disagreeable smell upon the river itself, or at your own house three miles away?—Upon the river itself.

343. At all states of the tide?—At low water when the mud is exposed and the sun upon it, then it is we find the most inconvenience.

344. Then it is not the water but the mud that you

*Mr. C. Beadle.*

1 Aug. 1882.

complain of?—The water also gives off a disagreeable smell.

345. Then are you able to determine which is the worst?—At high tide it is not so bad.

346. When is it worst?—At from half ebb to half flood.

347. During that time it is exposed to the sun?—It is exposed to the sun.

348. At your house do you experience any bad smells?—We do sometimes.

349. What is the direction of the wind when you experience bad smells?—From the north.

350. It would then be blowing over from the direction of the following works upon the northern side; to begin with Messrs. A. J. Crossfield's manure works, do you know Messrs. Crossfield's works?—I know them all.

351. And the candle factory close to it, do you know that?—Yes.

352. Is any nuisance created by those works?—A very great nuisance.

353. Are you able by any delicate sense of smell to determine when the smell comes from the mud banks and when it comes from Messrs. Crossfield's manure works and the candle factory?—It is quite unmistakeable.

354. Do you think you could distinguish between the smell of the refuse of gas works and the sewage smell that you can detect upon the river?—There is no difficulty when you are on the river in distinguishing between the smells.

355. But when you are at your works on the river you are flanked on the one side by Messrs Crossfield's works and the candle factory, and exactly opposite between the Erith Marsh and the magazine, there is Johnsons fish manure works; do you know Johnson's fish manure works?—Yes.

356. Is that a very sweet smelling place?—No, it is very disagreeable.

357. Do you know Bevington's manure works, is that very delightful?—No, they are all very disagreeable.

358. Do you know Collinson's glue and manure factory?—Yes, that is very disagreeable too.

359. Then besides that there is the Belvedere Guano Works; is that a very delightful thing?—I do not think that is so bad as the others.

360. I understand you to say that "of the bad," the smell of Johnson's glue and manure works is about the "baddest"?—That is about the worst.

361. So that, when the north wind blows, you have the disadvantage of having the whole of the smell of these six works blowing down over your residence?—Yes; but that does not apply to the works because they are very much above the manufactories.

362. In spite of your acute discrimination of smells, are you positively able to say that it is not the odours from those six works which come up to your premises and make you sick, but the smell of the sewage in the river?—I think so.

363. I should like to know how you are able to discriminate. Now what is the name of your house?—It is called Beadon Well. (*The site was pointed out.*)

364. (*Chairman.*) Where you placed the pointer was west of Erith?—But we are talking of the outfall, my house is three miles south of the outfall.

365. (*Mr. Michael.*) Do you smell any disagreeable smell from the river or the mud at your house?—I never detected it at my house.

366. Only the disagreeable smell of the factories?—That is all. Only the disagreeable smell of the factories.

367. How many workmen do you employ at your works?—From 200 to 300.

368. Would you be able to mark upon the Ordnance survey where your house is (*handing a map to the witness*?)—(*The witness did so.*)

369. Are those men of yours constantly employed, or do they fluctuate?—We keep them constantly employed.

370. Are the same men constantly employed, is it a shifting labour or do you have the same skilled labour?—It is not any of it skilled labour, but we have usually the same men at work.

371. What sort of health do they enjoy?—Not very good; we have had more laid up in the last three years than ever before.

372. Are you aware that Erith itself enjoys the happiness of being one of the healthiest places in the kingdom?—I believe that the death rate is low.

373. And not only that, but do you not know that their death rate from diseases likely to arise from sewage poisoning, or what we call zymotic diseases (I daresay you have looked at the reports of your medical officer of health), is extremely low?—I believe it is.

374. So that in the first place you have an extremely low mortality; and when you come to dissect that mortality you find that the mortality from zymotic diseases is very much lower than from other diseases?—It is so.

375. (*Dr. de Chaumont.*) What is the nature of your works?—We employ screw steamers and unload the goods into trucks and send them into the interior, and the workmen are employed working on and over the mud.

376. (*Mr. Michael.*) Could you tell me how many days of the year your men have been away from alleged illness?—I cannot.

377. Do you keep any record?—No.

(*Chairman, to Mr. Michael.*) Did you elicit the date at which the dredgings were completed.

(*Mr. Michael.*) We are unable to find the date at the present time, but the dredgings were completed about the period when this gentleman says the deposit commenced 16 years ago; and of course what we venture to say is that the one thing was entirely consequent upon the other.

Re-examined by Mr. Morice.

378. With regard to that last point, up to what time recently has the deposit of the sewage been worse than it used to be; could you fix any time for it?—I think it is getting worse every year, considerably worse.

379. You said it had been worse the last 10 years?—I think each year now would double itself in the evil, that is to say, we get twice as much deposit this year as we did last, as far as I can find.

380. I understand you to say that the deposit of low water mud which you have seen is more above Erith than below?—It is.

381. Is the part which my learned friend has asked you about just above Erith, a part where there is quite a bay and still water?—It is.

382. (*Chairman.*) What particular part of the Reach does that answer apply to?—The top part of the Reach from Jenningtree Point down to the causeway, or a little beyond, (*explaining the same on the plan.*)

383. Has the set of the tide been altered in the eastern part of the Erith Reach?—I think not in the least.

384. But opposite Erith, I think I understand you to say at the causeway it has?—At the causeway the mud has been silting up during the last 15 or 20 years very badly.

385. (*Mr. Morice.*) Do I understand you to say that the worst part is from Jenningtree Point to Erith?—Yes.

386. Do you know a place called Church Hole?—I do.

387. Is it bad there?—It is silting up very fast indeed there.

388. And that is some little distance above the village of Erith?—It is half way between Jenningtree Point and Erith.

389. Is the sweep of the tide in the lower part of Erith Reach just above Erith on the south shore or on the north shore?—Upon the north shore.

390. So that the portion near the south shore at Erith and just above is more like slack water?—It is.

391. (*Chairman.*) Was that so before the tongue at Coldharbour Point was removed?—It always had been.

392. You think the removal of the tongue at Coldharbour Point has not influenced the set of the tide above it?—It has not influenced the set of the tide at all above it.

393. Do you think you have been sufficiently experienced in the navigation of the river to give us an opinion upon that point?—I have been upon the river all my life.

394. (*Mr. Morice.*) Do you know where the yachts lie in Erith Bay?—Yes, there are two stations, one at the Corinthian and the other off the pier.

395. Where is the Corinthian station?—Near Church Hole.

396. (*Chairman.*) Is that opposite Belvidere church?—No, it is opposite Erith church.

397. (*Mr. Morice.*) Do you know whether there is any tide running there much where the yachts lie?—There is not so much tide there; that is in the slack water.

398. Do you know, from being upon the river, what course vessels take going up and down the river at this point?—They keep well out in the stream there; they go from one point to the other; they keep as near to the point as they can for water.

399. I understand you to say that as far as you remember, the tide has always hugged the south shore coming round there?—No, it is slack water upon the south shore.

400. And therefore in coming round, whatever it may do below Erith, it does not sweep the bay?—It does not sweep the bay from Jenningtree Point to Erith.

401. When do you notice the sewage mud gives off the worst smell?—In hot weather the sewage mud gives off the worst smell; it seems to rise up into the water and turns the water all black, and gives off a gas of some sort.

402. At what time of the tide would that be?—At low water, and from low water to half flood.

403. Have you noticed whether in hot weather there is any sewage deposited upon the bank?—I have not noticed anything that I could call sewage; it seems to be washed up into a thick state and diluted very much with water.

404. With regard to the situation of your house, which you have been asked about; your private house is at a place, I believe, called Belvidere, a little above Erith?—It is at the back above Erith, called Beadon Well.

405. Would that be affected by the factories that you have been asked about?—It would be about the same distance from them as the works.

406. In what direction would your residence lie as regards the factories compared to your business works?—My house would lie about south from the factories.

407. Therefore, if the wind were blowing from the north you would be more likely to get the smell of the factories at your house than at your business place?—Yes.

408. Have you any doubt when you are at your business place as to the sewage smell you have told us about?—I have not any myself.

409. And I understand your place is right upon the river?—Yes.

410. At low water have your men to work practically over the mud?—Yes; we put the vessels up upon the mud and let the water leave them, and until the water comes up again the men are working over the mud.

411. I understand you to say your men have complained to you of being sick and feeling the effects of the sewage mud?—They have in hot weather, they can scarcely stand it.

412. How long have you been living at Beadon Well?—About eight years.

413. Where did you live before that?—I lived nearer the river, at Belvidere.

414. Did you feel any ill effects from living so close to the river?—We were not so very close to the river, that was about two miles off.

415. Did you notice any river sewage smell more than you do now?—No.

416. Then I understand you to say that it is at your works, which are upon the river, that you smell it so much?—It is.

417. With regard to those factories, you know them all, I believe, pretty well?—I do.

418. Is there any doubt in your mind as to there being no difficulty in distinguishing between the smells which come from them and the sewage smell?—None, whatever.

419. Have you ever bathed in the river at this point?—I have in years gone by.

420. Was it different then from what it is now?—Yes, very.

421. Have you bathed in it lately?—No, I have not.

422. Would you like to do so?—I certainly should not.

Further cross-examined by Mr. Michael.

423. Are you aware that people were bathing there yesterday?—Very possible.

Examined by the Commission.

424. (*Chairman.*) You told us that the tide did not sweep the southern side of the river from Jenningtree Point to Erith; do you intend that remark to apply to the whole of Erith?—It applies to all except that bit I have mentioned in the bight.

425. Have you had to keep the foreshore clear from the mud?—We have to keep a gang of men slushing it clear.

426. How long has the pier been erected?—Forty-five years.

427. Has it been the case all along that you have to keep a man there flushing?—No.

428. When did this accumulation first appear?—It appeared more particularly the last ten years; it is dreadfully bad just now.

429. You know the place intimately, I presume?—Yes.

430. Are you able to say that previously to that time there was no necessity for this flushing?—No, there was not. I have been in business 30 years at this point.

431. (*Dr. de Chaumont.*) Was it only the last year or two that you have been obliged to keep the place clear?—No, we always had a man in there to look after it, but these last two years it has been almost impossible to keep it clear.

432. (*Chairman.*) But you said that it was not necessary to do so a few years ago?—Not as we must do it now; we have to keep a gang of men sweeping it night and day.

433. (*Dr. de Chaumont.*) What was the nature of the operation that went on in previous years?—There has alway been a little mud in the river, but it was a different kind of mud, and very much less of it.

434. Does it differ in its consistence, in its thickness, from what it formerly was?—In the thickness of the deposit each tide, and it is a very different kind of mud; now it is a slimy, greasy kind of mud; it is a lighter colour when it first deposits, and after a short time it turns black and stains anything that touches it.

435. In the former kind of mud was there any smell?—Not at all; nothing more than any clay would have. I have brought up some samples of this mud if the Commission would wish to see it.

The witness withdrew.

Mr. Joseph Robert Busby called in, examined by Mr. Morice.

*Mr. J. R. Busby.*

1 Aug. 1882.

436. I believe you live at No. 59, Parrock Street Gravesend, and are a Trinity River pilot?—Yes.

437. How long have you known the River Thames?—I am now in my fortieth year on the river. I was not born upon the Thames, but I was brought up alongside of the Thames the whole of my life. I have been upon the water 40 years come April next.

438. You have been a pilot for about 21 years, I believe?—I have been a pilot for 21 years.

439. You remember the state of the river before the outfalls were opened?—Yes, I knew the river many years before that.

440. Will you tell us what was the state of the river between Woolwich and Gravesend before the outfalls were opened?—Thirty-nine years ago it was a most beautiful river, very clear and very clean, my tea was made of the water from the Thames both for breakfast and for tea, and for years I drank no other water; if you had gone in the steamboats which I was on, as a passenger, you would have had that water to drink.

441. At that time you say the river water was generally drunk on board the steamers?—Always, both by passengers and crew.

442. Up to what time did that continue?—Our vocation is so different at times that it is difficult to remember dates. I was in those steamers for 10 or 12 years; and then before I was a candidate for the Trinity House I had to go to sea for 12 months so that I cannot give the years exactly.

443. When did you notice any alteration in the state of the river?—In 1855; in 1856 it was worse; in 1857 it was very obnoxious; in 1858 it was dreadful, and in 1859 it was worse still. This was owing to the number of outlets, from Jenningtree Point to Blackwall. It was a very warm summer in 1859.

444. Since that time has there been any alteration at all?—In 1860 we had a very wet summer, and that made it somewhat better, because a wet season makes it different.

445. Have you noticed anything, taking from 1863 or 1864, in the part you mentioned between Woolwich and Gravesend?—Taking the river between Woolwich and Gravesend, in 1860 it was a very wet summer, and it was better, it is purer again this summer than it has been for a long time; in 1863 it was very fearful, and in 1864 the sewer opened.

446. Have you noticed any alteration of any kind in the state of the river from 1864?—Yes, these last four or five years, to leave Gravesend at 5 in the morning and to come up on board of a ship with a tug towing ahead of you to stir the water up is dreadful; from Erith to Woolwich is, I consider, the most obnoxious, and the largest cesspool in the world. I often hold my handkerchief to my nose for an hour together.

447. How long have you noticed it getting so bad as that?—I have come down with vessels even eight or nine years ago, and the mate has knocked the crew off work, as a rule now they generally pump with a hose on the deck, they do not clean it as they used to do, and the mate has very often knocked the men off from scrubbing the decks on account of the water being so filthy and black as ink. I have seen that myself, that the mate has knocked them off and let them begin again in Long Reach.

448. Where is Long Reach?—That is below Purfleet.

449. Is the water better there?—I think so; the obnoxious stuff, unless it is a very hot summer, has not come into Long Reach yet.

450. That was eight or nine years ago; from that time I understand you to say it has been getting to be as bad as it could be near Gravesend?—If this had been a very hot summer, and there had not been any rain, you would not have been able to bear yourself.

451. You know when the outfalls were opened?—I went by about half an hour after the Prince of Wales had opened the southern one.

452. That was in 1864?—It was in 1864.

453. Have you noticed the state of the banks about Woolwich Reach?—I have not noticed the state of the banks about Woolwich pier, but I have had a vessel lying at Erith, and when there has been no accommodation I have very often slept on shore, and I have then to come down to go on board in the morning before the tide, and the place has been very nearly ankle deep on the shore with the slush which has come out of the sewer.

454. That is at Erith?—Yes.

455. At what part of Erith have you noticed that?—At the causeway.

456. What is the causeway?—A kind of a stone bridgeway.

457. Have you noticed it at all above Erith?—Yes.

458. You know Church Hole, do you not?—Yes.

459. Have you noticed it there?—Yes, I have noticed it upon the shore; but the thing I have particularly noticed it for was not to get ankle deep in it. It must have been upon the shore to have been both below and above the causeway.

460. Do you know the way the tide sweeps round just above Erith?—Where the bights are; it goes into the bights, and it would naturally do so. It comes from Rainham over to the other bight; it sweeps from bight to bight.

461. Let me ask you with regard to the drifting; how far do you consider that sewage put in, say, at high water or a little after high water, at Crossness would get down?—It would, I dare say, extend as far as Gravesend with a spring tide, but with the water that is above and the water that it meets, it would not be so obnoxious as it is in Barking Reach, it is not likely.

462. That is to say, the further it gets down the more the water mixes with it?—Yes; and of course the upper water mixes with it.

463. Upon a spring tide it would get down to Gravesend?—Yes.

464. And upon a neap tide where would it get to?—I would say just below Greenhithe with a neap tide.

465. Then of course it would meet the flood coming back, would it not?—Yes.

466. Could you tell us how far it would be likely to get back on a flood?—I should fancy that it would go nearly up to Greenwich. My idea is that the stuff itself which had gone down the river as sewage had gone down to the bed of the river, but the sewage water itself would come up as far as Greenwich, I should think, or even further.

467. Is the sewage which goes down upon the ebb deposited?—The sediment is deposited in the bed of the river, but the dirty water comes back; and not only that but I have gone down with a tug after I have finished my vessel, and you would see just at high water a large round ball from the outlet right over to the other side and extending a mile, black as ink.

468. (*Chairman.*) You mean a circle?—Yes.

469. (*Mr. Morice.*) What time would that be?—That would be as near high water as possible; for in the summer season we prefer a tug, to coming down by train.

470. In what month have you noticed it worst?—In the month of August and July. If you want to smell it you should leave Gravesend on the tail of the neap tide at 5 or 6 on a summer's morning; it should be a still morning after a fortnight's dry weather. If you then came up the Thames, you would see the largest cesspool in the would.

471. (*Chairman.*) That is leaving with the first of the flood?—About an hour of flood at neap tides. I have many a score of times held my handkerchief to my nose in Halfway Reach and Barking Reach, the smell was so strong.

472. (*Mr. Morice.*) Do you know that some years ago fish used to be caught at that part of the river?—Yes, lots of fish, flounders, whitebait, and shrimps.

473. Where was that?—In Erith and Halfway Reach too; flounders were caught at Erith 40 years ago.

474. How lately could you say that fish have been caught at Erith?—I could hardly say, because I used to go every week up and down the river; but now I have my ship to look after, and that is all I care about.

475. But you remember fish being caught in years gone by?—Yes, I do remember fish being caught 30 years ago at Erith.

Examined by Mr. Webster.

476. You said that before the sewer opened in the year 1864 the state of the river was very bad?—Up in the Pool.

477. What part of the river was bad before the sewer was opened?—From Blackwall up to the House of Commons.

478. Has the upper part of the Pool improved since the outfall was opened?—Very much so. I have slept on board a tug in 1859 in the upper part of the Pool, and I could hardly breathe.

479. But the lower part of the Pool is very bad now?—Yes; we get it now, and the members got it then.

Cross-examined by Mr. Michael.

480. What age are you?—Fifty-three.

481 And you have been 40 years upon the river?—Yes.

482. Do all men who have been upon the river for 40 years present the fine appearance that you do?—Not at all, I am a very steady man.

483. Did you always present the same appearance that you do now?—I do not know that I did; perhaps I have less to do now.

484. However dreadful the water was in the year 1858, which you have described to us, it made admirable tea?—This water which I told you was used for making the tea came from the Thames at half ebb at Blackwall or high water at London Bridge.

485. Did you think at the time that you were drinking diluted sewage?—I do not know. I drank it as a lad would; the water was poured into a cask and the sediment went down to the bottom of the cask and was washed out the next day.

486. You did not think about it?—Not at all; but it was a very splendid river 40 years ago.

487. Now you are thoroughly acquainted with the course of the river, and especially at Erith?—Yes.

488. Do you remember when the dredging took place at two points, one almost exactly opposite Little Cold Harbour, called Great Cold Harbour, and another called Rand's Hill?—Yes.

489. Do you remember the dredging?—Yes.

490. What was the influence when those points were dredged upon the course of the tide?—Upon Rand's Hill I have seen a vessel 6 feet fast; it was so shallow there.

491. At that time I think there was 14 feet of water there?—No; 40 years ago there was not 14 feet of water there; on each side of the hill you might have found it.

492. There is at the present time 14 feet of water?—There is plenty of water there now.

493. But it was 5 feet?—I have seen a Barking smack, which used to go from Barking then and draw about 5 feet of water, fast there.

494. Is it not the fact that before that point was dredged away the tide was obliged to go outside that point and was deflected on to the other side?—(*The witness explained upon the plan.*)

495. Can you tell the Commission, as nearly as possible, what was the time when that point was dredged away?—I do not think it possible that can make any difference to the set of the tide.

496. Never mind the consequence of your answer; I want to know if you can tell the Commission when that event took place?—Nearly the whole of my life have those dredges been at work from Rands Hill to Erith, and from Erith to Rands Hill, and they are now in Long Reach, and it is an extraordinary thing that they should think of making water in Long Reach; I suppose they get better ballast there than anywhere else; but I should think those dredges were between Erith and Rands Hill for 15 years.

497. During the last 15 years have vessels pursued a different course from what they pursued at a period antecedent to that time?—Since 10 years ago they take the middle of the Rand's and do not care about the hill at all.

498. They go over what you say used to have 5 feet of water upon it?—Yes.

499. What influence had the taking away of that point upon the set of the tide?—I do not think it can affect the set of the tide, because the tide must set into the bights, and from bight to bight.

500. But was not it the fact that before that was taken away the tide was deflected round the nose of that point?—It is so now.

501. Before it was taken away, I ask you?—It was not so shoal as all that, but I am referring to the piece of ground in Erith Reach.

502. What was the effect upon the tide of removing the shoal at Rand's Hill?—The tide would run rather faster upon the north side of Rands Hill than it did formerly.

503. Did the tide run harder in this portion that I call the bight, or did it run sharper upon what I would call the northern portion? what was the effect of removing those two points?—I do not know, I could not say. I do not say what effect the removing of a shoal can have unless it is a very bad shoal.

504. But according to your account ships were obliged to go round that shoal, and now ships can go over it?—Yes, that is so.

505. Therefore there was a very much larger quantity of water flowing upon the north side than used to be before?—Yes, no doubt.

506. Would the effect of that be to make more still water upon the southern side?—That I could not say. To us the tide is one thing, we know all the sets of the tide, if we are in a fog we know every inch of the ground, just as a policeman knows every lamp in the street; but as to the effect of the tide running harder in a particular direction since the shoals were taken away you are going beyond me, it is a thing I never thought of.

507. I believe there has been a greater deposit of mud in this portion of the river in the last 10 years than there was before?—There has been.

508. Upon which side?—Upon both sides, in at Erith and in at Rainham Bight.

509. Although there has been a greater flow down the river, that has been accompanied by a greater deposit of mud?—Since the sewers have been opened there is a larger deposit of mud in the lower part of the river than ever was known before, but it is a thing I never studied. Whether the tide has gone harder since they took the two shoals away or not I cannot tell, it took two* years to take them away.

510. But it is quite clear when two years' labour had been expended upon the shoal you were able to take your vessels in the new course?—We had to go up to the south or north of that Rands Hill, either to the north or south.

511. You were obliged to zig-zag the course of your vessel to avoid the shoals?—We were.

512. And now you go over them?—That is so, but

* Subsequently altered by the witness to "twelve" years."

*Mr. J. R. Busby.*

1 Aug. 1882.

whether it affects the set of the tide or not I never thought of.

513. I understand you to say that in the year 1858 the condition of the water was dreadful ?—That was so.

514. How far up did that extend ?—From Woolwich up the river opposite here.

515. That is to say from Woolwich up to the Houses of Parliament, in 1858 and 1859, the river was in a dreadful condition ?—Yes.

516. Having been diluted with a quantity of water in later years it is not so bad ?—No.

517. Now I suppose you are dependent like everyone else upon the amount of tide, as to the time at which you will go up ?—Yes. In the morning, leaving Gravesend at 5 o'clock, if you come up Halfway Reach at about half-past 7 or 8 o'clock, or half-past 6 or 7 and it is as still as a ditch, the stench is something fearful.

518. Is that because by the action of the vessels going up you disturb the bottom of the river ?—The tug ahead of you stirs up the surface of the river.

519. And you have seen this splendid black india rubber balloon preceding you ?—Yes ; only in respect of noticing whether the tide runs any harder since you have removed the shoals I cannot say.

520. (*Chairman.*) What depth of water was there over the Rands Hill 30 years ago ?—About 5 feet of water. I have seen a small vessel ground there.

Re-examined by Mr. Morice.

521. Now you go over it without taking any account of it ; you do not alter your course or consider the tide so far as you have seen ?—No, we do not alter our course at all.

522. As far as you have noticed, the taking away of the shoal has made no difference in the set of the tide ?—I do not think it has.

522*a*. (*Chairman.*) I think the witness said he had not noticed it and was not prepared to say.

523. (*Mr. Morice.*) I think you say, starting from Gravesend you notice the smell more than at any other time after 5 o'clock on a hot summer's morning ?—Yes, 5 o'clock in the month of July or August, or if it is very dry in September.

524. A hot steamy morning ?—Yes ; if everything is still and quiet it is something frightful on those mornings.

525. With regard to the deposit of mud you have told my learned friend that since the sewer has been opened you have noticed the deposit of mud being greater than before ?—Yes.

526. Have you noticed it at all coming down between Erith and the point above Erith ?—Erith, you may say, is the essence of the jelly bag ; they get the worst of it at Erith.

527. That is your opinion ?—Yes.

Examined by the Commission.

528. (*Chairman.*) Mr. Beadle has told us that along the southern shore of the Thames at Erith, the water is slack, do you agree with him ?—It is slacker than it is in the middle ; but still for all that it is slacker upon the north shore than it is upon the south shore.

529. But you said the water ran from bight to bight ?—It is slacker upon the ebb tide close in to Erith than it is upon the north side.

530. But is the water slack upon the southern shore of the Thames opposite Erith ?—Not on the flood, it is slacker than it is in the middle, it stands to reason that the point takes the rush of the tide off.

531. (*Dr. de Chaumont.*) Is the tide any slacker than it used to be ?—I do not think so. I should know if I were going, as I used to be, in the steamers ; but I think something ought to be done owing to the fearful state it is in.

The witness withdrew.

Mr. William Sandford called in, examined by Mr. Morice.

*Mr. W. Sandford.*

532. I believe you reside at Tudor Lodge, Gravesend ?—I do.

533. And you are a shipowner ?—Yes.

534. How long have you known the River Thames ?—For 45 years.

535. I believe you have been a pilot upon the river for a considerable time ?—Yes, for 28 years.

536. (*Chairman.*) Are you a Trinity pilot ? — I was a Trinity pilot.

537. (*Mr. Morice.*) Do you remember the outfalls at Crossness and Barking being opened ?—Yes, I do.

538. Do you remember when that was ?—It is about 15 years ago.

539. About 1864, was it not ?—On or about that time.

540. Could you tell the Commission what was the state of the river between Woolwich and Gravesend before the outfalls were opened ?—It was very bad ; very bad indeed.

541. Where was it bad ?—It did not extend so far as Gravesend, but from Jenningtree Point to Woolwich and Blackwall it was in a fearful state.

542. That was from Jenningtree Point up the river to Blackwall ?—Yes.

543. (*Mr. Bidder.*) Jenningtree is upon the south side off Halfway Reach ?—It forms Halfway Reach.

544. (*Mr. Morice.*) Then I understand that from that point to Blackwall the river was in a bad state ?—And further up, up to London Bridge, *i.e.*, before the outfalls were opened.

545. What was the state of the water down the river from Jenningtree Point to Gravesend ?—They did not feel it at all there before the outfalls were opened.

546. Since the outfalls have been opened have you noticed any difference in the state of the water in the lower portion, viz., from Crossness, where the outfalls are, down the river to Gravesend ?—For the first four or five years after the sewer was opened the water was fairly clear ; it was very good indeed for four or five or six years.

547. Where was it good ?—From Crossness right down to Gravesend ; but since then it has gradually got so bad, and now it is as bad as the upper part was before the sewage was let out at Crossness.

548. Is that in the last few years, or in how many years ?—It has been gradually getting worse the last eight or nine years, not so bad as it is now, but it has been gradually getting worse.

549. I understood you to say it was getting as bad now as the upper part was before the outfalls were opened ?—Yes, that is upon the low water, on the neap tide at low water.

550. That is the time when you consider it to be the worst ?—You feel it more then, the tugs turning their paddles, and the screws their propellers, and the stream being sluggish, stir it up like a black pool ; but coming further up when the stream is stronger you do not notice it so forcibly.

551. What time of the year do you notice it worst ?—Always in the latter part of August, September, and October.

552. And, I suppose, after a run of fine weather ?—Yes ; heavy rains, of course, help you over the outlet a great deal.

553. Have you noticed the mud upon the banks of the river about that part ?—Yes, it is accumulating fast under Crossness ; we used to anchor there in 14 feet and 14 feet 6 inches of water under what we call "Tripcock's" or Tripcock Point ; now you cannot approach it ; you will not find more than 8 or 9 feet at low water in places where you used to find from 4 feet to 14 feet 6 inches.

554. Now you say that from there down, there has been a great deposit of mud of recent years ?—Yes, in the last 8 or 9 or 10 years it gradually got worse ; we got worse water round Maggotness ; it has gradually got worse from the time of the opening of the outfall.

555. Do you know the part of the river from Jenningtree Point, that is the bottom of the Halfway Reach, to Erith ?—Yes.

556. Has there been a greater deposit of mud upon the south shore in recent years ?—Now there is ; there has been more difference there in the last five or six years.

557. (*Mr. Bidder.*) Whereabouts ?—Take it from the "stink factory," as we call it, in Jenningtree Reach. (*The witness pointed out the localities he was referring to upon the plan to the learned counsel.*)

558. (*Chairman.*) You are speaking of the part below Jenningtree Point ?—I am referring to the deposit of mud, not to the factories.

559. (*Mr. Michael.*) I merely mentioned them because the first witness said something that directly affected them, but there are hundreds of factories to be mentioned.

560. (*Witness.*) Why I said the factories was, that below Jenningtree Point, and before you get to the factories there is deep water ; there is one quarter of a mile from Jenningtree Point till you get to the shoal which we call the Sugar Loaf ; there is deep water opposite, the factories, and when you get lower down off Jenningtree Point you come upon an accumulation of mud.

561. (*Mr. Morice.*) From Jenningtree Point round the bend of the river to Erith has there been a deposit of mud greater in recent years than there was formerly ? —Yes, more particularly in the last five or six years ; it is marvellous how it has grown up there.

562. Can you tell us how the set of the tide is down Erith Reach, say from Jenningtree Point ; that is, Erith Reach down to Erith ?—It sets from Jenningtree Point (I am speaking of the ebb tide) below those factories, and then it comes into the curve of the land, and then it takes us straight over to Cold Harbour Point.

563. (*Chairman.*) That is Little Cold Harbour ?—Yes, Little Cold Harbour, where there used to be the old Gravesend boats' channel before the hill was taken away ; we used to go between Rand Hill and this part ; now the rush of the tide and these machines have taken it away.

564. (*Mr. Morice.*) You know there is Cold Harbour Point opposite Erith and Little Cold Harbour just about half way up the Reach ; now which do you mean to refer to ?—The one we call Cold Harbour Point is the one opposite the lower part of Erith. (*The places being pointed out by counsel to the witness upon the plan.*)

565. (*Mr. Morice.*) The witness is referring to Cold Harbour Point.

566. (*Witness.*) The small point we call "False" and there is deep water ; the tide sets over that way towards Erith, and then shoots itself over to the other side towards Cold Harbour.

567. You know what is called Church Hole ?—Yes.

568. From below Church Hole towards Erith, is there any strength of tide ?—There is very little on the ebb tide.

569. What is there upon the flood ?—Upon the first part of the flood you would get a strong tide there.

570. (*Chairman.*) Is it stronger than upon the north side ?—You get it stronger upon the first part of the flood ; but as the water flows, the water distributes itself, and at two-thirds flood there is very little tide indeed.

571. (*Mr. Morice.*) Therefore upon the ebb in coming down would a vessel come into the bight of Erith Bay or would she keep out well in the middle of the river ?—A vessel would not come into Erith Bay. I understand you are referring to a ship drifting.

572. Suppose she is being towed ?—You can tow her where you like.

573. Take a loaded vessel going down the river ?—Letting her alone, having no sail and no propelling power she would not go into Erith Bay.

574. (*Chairman.*) If you were taking her down, as a pilot, would you take her into Erith Bay ?—No, I should take her on to the north shore and then cross over into the bight for Erith ; not into the upper part of Erith, but then you would come into the Erith part in order that you should have the deep set of water over what used to be Rand Hill.

575. Over the deep water between Little Cold Harbour and Cold Harbour Point, and then across to the southern part of Erith ?—Yes.

576. (*Mr. Morice.*) I take it that in Erith Bay round by Church Hole, if you were taking a vessel down you would take her in the middle of the stream and make towards the northern part ?—Church Hole is a deep hole, it lies with the church upon the west by south ; we take the deep water and sweep round Cold Harbour proper, but we do not come so high up as Church Hole.

577. In that part of the bay that you would not go into, is not there slack water ?—Yes, truly ; that is why the mud curls up, it is the counter tide that causes that settlement to stir up ; we have one hour difference of tide from Gravesend to London ; now you can go to Yarmouth, that is, outside Yarmouth sands, where there is only one hour's difference between Yarmouth and the Nore, that is 110 miles where you have only one hour's difference, and you have an hour between Gravesend and London ; so that although your tide appears to be running out yet your under current is running up. I have proved that by throwing a basket overboard with ballast in it and sinking it, and the basket will propel the boat against the stream.

578. There is a counter current in Erith Bay ; is that what we are to understand ?—Yes, that is so.

579. Are we to understand that that is not upon the surface but a little above the bottom when you spoke of sinking a basket ?—The basket would be sunk within a foot of the bottom.

580. Does that current appear upon the surface ?—No.

581. How far below the surface would you have to sink the basket before you would meet the counter current ?—Within 4 or 5 feet of the bottom ; it does not come all at once, but you begin to perceive it when it is within 6 or 7 feet of the bottom, but more particularly within one foot.

582. That is during the last ebb ?—During the last quarter ebb.

583. And only during the last quarter ebb ?—Yes.

584. How fast would you say the current runs up against the tide ?—There is not much current, you might say a quarter of a knot.

585. At the last part of the ebb in Erith Bay which we have been talking of, is not there a young flood making up at the last part of the ebb ?—Yes, that is the very thing I have been talking about ; there is a lot of stuff deposited from the factory and that under-current curls it up.

586. What do you mean by the "factory" ?—I mean the outlet at Crossness.

587. (*Chairman.*) Are we to understand from you that this under current is the young flood creeping up ; is that your opinion ?—It is my opinion because I have proved it.

588. Then what you tell us is this, that this set upwards is the young flood creeping up under the last of of the ebb ?—Yes.

589. Does that go on increasing ?—Directly the flood is made then that ceases, but it ceases gradually.

590. (*Mr. Morice.*) You know the river well as you have just been telling us about the state of the tide. Now if sewerage matter were put in at high water upon the spring tide, how far would it get down upon the ebb below Crossness ?—I do not believe it would reach further than Purfleet, but taking it that it might reach a little further, at all events it would not go mech further, say, to Greenhithe ; for instance, you

*Mr. W. Sandford.*
1 Aug. 1882.

never pick up a body that is drowned about Crossness below Purfleet; should a man drown in Half-way Reach or anywhere there, the body may reach Purfleet, but I never remember it being found below Purfleet.

591. (*Mr. Michael.*) At spring tide?—At spring tide you might find it a little further out, but very little.

592. (*Mr. Morice.*) On the neaps how far would it get down?—A very little way, it might get to Erith perhaps.

593. Have you ever suffered any illness from the state of the water yourself?—I could not say that I have felt that, I may be glad to get a mouthful of air and that sort of thing.

594. You feel a sort of choking sensation?—Yes.

595. Do you remember when there was fish in the river?—Yes, I do, but I should like to say this, that we used to make our best effort to watch the time to get clear of the stench, we would lose an hour to clear the stench.

596. Now I was asking you do you remember fish in the Thames between Woolwich and Gravesend?—Forty-five years ago I brought a voyage of fish from Iceland in the well, alive; we lay four days at Gravesend, and we used to send eight or ten score up to market every day, then we moved from Gravesend to Greenwich.

597. (*Chairman.*) You kept them alive in the well?—Yes, the ship was so constructed that we could keep the fish alive in the well.

598. What is the longest time you have kept fish alive in the well?—Eight or nine weeks, we used to keep them alive during the voyage.

599. How long have you lain at Gravesend with the fish alive?—I have lain there a fortnight.

600. Did you keep the fish alive and in good health?—Yes, you might pick out two or three dead; we used to have a staff to pick them out, but still they would not be very numerous. Then we would go to Greenwich, and market the rest from Greenwich.

601. (*Mr. Morice.*) How many years ago, taking the most recent case, have you brought fish up the river to Greenwich?—It is 38 years ago since I had any fish.

602. Do you remember when fish was caught in the river itself?—Yes, for the best of good reasons, that my mother had several of these vessels.

603. How long ago is it since fish were caught in the river up at this part?—Up to about 12 or 14 years ago they were caught.

604. Whereabouts would that have been specially?—The whitebait was caught at Blackwall.

605. Up to what time can you tell us?—No, I feel a little adrift in dates; when you talk about the sewer having been open obout 15 years it makes me begin to think; but 25 years ago I have caught salmon and sturgeon too, below Woolwich.

606. (*Mr. Michael.*) How many?—It was a common thing to do to catch salmon and sturgeon there.

607. Every season?—Yes, every season; the sturgeon lasted longer. Even now it is common for them to catch sturgeon, but it is down towards Hole Haven and towards the Nore.

608. (*Mr. Morice.*) How far down now since the outfall has been opened are fish caught?—You cannot stop at Gravesend with live fish.

609. Not in a well?—No, you could not keep them alive, they would die.

610. Why?—Because of the pollution of the water; the water is so bad.

611. Do you know the state of the mud on the banks on the lower part between Woolwich and Gravesend?—I do not see that there is much difference in it; it may be darker, but I could not say much about that; I have not been ashore to prove it. I have to do with the water and with the navigable part of the river.

Cross-examined by Mr. Bidder.

612. As I understand the mud that produces the offensive smell has been accumulating in the parts you have indicated of late years?—Yes.

613. And that is what has made it so much worse?—Yes.

614. It used to be deep water there?—Yes.

615. Now you have instead of deep water and a clean bottom an accumulation of mud?—Yes, quite so.

616. That is what accounts for the change you have described?—Quite so.

617. The Thames mud, as we know, has always been a very offensive stuff?—Yes, it has, for the last 35 years.

618. Now, about the fish; you said you could not keep live fish now in a well at Gravesend; have you ever tried it?—No.

619. Did you ever know anybody who had tried it and failed?—I know that our fishing boats belonging to Gravesend, if they get fish, sweep them out before they come to Gravesend to save their lives.

620. Do not some of the boats come up to Billingsgate with fish in the well?—No.

621. None of them?—I do not think so. I am not sure whether some of the eel men do or do not; it is possible some of the eel men may, but I think not.

622. Now with regard to the salmon and trout, you have awakened my interest in a way that I hardly expected?—I spoke of salmon and sturgeon.

623. Where were they caught?—They were caught in Long Reach.

624. When was the last salmon caught in Long Reach as a matter of curiosity?—It is a good while ago since the last salmon was caught in Long Reach, but last summer there was one caught between the Nore and Gravesend.

625. In the nets?—Yes, but it was not an uncommon thing to catch salmon in Long Reach; I am speaking now of 20 years ago, and not at all an uncommon thing to catch sturgeon.

626. You said that sewage put in at high water at Barking or Crossness would not reach Purfleet?—I think not, at any rate not lower than Greenhithe.

627. Have you ever tried that experiment—you mean on one tide?—I mean on one tide.

628. You have not tried the experiment?—I have not.

629. It is a mere general opinion?—It is nothing more than my opinion.

630. Now how about the smell. There are a great number of villainous smells along both sides of the river, are there not?—There are smells from factories that are offensive when you get high up.

631. Have you ever tried the smell of the fish manure factory?—I have not noticed that. I have noticed the factories higher up, at Blackwall.

632. When was the last occasion when you noticed any smell from the river?—It is five or six weeks ago.

633. Where was that particularly?—That was from Erith, and from Jenningtree Point up to Crossness, and as bad as we get along. I did not see much difference.

634. You smelt it from Jenningtree to Crossness?—Yes. I went up in my own tug for pleasure, and I remarked "This is coming it rather stiff. I will not "go again."

635. Was that high water or low water?—Low water.

636. It was between those points you first noticed it?—Yes, that was the first time I noticed it; but afterwards I noticed it all the way.

637. I wish to know between what points you noticed the smell?—It began at Jenningtree Point and continued.

638. It was worse when you got to Crossness?—It was worse when I got to Crossness, but it was not nice all the way.

639. You may put it between those points?—I would not distinctly confine it to between those points

I could not say "it is sweet here and sour there," but it might be a little better at the beginning than it was at Crossness. It was at Jenningtree Point that I first smelt it. It was very bad when we got to Crossness, and it was not quite so bad afterwards, but I do not say it stopped; it does not stop all at once.

640. How far would you say it extended up perceptibly?—I do not know. I only know this, that it was very bad there, and I smelt it all the way up.

641. That is five or six weeks ago. Can you refer to any other occasion when from personal observation you have noticed the smell?—No.

642. That is the only occasion upon which you observed it?—No, certainly not. Always when I have navigated the Thames I have smelt it.

643. You did not quite hear the whole of my question. Can you refer me to any other occasion upon which you personally have observed an offensive smell?—Upon all occasions when I have navigated the river during the last quarter ebb.

644. Between the same points?—Yes.

Re-examined by Mr. Morice.

645. I understand you have not been going upon these occasions that you have been asked about, specially to smell or to ascertain the stink?—Certainly not.

646. Whenever you have been in the neighbourhood you have smelt the stink?—Yes.

647. And that extends more or less all the way up?—Just so.

The witness withdrew.*

* The witness subsequently added to his evidence the following note:—
"I recommend that the sewage be carried to the east shore of the Lower Hope below Gravesend, on the south side, so that the inlets at Cliffe would push it over to Mucking, from whence numerous outlets on both sides would carry it out to sea."

Captain Arthur Morrel, R.N., called in, examined by Mr. Morice.

648. I believe you are the captain of the "Cornwall" training ship?—I am.

649. You are in the Royal Navy?—Yes.

650. I believe you have been in the "Cornwall" for the last nine years?—Yes, for nearly nine years.

651. What part of the river is she lying in?—At Purfleet.

652. How long have you known the River Thames?—I have known the River Thames for 20 years and upwards, off and on.

653. Do you remember when the outfalls were opened at Crossness and Barking?—No, I was abroad at the time.

654. Do you remember the state of the river before that time?—Yes, I remember the state of the river very well.

655. Was the water used at all for drinking purposes before then?—Yes, about that time water used to be used for drinking from the Thames.

656. About what time?—About 20 odd years ago.

657. Before the time you are speaking of, what opportunity had you of knowing the river then?—I was residing at Erith, and used to go down with a bathing party sometimes of a morning, and a tolerably good bath one had in those days.

658. That is about 20 years ago?—Yes.

659. Is there any difference, as far as you have noticed, in the state of the river of recent years?—A very material difference.

660. In what way?—I consider it very much impurer.

661. To what do you attribute that?—It would be rather difficult for me to say. To impurities which are being emptied into it; that is what I should say.

662. Do you use the water of the river for any purposes on board the "Cornwall"?—Very seldom.

663. Used you to use it some years ago?—Yes, for washing the decks and for the boys bathing sometimes.

664. Have you altered that practice for any reason?—I have discontinued it for several years.

665. On what grounds?—Because it used to smell so bad that it was unhealthy.

666. What kind of a smell was it?—A sickening smell, arising from gases, it seemed to me.

667. Anything like a sewage smell?—I can hardly tell you that, for I have not been much in the vicinity of sewage.

668. At any rate you have given it up for the purpose of washing the decks and for bathing?—We very seldom use it for washing the decks; sometimes we might use it at the top of high water for the purpose of washing the upper deck, but never between decks, but just so as to save fresh water.

669. You have to use fresh water for the purpose of the decks and bathing?—Yes.

670. Where do you get the fresh water from?—From the Grays Waterworks.

671. Have you had any illness on board the "Cornwall"?—I had a very severe epidemic of typhoid in 1875–76.

672. Did that have any effect in inducing you to discontinue the use of the Thames water in the "Cornwall" at all?—That was one of the reasons which induced us to discontinue it, because we had two very eminent medical men from London to ascertain what had been the cause of the fever, and as they were unable to clearly discover it, we at all events thought we would discontinue the use of the water.

673. Since the time you left off using the Thames water have you had as much sickness on board as you had in previous years?—Certainly not.

674. (*Chairman.*) Have you had the same number of boys all along?—Very nearly; we vary. We have from 200 to 250.

675. (*Mr. Morice.*) Taking the percentage the amount of illness has been less since?—It has.

676. Can you tell us how much less it has been in figures?—I can hardly tell you in figures.

677. Can you not give it approximately?—We had two or three severe epidemics some years ago. We have had no epidemics for the last four or five years, although we have had one or two individual cases; in fact we had 10 or 12 cases three or four years ago.

678. Did those epidemics follow rapidly one after the other?—We had one in 1875 and 1876, and again in the following year and then afterwards, but not to so large an extent.

679. That would mean 1875, 1876, 1877, and 1878?—Yes, in 1877 and 1878 we had touches of fever; isolated cases.

680. (*Dr. Stevenson.*) And you have had 10 or 12 cases since then?—Yes, we have had 10 or 12 cases since then.

681. But you have had no really serious epidemic?—No, we have had no really serious epidemic; the water had not been entirely discontinued then. I have discontinued it the last three years entirely, but we used at first to leave it off here and there.

682. (*Dr. Chaumont.*) Have you had any cases since you have entirely discontinued the use of the water?—We have had isolated cases, presumably from a boy having touched the water, or tasted it, in cleaning out the boat or on shore.

683. Since you left off the use of the water have you not had a case of typhoid?—No, not since we left it off altogether.

684. (*Dr. Stevenson.*) So the 10 or 12 cases you referred to were not cases of typhoid?—We had 10 or 12 cases of typhoid about four years ago.

685. (*Mr. Morice.*) Do you feel any effect from the water?—Getting up in the morning I feel a sickness which I have been unable to account for. I presume there must be some cause for it, and I attribute it to the water.

*Capt. A. Morrel, R.N.*

1 Aug. 1882.

686. Do you know whether the smell of the water has been getting worse in recent years?—I should say it has been getting gradually worse every year.

687. Have you noticed the mud deposits upon the banks?—I have not had much opportunity of doing that, for I have much office work and I am very much shut up in my office on board.

Cross-examined by Mr. BIDDER.

688. Of course you are not a medical man?—I am not.

689. But you have, I presume, a medical officer on board the "Cornwall"?—We have one who visits every day or nearly every day.

690. Is that Mr. Netten Radcliffe?—No; he visited me two or three times.

691. What is Mr. Netten Radcliffe, is he a medical inspector of the Local Government Board?—I really do not know, he visited me two or three times.

692. Do you remember that after these epidemics you have mentioned Mr. Netten Radcliffe was sent down to inspect the "Cornwall" and to make a report as to the health of the boys?—Yes, I remember that very well.

693. Let me call your attention to the memorandum of Mr. Netten Ratcliffe on the reformatory school ship "Cornwall" addressed to Mr. Edward C. Seaton, M.D., Medical Department, and dated June 4th, 1878. I see he was directed by the Local Government Board to make an inquiry, first into the sanitary condition of the reformatory school ship "Cornwall" especially with reference to the recent prevalence of enteric fever among the boys, and secondly "into a suggestion "that the health of the boys probably suffered from "the outflow of metropolitan sewage into the river, "higher up the stream, at Crossness and Barking," do you recollect that he came down to make inquiries into these subjects?—I recollect his visits very well.

694. I will not read the memorandum at length, but I will ask you this, were you the captain superintendent at the time?—Yes, I was.

695. Let us see if you can confirm what he says here as this statement appears to be made with your authority. "But it is proper that I should offer some "observations on the opinion entertained by the "captain superintendent and others on the general "state of health of the boys. The captain superin-"tendent lives with his family on board the ship, and "has the boys constantly under observation. He "states that, except when infectious disease is intro-"duced among the boys from the shore by new "comers, there is great freedom from serious sickness, "and that even minor ailments are rarely trouble-"some"?—Yes, he is speaking of 1878.*

696. He is speaking in 1878, and I may take it he correctly reported your own observation and experience at the time, because he says he had it from the captain superintendent, that is yourself?—Yes.

697. That was correct at the time, was it?—I do not recollect at all what I said to Mr. Netten Radcliffe.

698. I suppose Mr. Netten Radcliffe would not be likely to have imagined that. Was it in accordance with your observations that there was great freedom from serious sickness "except when infectious disease is in-"troduced among the boys from the shore by new "comers"?—No, we very seldom do have any disease introduced by new comers, except itch or something of the kind.

699. But it is very strange that he should have said that if you had not told it him?—I do not recollect telling him anything of the kind.

700. Now is it correct to say that "minor ailments "are rarely troublesome"?—We have very little sick-ness as a rule.

701. He says upon the same page. "Thus from "the 22nd August 1876 to the month of May 1877 "there appears a succession of entries of 'sore throat,' "and 'tonsillitis,' in all 62 in number. In December "1876 scarlet fever appeared amongst the boys. "Fourteen cases of this disease, five cases of enteric "fever were sent from the ship to the Seaman's "Hospital, Greenwich during this month"?—And they all came back again with nothing the matter with them, all except three, I think.

702. That is very satisfactory. Now he goes into a good deal of statistics, and the desirability of more accurate records, and here I come to his conclusions. "With reference to the prevalence of enteric fever "among the boys in the 'Cornwall,' the inquiry had "particularly in view an examination of the circum-"stances under which a considerable outbreak had "occurred, beginning in September 1875 and ending in "January 1876. The state of the medical register, "and the absence of the medical officer who had charge "of the ship at the time, presented an insuperable "obstacle to my obtaining the details of the outbreak. "An investigation of it had, however, been made by the "medical officer of health for the port of London, Dr. "Harry Leach, during its progress," do you happen to remember that investigation?—I remember having several visits from Dr. Leach.

703. "The results of that investigation, as given in "his report for the half-year ending the 31st Decem-"ber 1875, contain the only account of the circum-"stances of the outbreak now likely to be obtained. "I have had several conferences with Dr. Leach on "the subject, and I concur with him in his con-"clusions and recommendations. The latter have "been substantially carried into effect by the school-"ship committee, and need not be further referred to "here. As to the origin of this outbreak of enteric "fever, I am of opinion, as the result of my own in-"quiries, that the disease was introduced into the ship "from the shore." Were you aware that that was the conclusion which the medical gentleman who inquired into the case arrived at?—I do not know that he came to any conclusion.

704. Did you never see this report before?—I do not think I did.

705. Did you never take sufficient interest to induce you to procure it?—I took, on the contrary, great interest in it.

706. I will read you a little more, because this will be news to you. "It may be accepted also, I think, "that a like origin is to be assigned to the several "prevalences of infectious diseases, including enteric "fever, which have occurred amongst the boys from "time to time. Under the present arrangements of "the ship boys are sent directly on board from the "original places of detention, without a precautionary "delay of sufficient duration to enable it to be ascer-"tained whether they may be in the incubative "stage of certain of the infectious diseases. Hence "the ship is at all times liable to have introduced "into it children sickening or about to sicken from "enteric fever, small pox, &c. Again, the ship has "no proper provision for the immediate isolation of "cases of infectious sickness, or of doubtful cases as "they occur. Such separation as can be effected on "board is futile for the purposes of isolation." Then he recommends quarantine and a place on shore. Next, he says, "The suggestion that the health of the "boys on board the 'Cornwall' may suffer from the "outflow of metropolitan sewage into the Thames at "Crossness and Barking appears to have arisen from "a conjecture that the recent prevalence of enteric "fever among them possibly had some connexion "with the pollution of the stream from this source. "I have already expressed the opinion that in the "outbreak of 1875–76 the disease was introduced "among the boys from the shore, and that the "malady, in the first instance, has at other times "been imported into the ship. Unable, from the "condition of the medical register, to approach the "question, as will be necessary before it can be com-"pletely solved, from a clear knowledge of the kinds "of sickness most apt to affect the boys, I have

* The witness, in correcting his evidence, denies having made the statement in the last part of this question.

" endeavoured to ascertain whether the condition of " the river at the point where the 'Cornwall' lies, " with reference to the flow of metropolitan sewage, " was such as to lead to the inference that the ship " was moored in an unwholesome position. I have " already stated that the 'Cornwall' lies off Purfleet." Then he describes the kind of ship, which I need not read. She "is moored close to the shore, 7 miles " below the metropolitan sewage outfall at Barking, " and 5½ miles below the sewage outfall at Crossness. " On the 18th August 1877, in company with Dr. " Harry Leach, I witnessed from the river the flow " of sewage into the stream. The day was peculiarly " favourable for observation. The surface of the " water was hardly disturbed, and then only at in- " tervals, by a gentle current of air from west-south- " west, so that it was practicable to follow the move- " ment of the sewage at the surface with the greatest " precision. It was about two hours of ebb tide when " we reached the Barking outfall. Sewage was " flowing thence in a broad, black, offensive stream, " carrying much floating nastiness on the surface. " The sewage hugged the near bank of the river until " it reached the mouth of Barking Creek, when it " was deflected towards the centre of the stream, " spreading out fanlike at the same time. The sewage " then flowed along mid stream, the current rapidly " breaking up and becoming dispersed, and a mile " below the outfall, opposite the powder magazine " just above the Crossness point, it was entirely lost " to sight, not even a trace of the floating matter " being discoverable, although several casts backwards " and foward across the river at this part of its course " were made in search of it. On approaching the " Crossness outfall three-quarters of a mile below the " point, where all trace of the sewage from the " northern outfall was lost to the sight, the odour of " sewage met the nostrils in advance, and the southern " sewage stream carried upwards in part by an eddy, " was entered a little above the outfall. The sewage " had the same aspect as that from the northern out- " fall. It hugged the southern bank in a broad well " defined current for three-quarters of a mile, then, " opposite the Belvidere Guano Works, it broke up " into several branches and spread out towards mid- " river, and a quarter of a mile below, opposite the " powder magazine there, all traces of sewage were " lost to sight." Does that agree with your own obser- vation, or have you anything to say to the contrary?—That is not at all my observation; those are Dr. Netten Radcliffe's observations, I think. I was not present, and do not know anything about them.

707. Then the memorandum goes on "On a sub- " sequent occasion (13th Oct. 1877), with the object " of ascertaining, if this were practicable, whether " the bed of the river where the 'Cornwall' is moored " was affected by the metropolitan sewage outflow I " collected specimens of mud from the bed of the " river inshore off the Barking and Crossness out- " falls, from beneath the 'Cornwall,' and from the " mud exposed at low water on the contiguous bank, " and from the bed of the river at Greenhithe at a " point between the 'Arethusa' and 'Chichester' " school ships lying there and the bank, seven miles " and a half below the Crossness outfall. For the " purpose of collecting these specimens the secretary " of the Thames Conservancy Board, Captain Burstall, " R.N., courteously put at my service the conservancy " steam yacht, and Captain James, the harbour " master, gave me his valuable assistance. The " specimens of mud collected off the Barking and " Crossness outfalls (that from Crossness being taken " from several points on an exploration rod, which " had been sunk over 10 feet into the mud bank, from " which mud was collected), and from beneath the " 'Cornwall' had the appearance and odour of " ordinary sewage mud. The specimen at Greentithe " had the appearance and odour of common river " mud as observed anywhere within the tidal stream. " These specimens were submitted to Dr. Dupré for " chemical analysis, and he added to them for addi- " tional comparison specimens of mud taken at low " water from the bank of the Thames at Vauxhall " Bridge and adjoining the Houses of Parliament. I " append Dr. Dupré's report of the result of his " analysis. It will be observed in this report that, " with one exception, chemical analysis failed to show " any material difference between the several " examples. 'They all consisted,' to use Dr. Dupré's " words, 'chiefly of sand, clay, and chalk, and con- " 'tained only a small proportion of organic matter. " 'This organic matter, moreover, seemed to be very " 'much of the same character in all, as shown by " 'the slight variations in the relative proportion of " 'carbon and nitrogen present in it. In fact only one " 'sample (No. IV., the sample taken from beneath " 'the 'Cornwall'), shows any material departure " 'from the mean in this respect. In this the pro- " 'portion of carbon to nitrogen is very much greater " 'than in the rest, showing the organic matter in it " 'to be of vegetable origin chiefly. This is due, no " 'doubt, to the admixture with it of an exceptionally " 'large proportion of disintegrated wood. In samples " 'I., II., and VII. (the first taken from the bed of the " 'river opposite the northern outfall, the second " 'taken from the mud bank, opposite the Crossness " 'outfall, and the third from the mud bank 50 yards " 'below Vauxhall Bridge, on the Surrey side), the " 'proportion of carbon is slightly below the average, " 'which may be taken as indicating a somewhat " 'higher proportion of animal contamination, due, " 'perhaps, to the presence in these samples of a " 'larger proportion of sewage deposit. As before " 'stated, however, neither the chemical nor the " 'microscopic examination lends much countenance " 'to the supposition that one sample consists more " 'than another of sewage deposit.'" Now, have you any observations or anything to contradict that?—With regard to the boys, in the first place, they are committed by the magistrates for sometimes three weeks or six weeks or more, generally a month before they come to us, so that they have not an opportunity of bringing anything into the ship.

708. They may catch it in gaol?—They have certi- ficates with them, and I have them examined.

709. Is that by the medical officer of the ship?—Certificates by the medical officer of the gaol, certi- fying that the boy has passed the examination, and is in good health.

710. But nobody can detect the infection in the earlier stages of incubation?—Not a single boy has had an infectious disease within a short time after his coming on board; we have never had a boy who has really produced an illness in the ship.

711. Mr. Netten Radcliffe comes to a directly con- trary opinion?—He cannot know so much about it as I can, or as my books will show.

712. I suppose you gave him all the information he required?—Certainly; he asked a great many ques- tions, and I gave him all the information within my power.

713. Next let me draw your attention to this. He says, "It is to be inferred either that the suspended " matters of the sewage which finds its way into the " Thames both above the metropolitan area towards " the source of the river, and below the metropolitan " area at Barking and Crossness, are equally dis- " tributed within the section of the river selected for " examination, or that each successive outflow of " sewage at the Barking and Crossness outfalls under- " goes so great a dilution and dispersion as practically " to become unrecognisable on the cessation of the " flow from any deposit of suspended matter it con- " tained. In either case sewage matter in solution " may be regarded as an almost inappreciable quantity " and ignored accordingly. It is not necessary for " the purpose of this inquiry to determine which of " these alternatives is the most probable. If the " former, there is no evidence to show that the posi- " tion of the 'Cornwall' off Purfleet is more unhealthy " than the position of any of the other school ships " on the Thames, and it is not known that the health " of the boys of any of the ships has suffered from " the position in which the different ships are moored;

*Capt. A. Morrel, R.N.*

1 Aug. 1882.

"if the latter, there is no evidence that the boys on "the 'Cornwall' are likely to be exposed to any "injurious influence from the outflow of the metro- "politan sewage at Barking and Crossness." Then I see he says this, and as you have said something about smells I will read it. "In the course of the "inquiry it was stated to me that at times much "disengagement of fœtid gas from the water about "the 'Cornwall' had been observed, particularly "when at very low tides the keel had happened to "touch the mud beneath her. I failed to get any precise "evidence as to this statement, but the phenomenon "has not been noticed during the time the present "captain superintendent has had charge of the ship;" is that correct?—I must say I have not smelt very much.

714. Indeed at the present time very little mud indeed lies beneath the ship, the greater part of the area of the river bed underneath being free from deposit.

715. (*Dr. de Chaumont.*) How soon after arrival on board ship has any boy ever been taken seriously ill, say with typhoid fever?—I do not remember any boy being attacked with typhoid fever who has lately come into the ship. I do not think the origin of it was brought from the shore.

716. Could you say at all the shortest time that any boy had been on board before having such an illness?—I could not at the moment, but I could furnish the statistics of it, because I have the particulars of the time of entry, and where they sleep, the nature of the illness, and so on.

717. Would they have been on board the ship any time before the illness?—Yes, some months.

718. (*Dr. Stevenson.*) Could we be furnished with Dr. Harry Leach's report?

719. (*Mr. L. Smith.*) He was medical officer of the city, and I have no doubt we can procure it.

720. (*Chairman.*) You spoke of having resided at Erith?—Some 20 years ago I used to go there off and on, my father was living there.

721. What length of time have you been there?—A month or six weeks at a time perhaps on coming home from abroad, or from Ireland, or from where I have been stationed.

722. And that extended over a period of some years?—Yes.

Re-examined by Mr. Morice.

723. Have you seen the report which has been read before?—I think I did when it came out, or read some parts of it, I think.

724. I understood you to say that you cannot agree with what it states there as regards the cause of the outbreak?—I do not think anybody knows really the cause of the outbreak. I do not think it ever was or could be clearly proved.

The witness withdrew.

Captain Frederick Walter, R.N., called, examined by Mr. Morice.

*Capt. F. Walter, R.N.*

725. I think you belong to the Royal Navy, and are in the "Arethusa"?—Yes.

726. I think you have been in the "Arethusa" for eight years?—Yes, since November 1874.

727. Where is the "Arethusa" stationed?—Off Greenhithe.

728. That is at the end of Long Reach?—Yes, between Long Reach and Fiddlers' Reach.

729. How long have you been acquainted with the river Thames?—Since that date.

730. Can you tell us during those eight years whether there has been any alteration in the state of the river to your knowledge?—Yes.

731. Has it been getting better or worse?—In my opinion it is worse.

732. During the last three or four years has it been very much worse or otherwise?—Worse, I think.

733. You say the river has been getting worse, do you remember when the fishing boats used to come up to Greenhithe?—Very well.

734. How long ago was that?—Four years; the last boat I think was three or four years ago.

735. (*Chairman.*) When you say fishing boats do you mean they used to fish there, or that they used to come up the river?—They used to fish there; in the autumn we used to have as many as from 15 to 20 boats catching shrimps and dabs.

736. (*Mr. Morice.*) Since that time have you seen any?—Four years ago there were about two, and since that time there have not been any.

737. Have you had any illness on board the "Arethusa" since it has been there?—Yes, we have had some.

738. Have you ever had any fevers?—We had typhoid fever between 1879 and 1880, not since then.

739. Have you been in the habit of using the Thames water for any purpose on board the ship?—We use it at present for washing the upper deck.

740. Used you to use it to any greater extent?—We used at one time to use it for all decks, until fever broke out in 1879.

741. And since the fever broke out in 1879 what have you done?—We discontinued using it from that time upon the lower deck, which was the sleeping deck.

742. May I ask for what reason you gave up using the water so much?—We were anxious to find out the cause of the fever, and as it struck me that using the water upon the lower deck would probably cause sickness, among other precautions, I discontinued it.

743. Was the water that you were using pure water?—No, decidedly not.

744. What then was the reason for your giving it up?—It was very dirty, and also if it remained upon the deck a short time it smelt very badly.

745. And therefore you gave up using it upon the deck where the boys slept?—Yes.

746. When do you find the water in the river is the worst; at what time of the year and of the tide?—In the hot part of the year certainly it is the worst.

747. And do you notice any smell from it?—Certainly, in hot weather and at low tide.

748. I believe you lie pretty close to the shore at Greenhithe; do you notice the mud on the banks at all?—We see it.

749. Has there been any greater deposit there of the mud lately, in the last few years?—I cannot say that.

750. Have you noticed the colour of it or the state of it?—I do not notice any alteration in the colour.

751. During the eight years that you have been there have you not noticed any alteration in the colour?—No.

752. (*Chairman.*) How far does your ship lie from low-water edge?—From low-water edge it lies about 80 yards.

753. (*Mr. Morice.*) How do you land at Greenhithe; is there a pier or a causeway?—A wooden causeway.

754. (*Dr. Williamson.*) Is the water clean enough for boys to bathe in at your ship?—We bathe at the top of high water only; at low water it is too dirty. I do not let them bathe except at the last quarter of the flood or the first quarter of the ebb, so as to get the water at its freshest.

755. (*Mr. Morice.*) Is that a recent alteration which you have made?—No, I have always done that.

Cross-examined by Mr. Michael.

756. If I rightly understand it is at low water that you smell something bad?—It is not only at low-water but it is principally at low water.

757. How much of the mud is exposed at that time?—That is a matter of opinion; I should say 150 yards, but I do not know exactly.

758. Do you know what the characteristics of Thames mud are in respect to smell?—They are very bad.

759. Do you know that it smells worse than any other mud?—I know it has a very bad smell.

760. Do you know whether it is the water or the mud of which that peculiar sweetness is the special characteristic?—I have not discovered any sweetness about it, but I should say that the mud is the worst.

761. How do you discover that?—If I go out upon the stern walk when the water is stationary I smell it more than if it is running.

762. I will ask you this. Does not it suggest itself to your mind that if the water is very impure, and it is stirred up, you would be more likely to recognise the impurity by the smell than if it were perfectly still?—I do not think it follows if there were any breeze blowing.

763. But a breeze would ruffle the water?—It would take the smell away from the ship.

764. Not if it were blowing towards the ship?—It must be blowing away from the ship in one direction.

765. And also by parity of reasoning it must from one direction be blown across the ship. Now what is the general health of the boys?—Very good.

766. What is the number of boys on board?—313.

767. What is the mortality among the boys?—I do not remember exactly, but I keep a record. Last year we lost two. This year so far we have lost none.

768. At what age do they enter?—From 13 to 17, and they go up to 19.

769. What is the average?—15 years.

770. What did the two boys die of?—One died of consumption; they both died in hospital. As a matter of fact, we did not keep them on board.

771. What did the other one die of?—He died from some affection of the lungs.

772. Do you think that was occasioned by the quality of the water or the smell?—No, I should not say that.

773. The last year before that how many were there died?—Two.

774. Have you had any cases of scarlet fever?—No.

775. Or diphtheria?—No.

776. Have you had any cases of enteric fever?—That I believe is something like typhoid.

777. Yes, typhoid fever. How many cases have you had of that?—We did have an epidemic of that three years ago. We had 17 cases, and before that we only had isolated cases.

778. Over what period did the 17 cases range?—Nine months.

*Capt. F. Walter, R.N.*

1 Aug. 1882.

779. (*Chairman.*) How long ago was that?—It broke out in 1879, and the last case was in the summer of 1880.

780. (*Mr. Michael.*) What step did you take with regard to them?—We sent those who were ill to the hospital.

781. Did you take any steps to discover whether there was any special cause for the breaking out of typhoid fever?—We took every step to examine into the origin of the outbreak.

782. With what result?—We never discovered what it was.

783. What has been the condition of the water since?—I have not noticed anything different.

784. What sort of health do you personally enjoy?—Very good.

785. Is it principally during the warm weather that you noticed the smell?—Yes, in the hot weather.

786. The river bank is exposed at that part of the tide in the summer to the heat of the sun?—Yes, but it smells both at high and low tide.

787. Have you had any experience of the mud of the Thames in hot weather at any other part of it than where the ship is lying?—No.

788. Or any other river?—Yes, I have lain in other rivers.

789. What others?—The Canton river.

790. That is not a very sweet smelling river is it, or the mud from it peculiarly salubrious?—Hardly so.

791. Can you say whether you would like to be anchored during the whole of the year upon the mud of the Canton river?—I cannot say that I should like it.

792. What do you think would be likely to be the effect upon the health of 300 boys of being anchored for a year upon the mud of the Canton river?—Leaving other things out of the question, I do not think that they would be worse than being in England.

793. Leaving what other things out of the question?—The climate generally.

Re-examined by Mr. Morice.

794. I understand you to say however that in the last two or three years you have not had much illness, as you have discontinued using the water upon the lower deck?—Yes.

795. The outbreak of the fever was when you were using the water upon the lower deck?—We discontinued it when the fever broke out.

796. Since that time you have had no cases?—We have had no cases since that outbreak ceased, and that lasted over about nine months.

797. That was in the summer of 1880?—Yes.

The witness withdrew.

Captain Arthur Gillett, R.N., called in, examined by Mr. Morice.

798. You belong to the training ship "Warspite"?—I do.

*Capt. A. Gillett, R.N.*

799. Lying off Woolwich?—Yes.

800. How long have you been in the "Warspite"?—Nearly five years.

801. During that five years have you noticed the state of the water in the river?—Yes.

802. Can you tell us whether it has been altering either for the better or worse?—I do not think it has varied.

803. Have you noticed as to whether the water is in a pure or an impure state off your ship?—Just now it is very clear.

804. During the last two or three years can you tell us what has been the condition of it?—For a month in the middle of the summer, generally in July, it has been very bad; the water becomes slate-coloured, and great masses of black mud come up from the bottom and spread all over the surface.

805. (*Chairman.*) Has that been so this summer?—No, not this summer yet.

806. (*Mr. Morice.*) But the last two or three years has it?—I did not notice it the first year I was there, which was the summer of 1878, but in all the succeeding summers it has been very bad indeed, the smell is perfectly dreadful.

807. At night time do you take any precaution with regard to the ports?—I am obliged to close all the ports, and keep the deck under the hammocks wet with disinfectants.

808. (*Chairman.*) For how long during the season is that your practice?—For about a month as a rule.

809. (*Mr. Morice.*) Is that from July to August?—It all depends upon the state of the weather; it has been in June and part of July; it was in July last year.

810. (*Chairman.*) Have you adopted that practice every season since you have been on the ship?—No, I have only done it once, that was last July.

811. (*Mr. Morice.*) At what time of the tide do you notice it worst?—At all times of the tide. I do not think it makes any difference.

812. Have you noticed it very much worse at all in the last few years that you have been there?—I think it was worse last year, if anything, than it was the two years before; that is to say, it was worse for a short time, but it was not at its worst above three weeks last year.

813. Do you know the river and the operation of the tide up and down below your ship?—No, I have only a general knowledge of the tides.

814. Have you ever had any of the Thames water analyzed at all?—Yes, two years ago I took some samples and sent them to Dr. Collingridge.

815. That is the medical officer for the port of London?—Yes; he reported that it was "slightly diluted sewage."

*Capt. A. Gillett, R.N.*

1 Aug. 1882.

816. Where were these samples taken from?—They were taken from mid-stream right in the middle of the river.

817. Near the ship?—Opposite the ship.

818. Have you ever had any illness on board since you have been there?—Every July and August until last year we had isolated cases of typhoid fever. One year we had three cases and the other one each, and we could not account for them in any way except from the state of the river.

819. Have you used the water of the river for any purposes at all on board the ship?—We use the water for the purpose of washing the upper deck in the winter, and for washing the boys, but not now, not in the summer.

820. Why have you discontinued?—Because of the bad state of the water in hot weather.

821. (*Dr. Williamson.*) Is the water ever used for washing your kitchen utensils?—Yes.

822. In summer as well as in winter?—No, we do not use any river water in summer, when it is in a bad state; but just now we are using it for the purpose of washing the upper deck at high water.

823. (*Mr. Morice.*) Do you occasionally lift your mooring chains?—Yes; last year we parted one of the mooring chains, and the conservancy replaced it, and my attention was called by their officer, Mr. Wood, to the state of the cable, pointing out that it was all covered with sewage.

824. Did you see that?—Yes, he called my attention to it. I went on board the lighter to see it.

825. Do you find that there is anything peculiar in the state of the boats or the oars which there was not before?—When the river gets slate-colour, which it does in the summer, the oars and the blades all turn black, but it has not been the case yet this year. Two days ago the river began to smell, but the last two days it has gone off again. The river began to change colour a few days ago, but it is clearer now again on account of the cooler weather.

826. Could you tell us, if sewage is put in about Woolwich, or Crossness, or Barking about high water, how far you consider it would go upon an ebb tide?—It might go 15 miles perhaps, but I do not speak with any authority upon that point.

827. Of course you are at Woolwich, that is above Barking and Crossness?—It is three miles above, I should think; I have not measured it.

828. And you find the sewage comes up to there?—Yes, it comes up to us; the whole bed of the river I believe is covered with it. It sinks, and when the temperature rises to a certain point it rises with it. It appears as if gases exploded in the bed of the river, because it comes up and spreads all over; it comes up in great masses of black stuff, sometimes as big as this room.

829. (*Chairman.*) At what time of the tide is that especially observable?—At all times of the tide when the river has that peculiar slate-coloured appearance.

830. Without being disturbed?—Without apparently being disturbed in any way, and it is worse when the steamers pass, at low water especially, because they stir it up.

Cross-examined by Mr. MICHAEL.

831. Is it your theory that the floating particles of sewage in the tide are deposited at the bottom of the river?—I think they must sink partially.

832. Especially if they have gas attached to them?—My theory is that they are at the bottom; that the whole bed of the river is nothing but sewage.

833. But let me examine your theory; do you tell the Committee that it is your impression that bodies specifically lighter than water sink to the bottom?—No, they would not if they were specifically lighter than water.

834. Did you ever examine the sewage passing into the river?—No.

835. Even if the particles were heavier do you think that in the flood of the river they would fall at once?—Yes, if they were heavier they would, I think.

836. Whatever the velocity of the stream?—Yes, I presume they would sink.

837. Now, you have stated that a piece of chain was covered with sewage; how did you discover that it was sewage?—My attention was called to it by the man who was at work.

838. But your mind would be very slightly affected I presume by the fact of your attention being called to it; now what made you think it was sewage?—By the smell.

839. But have you never seen the bottom of a pond into which there is no sewage discharged?—No.

840. You have never seen these black masses, some of which come to the surface?—No.

841. You have never studied the phenomena of the bottoms of ponds?—Never.

842. Where did you ever see river mud which did not smell badly?—I have seen it.

843. Where?—If I were to take the river mud off the bank at Woolwich it would not smell probably.

844. Do you not know that it is the characteristic of the Thames mud that it does smell very badly after a time?—No.

845. Have you taken any samples?—Only during one month.

846. How do you know that it only smells in that month if you have only taken it at that one time?—I know I can smell it 30 feet above the level of the water.

847. That is to say, the banks of the river under a hot sun give off a bad smell?—There is no bank of mud close to the ship. It is washed away there.

848. Is there no bank near your ship?—No, unless there is a ship lying there which banks it up; but if there is no vessel at the breaking up yard, close to the "Warspite," the tide washes it away.

849. Now as to the sewage upon your chain. Is it your opinion that the sewage has been washed out of the outfalls, and has gone down the river and come back and deposited itself upon that chain?—Yes.

850. How many boys have you under your charge?—200.

851. What is your mortality?—The boys are remarkably healthy.

852. What sickness have you?—Just at the present we have seven boys down, but they are with cuts and bruises and things of that sort.

853. Will you eliminate those and take the rest?—We have no sickness beyond that.

854. What is the average age of your boys?—They come in between 13 and 16, and they stop about a year; the average age would be 15.

855. Mortality nil, and sickness consisting only of cuts and bruises?—Yes.

856. (*Chairman.*) Where is your ship?—Near Charlton Pier; we are exactly off the western end of the dockyard.

857. (*Dr. Stevenson.*) With regard to the samples you have spoken of as being diluted sewage, at what time were they taken?—They were both taken at the last quarter of the ebb, before flood.

858. (*Chairman.*) When was the cable you have referred to taken up?—Last year.

859. Do you recollect whether the river was low at the time?—I think it was in September, but I am not quite sure, and about low water.

Re-examined by Mr. MORICE.

860. At the time when you saw these gases, or large pieces of black coming up to the surface and spreading, was it very hot weather?—It was.

The witness withdrew.

Adjourned to Friday next at half-past 1.

# THIRD DAY.

## Friday, 4th August 1882.

PRESENT:

SIR JOHN COODE IN THE CHAIR.

PROF. ALEXANDER WM. WILLIAMSON, Ph.D., F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E.
WM. POLE, ESQ., F.R.S., *Secretary*.

4 Aug. 1882.

861. (*Mr. Lumley Smith.*) At question 718 of the notes, the Commission asked whether they could be furnished with Dr. Harry Leach's Report, which had been referred to by Mr. Netten Radcliffe, in his memorandum which was read to you upon the last occasion; I have that report before me, and am prepared to read it if the Commission would wish.

862. (*Chairman.*) If you are going to examine upon the report you had better read it, as we should like to have it upon our notes.

863. (*Mr. Lumley Smith.*) This is dated :—

"Port of London, Sanitary Offices, Deptford, S.E.,
"GENTLEMEN, November 12th 1875.

"IN accordance with instructions received at your last meeting on the 11th ultimo, I have the honour to submit a detailed report as to the origin and progress of an epidemic of enteric (typhoid) fever that has recently occurred on board the reformatory school ship 'Cornwall,' moored off Purfleet.

"Having received early information of the outbreak from Captain A. Morrell, the Superintendent of the ship, and also from the authorities of the Seamen's Hospital at Greenwich, I visited the vessel on the 7th ultimo.

"From evidence adduced, it appears that, as long ago as the 14th of September a boy named Edgecumbe, employed to assist the cook in the galley, was attacked with the disease, was affected with it three or four days at least before admission into the sick bay, was in the sick bay five or six days, and was eventually removed to the Seamen's Hospital. Before removal from the deck on which he ordinarily slept, with other boys, to the sick bay, he used the common closets in the bows by day, and the movable pan or pail on the deck at night, and during his stay in the sick bay he used an ordinary fixed closet in the bay. This closet discharges into the river by a distinct pipe, the lower end of which is usually above the water line. He had been on shore in Purfleet village five days before the commencement of his illness, and there had tea without milk and bread and butter.

"No further cases occurred until the 2nd of October (*i.e.*, 18 days after the first case), when Mr. Glen Bott, surgeon to the ship, pronounced three of the boys affected, on the following day, two, and on the 4th several more. On the 6th 20 boys were under treatment at the Seamen's Hospital, on the 12th a total of 38 cases were reported; on the 25th six cases were taken to St. Bartholomew's Hospital; and on the 27th and 28th 41 pronounced and suspected cases were removed to your hospital ship 'Phin,' and placed under the care of Dr. Whitcombe. Although the epidemic manifestly declined on or about the 1st instant, a total of 79 cases have up to the present date occurred out of a complement of 261 persons, one of these cases being the carpenter of the ship. One death only is recorded.

"It is evident from the foregoing history that this outbreak must have been due to a common cause, and thus must be sought for in the atmospheric surroundings or in the food or drink. It is right, too, to premise that the epidemic may have been set in motion by the boy Edgecumbe.

"On the morning of the 8th ultimo, accompanied by Mr. Glen Bott and one of the officers, I made a thorough inspection of the ship, commencing at the keelson. The water in the pump well was quite sweet, but there were several small pools of water in the neighbourhood of the keelson that were strongly impregnated with sulphuretted hydrogen. All the water tanks in the main hold had been very recently lime washed, and appeared clean and in good order, but the three foremost on the starboard side contained a considerable amount of deposit. All these tanks are connected. All parts of the ship below the lower deck appeared fairly ventilated, except a small space forward in front of the magazine, which was damp and very 'stuffy,' having no visible means of ventilation when the hatchway is closed. The air of the main hold has free access to the inhabited decks through the hatchways, which are covered only by wide rope network.

"The larger half of the boys sleep on the lower deck, on which there are no fixed closets, and which is entirely clear fore and aft, except a small range of officers' cabins on each quarter, and a storeroom aft. The in-cast ventilation is effected by means of wide tubes, that brings the air from the side scuttles in at the bottom of the deck, the hatchways acting as upcasts. On midnight visits paid to this ship, both in summer and winter, I found the deck very well ventilated. Large buckets are used as urinals, and the contents are emptied next morning into the latrines above.

"The smaller half of the boys sleep on the middle or 'mess' deck, in which also there are no fixed closets. There is a somewhat objectionable sink on each side of the deck in connexion with the washhouse (which is forward), and a small tank amidships, into which water is pumped from below, and from which the boys and officers derive their drinking water.

"There are on the main deck forward three fixed closets flushed by Thames water from a tank above; two of these are always under lock and key, and the third, above mentioned, is in the sick bay, which sick bay is inconveniently situated for efficient ventilation, being close to the galley, and so necessarily bulkheaded to the upper deck. It remains but to record that the closets or heads are in the usual position at the bows, on a level with (or strictly speaking, somewhat below) the upper deck, and although the inclines below the seats are steep, the closets are imperfectly emptied and cleansed by a tolerably frequent flushing by water pumped from the river direct into the trough.

"It is not necessary here to particularise the scale of diet, but it is proper to record that no milk is given, that all water used in the galley is drawn from the same source as the drinking water supply on the mess deck, and that the boys are said to drink, as a rule, a very large quantity of water at frequent intervals. The water supply is obtained from the Grays Waterworks Company, and the main from which it is drawn is about 12 miles in length, and supplies, before it reaches Purfleet, several villages and a large number of isolated houses. The 'Cornwall' supply had, until the outbreak occurred, been drawn from a small pipe connected with this main, and sent direct, by means of an ordinary hose, over the bank into an open boat, conveyed in bulk in this open boat from the shore to the ship, and then pumped into the tanks.

4 Aug. 1882.

This boat in the intervals of work is moored at the ship's side, close to the galley scupper, and not far from the discharge pipe of the sick bay closet. It is important to notice that the adjacent foreshore is frequently covered with decomposing sewage, brought by a strong ebb tide from the metropolitan main drainage outfalls at Barking and Crossness.

"Having regard to the above facts, it is abundantly evident that the water might have been fouled from several sources after it has left the shore, and before it is discharged into the tanks of the ship. Two analyses that have been made separately and independently prove this to be the case, inasmuch as they show that the water taken from the tank on the mess deck contained a large amount of organic nitrogen, that it contained more than three times as much organic matter as the water obtained from the standpipe on shore, and was wholly unfit for drinking purposes.

"I did not, therefore, wait for the results of further investigation, but at once submitted the following recommendations to the authorities of the 'Cornwall' for immediate adoption, having previously had the advantage of an interview with Dr. Buchanan on the subject at Whitehall:—

"(1.) The shore water pipe to be carried to a point immediately opposite the ship, and a flexible hose (attached to a light chain cable) to connect this pipe directly with the tanks on board.

"(2.) Pending this arrangement tanks to be used in the water boat.

"(3.) All tanks on board the ship to be emptied, refilled, and charged with Condy's fluid.

"(4.) The hold, and all places under the lower deck, to be fumigated at least two successive days with sulphur and charcoal.

"(5.) The space in front of the magazine, above referred to, to be ventilated.

"(6.) All water 'settlings' near the keelson to be sponged out and charged with carbolic acid.

"(7.) All fixed closets on the main deck forward to be abolished.

"(8.) The present heads to be removed, and others substituted, the troughs of which should be lined with slate; the troughs to be partly filled with water and emptied at regular intervals, or (as I think better still) supplied with a small but constant stream of water from tanks fixed in the hammock nettings, or elsewhere above.

"(9.) To alter, at an early period, the present position of the sick bay, so that some amount of ventilation may be secured by leaving the bulkhead about waist high.

"I have since recommended:—

"(*a.*) That the ship should be entirely vacated for at least a fortnight in order that a thorough examination and cleansing may be made.

"(*b.*) That one of Crease's filters shall be placed upon the mess deck in lieu of that now in use, through which all water used for drinking purposes shall pass.

"(*c.*) That the drinking water shall also, if possible, be boiled.

"The last two recommendations were made because appended results of the analyses proved that the water, even as received from the shore, is not free from sewage contamination, and the enclosed copy of a letter from Professor Abel, of the War Office, confirms the statement. The inquiry, therefore, is incomplete until the exact locality of contamination of the water is found. But there can be little doubt as to the harmful influence of the metropolitan main drainage outfalls having regard to the fact that the ship is very close in-shore, and is moored fore and aft, and, moreover, that a majority of the boys affected messed on the starboard or shore side of the ship.

"It appears very desirable that an exhaustive official investigation should be made into the quality and conveyance of the water supplied by the Grays Company, so that the exact locality of its pollution may be ascertained, and with this view I have to suggest that a copy of this report be sent to the Local Government Board for the information of the medical officer.

"I am, gentlemen,

"Your obedient servant,

"HARRY LEACH."

Then there are two analyses of water.

864. (*Mr. Michael.*) Now in order to make this outbreak of fever complete I hold in my hand a report to the Local Government Board which definitely settled what this fever was. This is Mr. W. H. Power's report to Dr. Buchanan of the Medical Department, dated March 15th, 1880, Mr. Power being sent down by the Local Government Board in order to investigate the epidemic on board the ship "Cornwall."

865. (*Mr. Lumley Smith.*) Is that the same epidemic, the one I have been reading about is in 1875, this seems to be a different affair altogether.

866. (*Chairman.*) I understand the report of Dr. Leach's is made in November 1875.

867. (*Mr. Bidder.*) Then I think that must be the same epidemic as the one I read the report upon from Mr. Netten Radcliffe; but I understand there have been two outbreaks, one that of 1875, which my learned friend Mr. Lumley Smith has read Dr. Leach's report upon, and upon which apparently the Department sent down Mr. Netten Radcliffe; and one in 1879, and my learned friend Mr. Michael will read the report in regard to that.

868. (*Mr. Lumley Smith.*) I am in the hands of the Commission, but we have not heard anything of an outbreak in 1880.

869. (*Mr. Michael.*) Yes, we have the Captain Superintendant of the "Cornwall" speaking to it.

870. (*Chairman.*) Let us have it altogether, make it as continuous and connected as you can. Was this particular report referred to by the officer of the "Cornwall"?

871. (*Mr. Michael.*) I do not know that he did refer to this particular report, but he referred to the outbreak to which this report had reference.

872. (*Mr. Bidder.*) At question 684, in answer to Dr. Stevenson, he said that he had 10 or 12 cases of typhoid fever about four years ago, that was in 1878.

873. (*Mr. Michael.*) Now here is the report upon these cases of typhoid, and I have merely cut out those portions of the report which are specially applicable on account of the various matters, (I will put in the report for the Commission to see), which the Captain Superintendent mentioned with regard to the use of water impregnated with sewage, which is the matter before the Commission.

874. (*Mr. Lumley Smith.*) If the Commission wish to have a report of this sort, one does not wish to stand in the way of its going upon the notes, but one is unable to ask any questions about it not having seen it before its going upon the notes.

875. (*Mr. Michael.*) Nor could we with regard to Dr. Leach's.

876. (*Mr. Lumley Smith.*) That was furnished because it was brought in by Mr. Netten Radcliffe's report.

877. (*Mr. Michael.*) The report states:—

"In regard of possible influence of river-borne sewage, bathing and swimming of the ships' company in the river, and washing of decks with river water, received attention. As to bathing, all hands bathed for the last time for the season on the 15th of August. Only boys learning to swim, some 24 in number, continued their lessons until the 8th September. Bathing seems to be excluded as a factor in the outbreak from the circumstance that the interval between the occasion of the last bathing and the date of the outbreak, a period of upwards of five weeks, far exceeded any known limit of the incubation period of enteric fever. On the other hand

swimming, though not thus excluded, was set aside from the fact that one only of the 24 boys learning to swim was included in the first group of sufferers by the outbreak."

Now we come to what was mentioned by the Captain Superintendent, viz., the washing or sluicing of the decks with Thames water.

"Washing, or rather sluicing of decks with river water, could not as a possible cause of the outbreak be excluded, but on the other hand there was nothing whatever to show that it had in fact any influence for harm. And so with any emanations, there may have been from the river itself, or from the foreshore."

Then on page 5 the Report continues:—

"The animal food of the boys though varied day by day (fresh meat four times a week, and cheese, suet pudding, and salt meat each once), was the same every Sunday, every Tuesday, every Wednesday, every Thursday, every Friday and every Saturday; but on Mondays could vary. Monday was indeed always a boiled *salt meat day*, but the *sort* of salt meat consumed on Mondays differed from week to week. As a rule it was alternately salt beef and salt pork, now and then it happened that either one or the other constituted dinner on *successive* Mondays, and occasionally a dinner of the one was supplemented to some extent by the other."

878. (*Chairman.*) Do you think that this part of the report is material.

879. (*Mr. Michael.*) I shall show that it is most material. Then the report proceeds—

"Salt beef, therefore, and salf pork came under suspicion, for either of them might by this method of consumption have been related to the grouping of the graver cases on or about certain Tuesdays; and further it was ascertained that a fresh cask of each came into use shortly before the outbreak. Suspicion of this sort once aroused settled naturally on pork. Not indeed on account of so-called typhoid fever of the pig (which is not known to be transferable to man), but for a wholly different reason. It occurred to me that if pork had had to do with the outbreak, some of that (224 lbs.) of the cask newly taken into use *might have been trichinised, and that the disease therefore from which the boys suffered might not have been enteric fever at all, but trichinosis.* It will be observed that a theory of trichinosis seemed exactly to fit the conditions assumed as requiring fulfilment. A newly broached cask of pork came into use shortly before the occurrence of the outbreak. The pork was consumed by the boys alone. Portions of the pork not thoroughly well cooked might form but a small proportion of a total dinner for the boys, and might therefore have been comsumed on particular days within the limits of one or two messes, and thus (if such portions happened to be infected with trichina) the incidence of the severer cases on a particular mess or messes might have been brought about. Again, pork might very well have been consumed on two successive Mondays, and after that, not until a fourth Monday, and thus the specialties of the time distribution of cases, notably the peculiar grouping of the graver attacks, might be accounted for, while the great diversity of duration of illness would be quite intelligible. Trichinosis in its incubation period, and in the duration of the illness resulting from it, has been known in outbreaks of the disease upon the Continent to vary very greatly. Probably the persons who have eaten most largely of trichinised flesh, or who have eaten it in a condition most nearly approaching a raw state, suffer soonest (sometimes within 24 hours), and most severely from trichinous disease. Many persons who have certainly partaken of trichinised flesh, but who have done so sparingly or in a fairly cooked state, have escaped the disease altogether, or have had merely trifling illness of undefined commencement and end, and occurring many days, even some weeks after the infective meal. Other evidence, too, seemed to support the theory. It was now ascertained that the use of pork on board the 'Cornwall' had, owing to misgiving as to the wholesomeness of such food, been discontinued shortly before the cessation of the outbreak; further it was learned that the pork in question was 'American pork,' exceptionally obtained from a firm in Bristol; and more, that it consisted solely of 'belly pieces,' and therefore of parts of many pigs, and of those parts most likely to be infested with trichina."

Then it goes on with regard to the theory and with the clinical records, and then on page 7 the report proceeds:—

"It was now, upon reaching this point, that it came to be pretty clearly seen that an outbreak, characterised as this one was in the bulk of its cases by simple continued fever with gastero-enteric disturbance, might just as well have been related to trichinosis as to enteric fever, the fact of certain of graver cases of the outbreak taken collectively presenting most of the symptoms characteristic of enteric fever seeming to lose significance beside the circumstance that these very same cases presented, collectively, many symptoms that might be referable so trichinosis. So that at this stage of inquiry it had become obvious that need for direct evidence respecting the nature of the outbreak had become imperative, and in this sense I reported to the medical officer of the Board."

Then he says what has specially directed his attention to the matter, and I ought to tell you that only one boy of this number died during this so-called "epidemic of enteric fever." Then the report proceeds:

"Application was therefore made by the Board to the Home Office for an order for exhumation of the body of Pierce."

That was the boy who died.

"An order being granted conditionally on consent of the friends of the boy being first obtained, and on the understanding that the exhumation and necessary re-interment of the body should be carried out under the auspices of the Sanitary Authority of the district in which burial had occurred, I set myself to procure this consent and to make the requisite arrangements. This having been done, the examination of the body took place on the 6th December. With the consent of the Board, Dr. Cory (who had previously assisted in microscopic examination of the pork) was associated with me at the necropsy, and in the pathological investigations which followed."

Then he goes on to state what are the appearances, and how much they found the body better, and with less decomposition than they had expected. Then the report goes on.

"Further examination was carried out conjointly by Dr. Cory and myself. I think it right to put on record minute technical details,"

and so on, with respect to the examination, especially with regard to enteric fever. I need not trouble you with that, you will see it does not arise upon this point. Then the report proceeds:—

"More thorough examination of the mesenteric glands than had before been practicable revealed a few only enlarged, and none were bigger than peas. The other organs afforded no evidence for or against enteric fever. It thus appeared after detailed examination of the viscera habitually implicated in enteric fever as had appeared from the original necropsy, that with

4 Aug. 1882.

all allowance for decomposition, no such anatomical changes as are characteristic of enteric fever toward the end of the third week of its duration were to be found, and the conclusion now seemed warranted that whatever had been the nature of this boy's fatal illness it certainly had not been enteric fever.

"This conclusion was more than confirmed by the results of microscopic investigation conducted with reference to trichinosis. In the very first specimen examined, a few fibres from one of the abdominal muscles, was found a wandering and living trichina, and further search revealed the presence of these parasites in most of the muscles examined. Although tolerably abundant the trichinæ could not be said to infest (in the common sense of the word) any of the muscles, except, perhaps, the diaphragm, and in none of them had the parasite reached the stage of encapsulation. Except the first found no trichinæ exhibited active movement, and comparatively few had attained, as had that one, their full growth as muscular parasites. In specimens of this sort the internal structure and organisation were under a high power ($\frac{1}{12}$) readily made out, the parasites having altogether resisted decomposition, and most of them having probably died only a short time before examination. The smaller, not fully grown muscular trichinæ, on the other hand, had seemingly all long since died. Their outline had become indistinct, their interior granular, and their structure could not be made out. Many were found broken up. Examination of the decomposing contents of the small intestine failed to find any parent trichinæ, but by scraping the under surface of the folds of mucous membrane of the bowel, brood trichinæ in considerable numbers were obtained. These had apparently all died, and their structure could not satisfactorily be made out.

"Doubt could no longer exist that this boy died from acute trichinosis. Not only was the presence in his body of the actual parasite demonstrated, but the results of microscopic examination pointed to the parasites as having played a very active part in the production of his illness, and were, indeed, precisely such as might have been anticipated in a case of early death from trichina disease. Death took place in this instance on the 18th day after appearance of symptoms, at a period that is too short to have allowed of universal migration of brood trichinæ, and insufficient also for the attainment of full growth in the muscles of any but early migrants. At the same time the period was not nearly long enough to have sufficed for the full evolution and encapsulation of many (if indeed of any) muscular parasites."

Then he goes on to demonstrate where they were found in small quantities in the diaphragm and elsewhere, and comes to the conclusion, as demonstrated clearly, that all doubts were entirely cleared up, that all these so-called cases of enteric fever were due to the eating of insufficiently boiled pork owing to the mode of cooking which they observed, that is to say, putting the pork into boiling water, so that the outside of the pork became covered with such a coating of fibrine as would not allow the water to penetrate into the interior; and they clearly make out that this so-called enteric fever was really a series of attacks of the disease known as trichinosis, the parasites being traced in the muscles.

880. (*Chairman.*) I gather that Mr. Power expresses no doubt of this particular case being due to trichonosis, but does he say that all the cases are due to trichonosis?

881. (*Mr. Michael.*) I will read you the head-note, "Mr. W. H. Power's Report to the Local Government Board on an outbreak of fever that proved to "be Trichinosis on board the Reformatory School Ship "'Cornwall.' George Buchanan, Medical Department, March 15th, 1880,"

882. (*Mr. Lumley Smith.*) I find by the report of Dr. Collingridge that a post mortem was held upon a boy who died in 1880, and that post-mortem proved beyond all doubt that the boy died from typhoid fever, so that it must not be assumed that every case was due to this trichinosis.

883. (*Dr. de Chaumont.*) Were you aware of the remarks of Professor Cobbold upon that case, as that would be found to bear upon the question. Professor Cobbold did not believe that the animal or specimen found was the real trichina.

884. (*Mr. Balfour Browne.*) He made it out to be an entirely new species, if it were a case of trichonosis at all.

885. (*Mr. Michael.*) It is quite clear that all the symptoms which are diagnostic of enteric fever were absent from the boy who was said to have died from enteric fever. The body not having been in such a state of decomposition as to prevent identification of the whole of the parts, the condition of the peritoneum and of the mesenteric glands, the absence of ulceration of the mucous membrane, being points diagnostic of the disease, and ulceration of the bowels not being the cause of death, all point to its not being a case of enteric fever.

886. (*Mr. Abernethy*). Do you read that with regard to Captain Morrell's evidence?

887. (*Mr. Michael.*) Yes.

888. (*Mr. Abernethy.*) But he does not go so far as 1879.

889. (*Mr. Michael.*) He was rather loose in his answers. He does not specify dates particularly.

890. (*Mr. Balfour Browne*). There is no reference in his evidence to the precise epidemic that Dr. Power was reporting upon.

891. (*Mr. Morice.*) I think it was referred to in the report of Dr. Harry Leach.

892. (*Mr. Michael.*) This will make it clear. This report says, "This inquiry was directed by the Local "Government Board at the request of Mr. Secretary "Cross, to whom application had been made (30th "October 1879) by the School Ship Society for "investigation of an alleged outbreak of fever on "board their ship 'Cornwall.'" This outbreak it was stated had occurred about a month before and was the second prevalence of fever on board within a period of four years. At the end of 1875, indeed, nearly 50 per cent. of the boys had been affected with what was held to be enteric fever. In regard of this outbreak, and also at the request of Mr. Secretary Cross, an inquiry was in March 1877 ordered by the Local Government Board. It was to have reference to the sanitary condition of the "Cornwall," and to a suggestion that the health of the boys had suffered from the outflows of metropolitan sewage at Crossness and Barking. Mr. Netten Radcliffe conducted this inquiry but for various reasons was unable to complete it. A memorandum by him presented to the Board on the subject is dated May 1878. That clearly shows that the whole history of the matter was before them of the two outbreaks of 1875 and 1879.

893. (*Mr. Lumley Smith.*) But the report is headed 1880, and the whole that my learned friend has read is dealing with the outbreak of 1879.

894. (*Mr. Bidder.*) The report clearly shows that this was the second oubreak which Captain Morrell was referring to.

Mr. WILLIAM EGERTON called in, examined by Mr. MORICE.

*Mr. W. Egerton.*

4 Aug. 1882.

895. I believe you are surveyor to the Erith Local Board?—I am.

896. And you live at Erith I believe?—I live at Belvidere now. I did originally live at Erith.

897. For how many years did you live at Erith?—I lived for 21 years at Erith, and $5\frac{1}{2}$ years at Belvidere.

898. How far is Belvidere from Erith ?—A mile and a half.

899. Have you known the state of the river during all that time ?—Yes, I have.

900. I believe you have an office near the river ?—I have, within 10 yards of it.

901. Can you tell us whether during the years you have mentioned there has been any alteration in the state of the river as far as the low-water mark is concerned ?—There has been a very great alteration.

902. It has altered during those years ?—Yes, it has very much.

903. In what way ?—The buoy that was put down by Captain Burstal at the lower ballast wharf, of which I was manager for 21 years, and which was put down at low-water mark ;—

904. (*Chairman.*) What was the object of the buoy, to mark a shoal ?—No, it was a ballast wharf and this was the mooring buoy for the vessels. There were I should say two buoys, they were put down from instructions by Captain Burstal, the lower buoy in 9 feet of water at low water, and the upper in 14 feet.

905. At what date would that be ?—I should think it would be 18 years ago. I cannot quite remember the date.

906. (*Mr. Morice.*) You say the river is altered ; in what way is it altered ?—The lower wharf buoy frequently lies aground, and the water recedes from it some yards, and the upper wharf buoy is frequently aground.

907. Has that been so long ?—I have noticed it the last four or five years, but it gets worse every year.

908. (*Chairman.*) When did you first notice any change ?—I daresay it would be 8 or 10 years ago.

909. What first called your attention to it ?—Because the vessels that lay moored to this buoy could not swing round.

910. (*Mr. Morice.*) Have those buoys ever been moved at all ?—No.

911. You say there is a difference of water from what there was when they were first put down ?—A very great difference.

912.—Can you tell us whether you remember when the outfalls were opened ?—I should think it was 16 or 18 years ago.

913. Do you remember the state of the river before that time. Have you noticed any alteration in the state of the river as far as the colour of the water or anything else is concerned ?—I have noticed a very great alteration.

914. What has been the alteration which you have noticed ?—With respect to the colour of the water, I have noticed the water coming out of the outfalls at different times, and I could see it and trace it down as far as Erith by the different colour.

915. (*Chairman.*) Are you frequently upon the river below Erith ?—No.

916. You do not know what happens there ?—No, not below the district of Erith.

917. (*Mr. Morice.*) Is there any smell or otherwise from the water ?—Yes, a very bad one at times ; when the wind is off the water very bad indeed.

918. What sort of smell is it ?—It is a very peculiar smell. I can only compare it to this, when a cesspool has been emptied two or three days it would smell somewhat similar to what that would smell if it had not been disinfected and cleansed.

919. At what time of the year is that the worst ?—In the summer ; in the warm weather.

920. At what time of the tide ; could you tell us that ?—I should think about half ebb.

921. You are inspector of nuisances, are you not, for the Erith Local Board ?—Yes.

922. And in the course of your duty as such, do you visit the factories upon the river ?—Yes, on the south side of the river, and once or twice I have visited them upon the other side.

923. (*Chairman.*) Does your jurisdiction extend to the other side of the river ?—No.

924. (*Mr. Morice.*) Whereabouts are these which you speak of ? on the south side ?—Yes. If you wish to have them in detail, the first one is about half-way between Erith and Crossness, that is Messrs. Callander and Son's Bitumen Works.

925. That is upon the south side ; how far above Erith ?—Three-quarters of a mile ; those are bitumen works. That is a smell similar to what you get from asphalting in the streets of London.

926. What is the next above that ?—Messrs. Charles Price and Company's Oil Works.

927. (*Chairman.*) Do they refine the oil ?—Yes, they refine the oil.

928. (*Mr. Morice.*) It is engine oil, is it not, that they manufacture ?—They prepare different kinds of oil, and the smell from that is like as if you were enclosed in a small room and half a dozen candles were hung up and blown out.

929. What is the next ?—That is Messrs. Berger, Spence, and Company.

930. (*Mr. Michael.*) Is that the Bellevue Guano Company ?—No, that is done away with.

931. (*Mr. Bidder.*) What are they ?—They are the manufacturers of a particular metal called Spence's yellow metal.

932. (*Chairman.*) Is that offensive ?—No.

933. How would you describe that smell, what is it like ?—There is scarcely any smell from that. The next in our district is Collins' Glue Works ; there is a little smell there, more especially at particular parts of the operation. The next is Procter and Bevington's.

934. Have you yet come up to Jenningtree Point ?—No, not yet. Procter and Bevington are scutch boilers. They boil the refuse they bring from the tanyards.

935. That is the refuse of skins ?—Yes.

936. (*Mr. Bidder.*) What do they make of that ?—They extract the fat from it first and make manure of the refuse. The next is Johnson and Company. I have not been to see their works. It has not been long opened.

937. (*Chairman.*) What process do they carry on there ?—A chemical manure manufacture.

938. (*Mr. Michael.*) Those are the fish manure works.

939. (*Chairman.*) Is that also below Jenningtree Point ?—It is at Jenningtree Point. There is nothing else till you come to the Arsenal.

940. But we were told before that the principal works were between the two magazines.

941. (*Mr. Morice.*) They are just above Jenningtree Point ?—They are nearly all below. Messrs. Price and Callander's are nearer Erith than the others.

942. (*Chairman.*) Then, at any rate, the bulk of them, according to your description, is between Jenningtree Point and Erith.

943. (*Mr. Michael.*) Jenningtree Point is between the two groups. Price and Callander's are below, and the other four the witness has given are above Jenningtree Point.

944. (*Chairman.*) That corresponds with what other witnesses have said.

945. (*Mr. Morice.*) Have you visited all those factories ?—Yes.

946. Did you distinguish the various smells from them ?—Yes.

947. Is the smell you have told us of which comes from the river anything like any of the smells from the factories ?—No.

948. Are you able to say that it is a different smell altogether ?—It is a different smell altogether.

949. Do any of the factories you have mentioned discharge anything into the river ?—Yes, there is one which comes from Messrs. Price's, which is called the "Common Sewer Ditch," that discharges partly into the river.

950. Do you know any other ?—I do not know any other.

951. With regard to those you have visited upon the other side have you noticed smells coming out from these factories ?—A little.

952. Are you able to say whether the smell coming

*Mr. W. Egerton.*

4 Aug. 1882.

from them is like the smell coming from the river?—It is not like it at all.

953. Do you remember whether there was any fish in the river at that part?—Yes, there was.

954. How many years ago would that be?—That would be 24 or 25 years ago. I have caught many myself.

955. Up to what time do you remember fish being caught at all there?—I remember some eels being caught three years ago, picked up upon the mud, they seemed in a dying state, but other fish I have not known caught there for the last seven or eight years.

956. Do you know anything about the Dutch eel boats whether they come up there?—They used to come up to Erith, but they do not come there now, that was the place they always used to come to.

957. Where to?—Erith, off the Crown Wharf.

958. That is in Erith Bay?—Yes.

959. Do you know why they do not come up there now?—Because the water is so bad the fish cannot live.

960. *Mr. Bidder* objected to the evidence as not being within the witness's own knowledge.

961. (*Witness.*) I also know it from being on board the eel scoops, and I have seen them picking the eels out of the well, and saying they could not keep them alive.

962. (*Chairman.*) How long ago was that?—Eight or nine years ago.

963. (*Mr. Bidder.*) What have you seen?—I have seen them picking the "dropped eels," as they call them, out of the water, saying they could not keep them alive.

964. (*Mr. Morice.*) As a fact you know this, that at any rate the Dutch boats do not come up and lie off Erith now?—I do.

965. Could you tell us anything from what you have seen in the river as to the course the sewage takes in going down the river?—It depends so much upon the state of the tide.

966. I will give you the ebb tide, take the top of the ebb, what course would it take going down from Woolwich as far as Erith?—I do not go with my district further than Crossness, but from Crossness I should say a great deal of it goes down the centre of the river.

967. Do you know from your own knowledge how far it would go down upon a whole tide?—I do not know that.

968. (*Chairman.*) The witness has already said that he did not know the river below Erith.

969. (*Mr. Morice.*) Do you know the state of the banks about Erith?—Yes, I do.

970. Has there been any alteration upon them of recent years?—In what way do you mean; do you mean stoning them?

971. In any way?—There has been a large quantity of work done in stoning on both sides of the river.

972. Is there any difference in the way of deposit of mud?—Yes, a great difference.

973. In what way?—In the increased deposit of mud. If you are down by the Corinthian boat house between half ebb and half flood you will see vessels swinging round in the reverse way to what they would in the stream, and often fouling their anchors.

973*a*. (*Mr. Morice.*) Do you know Church Hole?—Yes, it is a little above that I am speaking of.

974. Have you noticed any difference in the colour of the mud that is deposited?—Yes, I have; it is very much darker.

975. Is there more of it about there than there used to be?—Yes, very much.

976. Have you noticed any smell from the mud deposited at low water?—Yes, when the sun is out very hot and the wind is off the water it smells very bad, and I have noticed it when there is a fog. I live upon the hill, and when I am half way down the hill, about from 70 to 80 feet above the level of the water, I get into the smell, and it seems as if I could not get out of it. You can get out of the factory smells, but out of the smell of the river you cannot get, and a very nauseous and unpleasant smell it is.

977. What time of the day are you now speaking of?—About 8 o'clock in the morning when I am coming down.

978. Have you or any of your family ever suffered any illness from this?—Yes.

979. (*Mr. Bidder.*) From what?—From the smells arising from the river, and from living in close proximity to the river. I took my wife to four physicians in less than a fortnight so that I should get the best advice. I saw Dr. Kidd and Dr. Peacock in Finsbury Circus, Dr. Jervis in Thames Street, and Dr. Palfry, and they all advised me to take my family away from the river, which I have done.

980. When was that?—Seven or eight years ago.

981. At what time of the year?—In summer time.

982. (*Mr. Bidder.*) Perhaps Mrs. Egerton is delicate?—Not at all so.

983. (*Mr. Morice.*) Could you tell the Commission anything further with regard to the sewer ditch you have spoken of from one of the factories?—No, I could not.

984. What is it?—It is only a ditch that runs into the marshes, and they turn half their refuse into it before it gets to the river.

985. Is it a sewer?—It was one of the old sewer ditches; it used to drain the marsh.

986. (*Chairman.*) Although called the sewer ditch, are we to understand that it only takes the sewage from these particular works?—It goes through the marshes.

987. It is a marsh drain?—It is a marsh drain.

988. But receives the outfall from these works?—From Messrs. Price's works.

989. (*Mr. Morice.*) It is a ditch or drain going through the marshes?—Yes.

Cross-examined by Mr. Bidder.

990. Let us begin with the health. In the first place can you tell me this: your Erith district is remarkably healthy, is it not?—I believe it is very healthy, as healthy as any of the surrounding neighbourhoods.

991. I believe that the medical officers' reports show a remarkable absence of epidemic disease and a remarkable low death rate?—It is below the average.

992. And in other respects it is a peculiarly healthy district?—I believe it is; some parts of it are much more healthy than others; if you get on the high land it is much more healthy than near the river.

993. Dr. Jessett is your medical officer, is he not?—Yes.

994. Did you see his last report upon the health of the district?—I did.

995. I think he pointed out an extraordinary diminution in the number of deaths?—I believe he did.

996. And a total absence of all epidemics?—I do not know that I could go as far as to say that there was a total absence of all epidemics.

997. But *he* went so far as to point out a total absence of all epidemic, and I see that typhoid fever appears to have been confined to one district, Northumberland Heath; that is a high district is it not?—Yes.

998. Away from the river?—Yes.

999. So that your only case of typhoid fever was upon the high ground and away from the river?—Yes.

1000. How far is Northumberland Heath from the river; any considerable distance?—Yes, nearly two miles.

1001. Now about the Dutch eel boats; do you know when the Dutch eel boats ceased to come up to Erith?—I should say it was eight or nine years ago.

1002. Are you right about that?—As I said before I cannot be sure as to dates.

1003. It is suggested to me that they have not come up to Erith since 1850?—I am sure they have. I was not at Erith at that time.

1004. Possibly that may be so?—I know I have gone on board of them often, and got eels from them many times.

1005. And you cannot say how long ago?—I cannot.

1006. Now about the remarkable smell you have observed off the river, does it come off the mud or off the water?—Off both.

1007. And you have endeavoured to convey an idea of it, which I confess is a little confusing to my mind, that it resembled a cesspool which had been emptied a certain number of days, do you mean that it is not so strong as it might be?—It is not so pungent as it would be if it had been freshly opened, it would be a little more flat.

1008. I see you formed a sort of olfactory scale, a cesspool one, two, three, four, five, six, or seven days emptied. I do not know what would be zero in such a case?—Nor do I know. I have had very little to do with them.

1009. Do you know Johnson's fish manure factory?—I do.

1010. In your opinion how many days of a cesspool being emptied would represent the smell from Johnson's fish manure factory?—I do not know, because since the inspector has been appointed under the Alkali Act I have not gone round inspecting them.

1011. How long ago was that?—Two months ago.

1012. Were Mr. Johnson's works in existence then?—Yes, they were, but they were altering them.

1013. You have not been inside since they have been at work?—Not recently.

1014. Do the scutch boilers carry on their works still?—Yes.

1015. Have you been inside them?—I have many times.

1016. Is it an agreeable smell?—Not at all, but I would rather have that than the smell from the river.

1017. In what direction was the wind when you smelt the smell from the river?—North-east.

1018. You know there are works upon the other side of the river, do you not?—Yes.

1019. Have you smelt them?—Yes, I do a little sometimes, there are some works just opposite, Proctor and Bevington's.

1020. There are Wilson's chemical manure works, do you know them?—I know them by looking across the river at them.

1021. Do you know them by the nose?—Yes, I have smelt them a little sometimes.

1022. Among other things they produce a great deal of sulphuretted hydrogen, do they not?—I do not know what they produce.

1023. (*Chairman.*) Those are above Cold Harbour Point?—They are, one just below Rainham Ferry and one just above.

1024. How would they be with regard to Little Cold Harbour Point?—They would be here (*pointing to the map*), there are two below Rainham Ferry and four above it.

1025. Miller and Johnson's chemical manure works are a little farther down, do you know them?—Those that I refer to are below Rainham Ferry.

1026. Do you know a third factory below that where they make fish manure?—There was one, but it has been closed, whether it is open or not now I do not know.

1027. How long ago was it closed?—It was closed last summer. I went over with Mr. Ogsden to see it.

1028. You have never gone over particularly to see what it was like when it was working?—No.

1029. Do you know just by Rock Ferry there are gas purification and chemical works?—There is one I know but I have not been inside of it.

1030. Do you know Barnes's chemical factory, a little back from the river?—I do not.

1031. Do you know Talaman's chemical works?—No, I do not go over on that side.

1032. Do you know Messrs. Crossfield's works?—Yes, I know Messrs. Crossfield's, but what they do I do not know.

1033. Now how long have you noticed this two days' old cesspool smell?—For five and a half years since I went as surveyor to the board.

1034. But you have been in Erith many years; had you never noticed this two days' old cesspool smell till then?—I smelt it more particularly then.

1035. Within what limits would you have smelt that?—From Johnson's works as far as my district goes beyond towards Crayford. That would be going to Erith, and then turning along the main road to Crayford.

1036. But, taking it along the river, it would be from Johnson's works to Erith?—Yes.

1037. When did you smell it last?—I do not remember; but we have not smelt it so much lately, the wind being westerly. We have had such a continuation of westerly winds that we have had very little smell.

1038. When do you recollect smelling it last?—I could not say. I did not make any memorandum of it.

1039. This year?—Oh, yes.

1040. How long ago. If it is this year you could recollect it. Are you quite sure you have smelt it this year?—Yes, many times. I think the time when I smelt it the worst was in March.

1041. You have not smelt it lately?—I have not.

1042. Have you been to Erith lately?—I go every day.

1043. The last day or two you have had a north wind, have you not?—We have had a little north wind the last two or three days. It depends upon the state of the wind. If it is a strong wind it blows it further away; but if it is a dull heavy day we get it much worse.

1044. I think you said you had seen the water coming out of the outfall?—I have.

1045. And how far have you traced it?—To Erith. I could distinguish it by the colour as far as it ran down the river, and not only the colour, but the streamage as it is called, the corks and things of that sort which go along each side.

1046. You would see the corks?—I do. I could see the colour of the water too.

1047. You would not expect the corks to sink after a mile, would you?—No, certainly not.

1048. (*Chairman.*) Does this discoloration extend over the whole of the river?—No.

1049. Over what part?—Over the centre part more especially.

1050. (*Mr. Bidder.*) Over what part of the river, proportionately, would you see the discoloration?—Over about an eighth part of the river.

1051. When did you see it last when you traced it down to Erith?—In June.

1052. And you traced it in a definite stream as far as Erith in June; were you in a boat?—No, I was on the river bank.

1053. How near the bank was the stream?—Nearly in the centre of the river.

1054. You could see from the shore the distinguishing line or boundary of the sewage in the centre?—It was more defined near the centre in the upper part than it was further down.

1055. So I should suppose. Was it defined at all at Erith?—I did not say at Erith. I said I traced it as far as I walked down, but it was visible at Erith.

1056. And there was no smell?—There was smell.

1057. You said the last time you smelt it was in March?—There was a little smell when I have seen it at other times.

1058. But you say this time, as I understand, hat there was no smell?—This time there was not.

Re-examined by Mr. Morice.

1059. As I understand you the smell depends upon the direction of the wind and also the state of the weather?—Yes, certainly.

1060. You say you have had westerly winds?—Yes.

1061. And has the weather been so very hot as it has in other years?

*Mr. W. Egerton.*

4 Aug. 1882.

1062. It is in hot weather that you have found it worst?—It is.

1063. You inspect these factories in the ordinary way. Have you had to inspect them specially lately?—No.

1064. (*Chairman.*) With regard to the inspector that you spoke of just now, is he inspector of nuisances?—No, he is inspector under the Alkali Act.

1065. But I thought you gave us to understand to a certain extent that your duties had ceased in consequence of the appointment of this inspector?—That was so.

1066. You acted as inspector of nuisances as well as of factories?—Yes, I did.

1067. (*Mr. Morice.*) Now after the appointment of this inspector have the factories been to your knowledge better or worse?—They have been very much better, but this was early in the spring, when I had special instructions to go and see them.

1068. (*Mr. Bidder.*) Was that in consequence of special complaints?—It was.

1069. Made by whom?—By some of the inhabitants.

1070. (*Mr. Morice.*) You inspected them, and was any action taken by the board?—No, only notices were given and some alterations were made in the machinery, in the condensers and furnaces.

1071. (*Chairman.*) Was that in consequence of the report you made to the board?—It was.

1072. (*Mr. Bidder.*) Will you let us have that report?—I can no doubt find a copy of it.

1073. (*Mr. Morice.*) Since that time have the factories been better or worse?—They have been very much better.

1074. You have told us that the smell from the factories is quite distinct from the smell from the rivers?—It is.

1075. Now you have told my learned friend that when you have got upon high land you are all right; have you personally got upon the high land lately; do you live higher up than you used to?—Yes.

1076. Is the part where your house is upon very high ground?—Yes it is 170 feet above high-water mark.

1077. And have you felt the evil effects which you did before?—I have not.

1078. (*Mr. Bidder.*) When was your inspection of these works?—I do not remember the date, but it is some time since Christmas.

1079. Was it this spring?—Yes, this spring.

1080. Was that in consequence of the complaints from the inhabitants of Erith?—Yes, it was.

1081. Were those complaints that the works were a nuisance?—That the smell was a nuisance.

1082. To the Erith people?—Yes, to some of them.

1083. Was there anybody else called in to report besides you?—Yes, Mr. Ogsden, a chemist and expert.

1084. And you found it necessary to order alterations in their machinery and arrangements?—Yes.

1085. In other words you found their complaints well founded?—There was a smell which ought not to have occurred; there was a smell, and it was stronger than it should have been.

The witness withdrew.

Mr. Michael Hind called in, examined by Mr. Morice.

*Mr. M. Hind.*

1086. I believe you are an auctioneer and undertaker?—I am.

1087. And a member of the local board of Erith?—I am.

1088. How long have you resided at Erith?—I have resided at Erith all my life excepting the time that I have been away at school.

1089. I believe you are now somewhere about 50 years of age?—I am 54.

1090. Do you live near the river?—I do.

1091. Can you tell us whether there has been any alteration in the state of the river during the last 20 or 30 years?—There have been great alterations since the opening of the outfall.

1092. You remember that?—I do.

1093. Do you know what the river was like at Erith before the outfall was opened?—It was much purer than it is now; there was not so much sediment.

1094. Has that been very different the last few years?—It increases every year, I consider.

1095. (*Mr. Bidder.*) What has increased every year?—The sewage.

1096. (*Mr. Morice.*) Do you remember whether the water used to be drunk some years ago?—I do; I remember it well.

1097. Can you tell us how many years ago that was?—I should think it was 14 or 15 years ago that it would be drunk; it might, possibly, be even less than that.

1098. (*Chairman.*) Where was the water taken from?—It used to be drunk, or at least used for culinary purposes off Erith; and higher up, say towards the Pool, it used to be drunk.

1099. Taken from the centre of the Thames?—Taken from the stream; the ships used to fill up their "breakers" and take them to sea with them.

1100. (*Mr. Bidder.*) Is not the water brackish at Erith?—It may be a little brackish at very high water; quite high water.

1101. (*Chairman.*) Not at low water, I think?—No.

1102. (*Mr. Morice.*) Will you tell us at what part of Erith you live exactly?—I lived directly on the causeway.

1103. Have you noticed in recent years any difference in the causeway?—It has been lengthened very much.

1104. Could you tell us how much?—More than 100 feet; I should say quite 100 feet.

1105. When was that done?—It has also been raised; it has been made 3 feet 3 inches higher.

1106. When was it altered and lengthened?—It has been added to 20 feet at a time, perhaps, within the last seven or eight years; perhaps the first 20 feet might have been put on eight years ago.

1107. For what reason?—Because the mud grew up so much around it that the causeway was entirely covered. It used to extend only 300 feet, and now it extends more than 400 feet; it is also 3 feet 3 inches higher. When it was 300 feet long there used to be about 6 feet of water at the end of this causeway; in the lowest part of it there used to be a foot side; the towest part of it was where the stone causeway and the wood causeway joined, there used to be a dip there, but still there used to be a foot side to it. It was afterwards considered necessary to run a bridge from the wood portion of the causeway to the stone causeway, so that persons could go along it, and I should say it has been lengthened by degrees about 100 feet. The banks used to be exceedingly steep just outside the causeway. Although there were only 6 feet of water at the causeway end, it used to drop suddenly to 12 or 13 feet of water. There used to be a large yacht drawing 10 feet of water which used to anchor within about 20 yards of the causeway end when it was 300 feet long; she used to swing there and never ground. Now that very portion where she used to lie is quite out of water and dry at low spring ebb. You cannot get to the end of the causeway now that it is 102 feet longer, by two boats' length, by at least 30 feet. On Wednesday last it was quite 30 feet from the causeway end.

1108. (*Chairman.*) You mean it was dry 30 feet from the end?—It was dry.

1109. (*Mr. Morice.*) Has that been so for the last few years, or how long has it been accumulating?—It has been accumulating ever since the southern and northern outfalls were opened, by degress gradually getting more and more.

1110. (*Mr. Michael.*) In the last 15 years?—It may be 16 or 17 years. I do not know exactly when the outfall was opened; I know it was the same year as the explosion, and that was 16 or 17 years ago.

1111. (*Mr. Morice.*) Have you noticed that very much more lately?—It keeps increasing, in fact the causeway at the present time is covered with mud; I was there this morning at 8 o'clock, it was covered with mud even then.

1112. As you have seen it as late as this morning, what kind of mud is it that covers it?—Black stinking mud.

1113. And with regard to the mud deposited upon the banks, has that altered of late years?—It is all the same; the mud that washes over the causeway is the same as that on the bank, because the bank is on a level with it, and the mud washes over the causeway.

1114. Is that the same kind of mud?—It is exactly the same kind of mud.

1115. Has that deposit of mud been going on also for the time you mention, namely, the last 15 years?—It has. At the end of the causeway there must be at least 10 or 11 feet perpendicular of solid mud or muck.

1116. Have you found any smell coming from the mud or the river?—I have.

1117. And what sort of smell is it?—A very unpleasant smell; it is a smell very much resembling a cesspool, a cesspool that may, perhaps, have remained open for some few days; not so strong as if the crown of the cesspool was only just taken off, but supposing the cesspool had been exposed to the air for three or four days, this has about the same smell with it.

1118. Have you noticed the smell much this year?—I have not noticed the smell so much this year as I did last year.

1119. Can you tell me why that is?—Because the summer has not been so hot, that is my impression, and I think there has been also more rain.

1120. When is the worst time of year that you notice it?—In hot weather and when there is a wind from the north (north-east) or east, whenever the wind is touching upon our shore we get the smell of the river very bad, it comes up with the wind, and particularly in foggy weather.

1121. The smell then depends a good deal upon the state of the wind?—It does, because the drift of the wind of course blows it over our shore.

1122. Do you remember whether any fish used to be caught in the river off Erith?—A very great many.

1123. How many years ago would that be?—I do not suppose there has been any fish caught there for eight or ten years.

1124. When do you remember fish being caught there?—I cannot exactly say as to the time, but at one time, before the outfall was opened, a very large quantity of boats used to lie from Church Hole over across towards Rainham Ferry, and they also used to lie in Aveley Bight.

1125. Where is Aveley Bight?—On the other shore, just above Purfleet; and by degrees after the outfall was opened those men have gone down lower and lower, until now they have got down to Lower Hope.

1126. That is to say they have gone from Church Hole gradually to Lower Hope?—Yes simply because their occupation was gone, there being no fish for them to catch.

1127. Do you remember the accident to the "Princess Alice"?—I do.

1128. Did you have to do with a good many of the bodies that were brought ashore?—I did, with 29.

1129. They were brought ashore at Erith, I believe?—They were.

1130. (*Chairman.*) Where was it exactly that the "Princess Alice" came into collision?—Just above the northern outfall.

1131. (*Mr. Morice.*) About what is termed "Tripcock Point"?—Yes, about Tripcock Point, between North Woolwich and Halfway Reach.

1132. Several bodies you say were brought ashore at Erith?—They were.

1133. And I believe you attended to them?—I did.

1134. Can you tell us the state in which you found them?—I found a great many of them, those that had been in the water any time, say three or four days, in a very dirty filthy state.

1135. Was there any smell from their clothing or otherwise?—All their underclothing was saturated with perfect muck, their pockets and everything of the kind, all their clothing was in an exceedingly dirty state, no one would ever think they had been in the water so short a time to see the dirty state that they were in.

1136. Was there any smell from them?—Yes, an offensive smell.

1137. Have you had to do with bodies that were drowned in the river years age?—Yes, with a very great many.

1138. Before the outfalls were opened, I mean?—Yes, years before the outfalls were opened; I had to do with the "Worcester" accident, those boys were drowned very close to where the outfall now is, when the outfall was building.

1139. There were 11 of them, I believe?—Yes, there were 11.

1140. They were brought to Erith, I believe?—Yes.

1141. In what state did you find their bodies—They were much cleaner than those that were drowned in the "Princess Alice" disaster.

1142. I may ask you generally with regard to bodies that were taken out of the water and put under your care before the outfall was opened, what state were they in?—The clothing and the bodies generally were much cleaner than they have been since, and it is feasible, because by rolling about in a lot of black mud they must get in a very bad state.

1143. Have you ever bathed in the river?—Yes, many a time.

1144. Have you bathed in it lately?—No, I should be very sorry to.

1145. Can you tell us whether there is anything else in which there is a difference between the mud which is on the banks now and what there used to be?—There is a very great deal of difference in the colour at the present time, and there is a very great difference in the quantity; at one time you would go to the water's edge and get no more mud than just a little over your ankles, whereas now if you were to go to the water's edge it would be over your middle.

1146. (*Dr. Williamson.*) What was the colour of the mud formerly?—It was a lighter colour than it is now.

1147. (*Mr. Morice.*) Used there to be a smell from it like there is now?—There was not an offensve smell like there is now; not anything at all like it.

1148. Do you know the smell which comes from the factories?—I do remarkably well.

1149. Is the smell which comes from the factories anything like the smell you have told us of that comes from the water?—It is perfectly different, people who have been living any length of time in the neighbourhood can detect the factory works smell directly, and also they can detect the smell from the river.

Cross-examined by Mr. Michael.

1150. Is the smell from the factories all alike?—No, it is not all alike.

1151. Are you able to discriminate from which of the factories the smell comes?—I am able to tell whether a smell is from a factory or from the river.

1152. That is not the question I ask. I asked you whether you could tell from which of the factories the smell came?—Yes, I can in some cases; there is the asphalte manufactory which you can tell directly. Then again Price's candle factory has the smell of a candle burning down in the wick or in a candlestick.

1153. That is not pleasant, is it?—Not particularly. Then there is a manufactory of guano.

1154. That is pleasant no doubt?—But it does not smell like the river.

*Mr. M. Hind.*

4 Aug. 1882.

1155. None of them smell like the river?—None of them are so bad.

1156. The faint smell from the river is much worse than the guano factory or the burning of a candle down in the stick?—Not at all; the river is the worst.

1157. You are a distinguished taster and tester of smells apparently?—I have had much experience.

1158. You have had experience no doubt, and you have confined your evidence to the southern side?—I have spoken of the works upon the other shore as well.

1159. You are a member of the local board of Erith?—Yes, I am.

1160. And the last witness is your inspector of nuisances?—He is.

1161. And you appear to have compared notes with him before coming here?—Not at all.

1162. It is curious that you should both have hit upon the same simile of a cesspool open for so many days. Now you say the smell is more particularly distinguishable when the wind is from the north-east?—From the north.

1163. The wind from the north would bring to your discriminating cognisance the smells of the factories upon the river?—It would bring the smell of the factories to Erith.

1164. Of those upon the other side?—Of those upon the other side as well as these.

1165. Now do you know a gentleman named Crossfield who has manure works on the north side?—I do not.

1166. Do you know the candle factory upon the other side nearly opposite Price's works?—I do not know that. I know there are works, but I do not know them particularly.

1167. The Rock Portland Cement Company?—I do not know their works.

1168. Messrs. Salaman's works, the gas purification works, Messrs. Miller and Johnson's chemical manure works, and the fish manure works; in fact, there are altogether nine works an the north side, and their smells would be brought directly, supposing they had any smell, across the river with a north wind to you; have you ever taken pains to ascertain whether any smell came from any of those nine works?—We have taken pains as far as the local board is concerned with regard to the smell coming from them, but it is a very different smell to the smell from the river.

1169. Then there are smells from them?—No; as far as those upon our own side are concerned, we have taken steps with regard to them to prevent the evil.

1170. But a north wind would blow direct from the north shore to you?—No, it would blow right over us from our own side.

1171. Kindly apply your mind to the question. Would it not blow directly over you from the other side of the river?—You have made a mistake about the bend in the river.

1172. Now all these factories on the other side are out of your jurisdiction?—They are.

1173. And you have never smelt any bad smell coming from them?—They have no doubt a smell coming from them as well as from the others.

1174. When did you smell them last?—I do not know whether I have smelt them. I cannot tell them one from the other; but as far as the factories upon this side go, I can distinguish between them which is which.

1175. I understood you to say you never smelt them upon the other side?—I do not know what they are.

1176. You have positively told the Commission that when the north wind blows a certain bad smell has its origin in the river. Now I put it to you that upon the coast opposite to your place there are nine works giving off bad smells?—They are not at all opposite to us, they are very much farther up.

1177. (*Mr. Abernethy.*) They do not appear to be opposite to Erith.

1178. (*Mr. Michael.*) A dead north wind would blow the smell from Wilson's works, Miller Johnson's chemical manure works, and the fish manure works. They are directly in a line with Erith.

1179. (*Witness.*) But you said directly opposite Erith.

1180. (*Mr. Michael.*) They are directly opposite as far as the north is concerned, if you were drawing a line?—I should say it is three miles from Erith Causeway up to either of these factories. They are a long way above Erith altogether, upon the opposite side of the river.

1181. (*Chairman.*) It is apparently more like two miles.

1182. (*Mr. Michael.*) It is a mile and a quarter. I have measured it upon the Ordnance map. Here is the church (*pointing to the map*)?—But the causeway is half a mile from the church.

1183. It is a mile and a quarter from the causeway to the fish works upon the opposite side of the river?—I should have thought it would have been much more.

1184. As a member of the Local Board of Health did you several months ago direct your inspector of nuisances to inquire into complaints which had been made to you as to the smell arising from the manure and other works within your own jurisdiction?—Yes, he was appointed to do so.

1185. But you had had complaints previously with regard to these works?—Yes; but that did not apply to the works upon the other side of the water.

1186. Can you apply your mind; I said within your jurisdiction?—Yes, there was complaint.

1187. Could you furnish the Commission with the complaints that were made which gave rise to that action which was taken by the Board?—I cannot say now.

1188. Were they brought before you officially as the urban sanitary authority?—I believe they were.

1189. Is a record of them to be found in the books?—No doubt there is in the minutes.

1190. Would you kindly allow us to see the complaints that were made, and what was done in consequence of those complaints?—As far as I am concerned, you are quite at liberty to do so.

1191. Having paid so much attention to the mud which is deposited on the causeway, have you paid attention to the flow of the river in the last 15 years?—Yes, I have.

1192. Has it in any way changed, in your opinion?—There is a very great change off Erith now as far as regards the current.

1193. Where does the current go now?—The current is further out in the stream than it used to be.

1194. Is it not deflected out towards the other shore?—Do you mean the flood or the ebb?

1195. Take the ebb.—The ebb tide just after high water sets down to about opposite Rainham, and then off into Erith Bight, and then down to Aveley Hole just above Purfleet, and down Long Reach; it goes from angle to angle.

1196. Is that in any way different from what it was 15 years ago?—There is not so much current now as there was 15 years ago upon the shore owing to the quantity of mud, which prevents the opportunity of there being so much current, though it takes the same direction; the water cannot flow if there is mud to prevent it.

1197. Was the current there when the mud began to be deposited?—The current used to run there.

1198. And while the current was running the mud was deposited?—Yes it was to a large extent; the current used to run close to the causeway.

Re-examined by Mr. Morice.

1199. I take it that inshore in Erith Bay there is a large amount of mud?—Yes, a large amount of mud, so large that it is for anyone to see; it is not something that you can put out of sight.

1200. And you say there is not the same strength of tide in there now as there used to be?—No, it is impossible, simply because it is all filled up with mud; how can the water be there if it is filled up with mud?

1201. And at low-water mark is not there a good deal of slack water in the bay?—There is quite an eddy now. Where the Corinthian Yacht Club is, all those boats are continually doing a whirligig in this way (*describing the same*), simply because they are all blocked up with mud; there is no water as there used to be.

1202. How far does that extend, to Church Hole?—It runs from below Church Hole, to below Easton and Anderson's works.

1203. Where is that?—The lower part of Erith; all along in front of Erith. *Mr. M. Hind.* 4 Aug. 1882.

1204. You told my learned friend that you had spoken of the southern factories only; those are the only ones you know?—Yes.

1205. And with regard to this particular cesspool smell, it is open for my learned friend to go and smell it himself?—Yes, and then he would be convinced.

Examined by the Commission.

1206. (*Mr. Abernethy.*) When the wind is blowing from the north-east you smell it?—We do, and with a light wind much more than when it blows hard; with a light wind, and when it is foggy weather or not a very bright atmosphere.

1207. (*Dr. Williamson.*) Has that causeway, in your opinion, anything to do with the mud that is collected upon the side of the river; you say that there is more mud deposited of late years, and the causeway has been lengthened also?—That is the very reason for lengthening it, that the mud grew up so much that they could not approach.

1208. You are perhaps not sufficiently acquainted with the river to know much about the matter, but is not the causeway like a breakwater?—Not at all; part of it is upon piles.

1209. (*Chairman.*) What is the length of that part of it?—There would be only about 10 or 12 feet of piling in the middle.

1210. The rest is solid?—Yes.

1211. (*Dr. Williamson.*) And the new part which has been lengthened, is that solid?—That is upon small piles. It is timber or boards run out. It in fact almost settles upon the mud.

1212. (*Chairman.*) Did you rightly understand the question that was put to you by Dr. Williamson as to whether the causeway itself had been the cause of the accumulation of mud to any extent?—Not at all, it has nothing to do with it; the mud is on one side of the causeway as well as the other, but more upon the upper side, which is nearer the outfall. As regards it being a breakwater or anything that prevents the mud washing underneath, I say it is not; there is any amount of deposit 300 yards from the causeway before you come to it, all around the wharves and the piers where there is nothing to prevent it washing away, but still they are obliged to keep gangs of men for the purpose of washing and flushing it into the stream.

1213. (*Dr. Stevenson.*) You spoke of a change in the smell of the mud in the river; is that change in the kind or in the amount of the smell in your opinion?—It is a different sort of smell altogether from what it was when the sewer was opened.

1214. When did it begin to change its character?—It is a matter of degrees; I could not say that it was so much stronger one year than another, but it has been continually getting stronger; last year it was not so strong perhaps because there was a great deal of rain, and this year it has been cooler, and there has been plenty of fresh water and rain.

1215. (*Chairman.*) You are prepared to tell us that there has been a change both in quantity and in quality, in short?—I am. I have been used to boating for very many years, being almost always upon the river in my leisure time, particularly so before the outfall was opened.

The witness withdrew.

Mr. William Cobb called in, examined by Mr. Morice.

1216. What are you?—I am the oldest fisherman there is upon the River Thames now at this present time. *Mr. W. Cobb.*

1217. I think you live at East Greenwich?—I do.

1218. And you have been engaged in fishing upon the river since you were a boy?—Yes, for 60 years; I am 75 years of age now.

1219. Up to about 20 years ago now what was the best fishing ground in the river?—Erith Reach was the principal fishing ground.

1220. What fish did you catch there?—Eels, flounders, whitebait, and sometimes a salmon.

1221. (*Chairman.*) When you say "Erith Reach "was the best," do you mean for Erith people or the best along the Thames?—The best along the Thames.

1222. Of course we can understand it was the most convenient for Erith people, but would you say it was the best fishing ground along that part of the Thames?—It was.

1223. (*Mr. Morice.*) You used to fish the river in different parts?—Yes, from Greenwich to Gravesend.

1224. What part of the river around Erith was the part where you fished?—Erith Bight.

1225. Between what parts of the river?—Between Woolwich and Greenhithe.

1226. What part was the best for fish in the river where you used to fish?—It was all parts of the river; it was not always alike; it varied according to the season. I have caught whitebait off there; I have caught flounders, eels, and shads and all kinds of fish there according to the season; sometimes we have gone to Greenhithe and Halfway Reach, where the sewers are now.

1227. Whereabouts between the places you have already mentioned were the best places for fishing?—That would be according to the season and according to the water.

1228. But you have caught them in Erith Bight?—Yes, the most fish that ever we caught of all kinds was between Erith and Purfleet; that is in Erith Bight, upon the south side.

1229. When did that state of things begin to alter?

(*Mr. Bidder objects to the question as leading.*)

1230. (*Mr. Morice.*) Has that state of things altered?—Very much so, because there is nothing to be caught; there is nothing at all.

1231. When did you begin to find that you could not catch fish there?—About a week after the sewer had been opened, then the fish was a swimming on the top, at least they came up atop, and the swell from the steamboats and one thing and another drove them on the shore, and I could catch them with a basket, because they were all dead. I am a hooker man, that is I fish with hooks and lines, and previously to fishing with hooks we used to catch fish for bait, we used to lay the lines with 1,000 hooks a yard apart up the river, according to the best of our judgment.

1232. Now you say after the outfalls were opened you began to find the fish lying dead; has that continued ever since?—It has continued so that at last we can catch nothing.

1233. Where have you to go to get your living?—It has driven us right away to sea; where we could get whitebait four years ago, which we could do at Greenhithe, we have had to go to Grays, and from Grays to Gravesend, and we are now at Southend and Sheerness, and there is none to be caught, that is, whitebait, as to flounders and eels, there are none to be caught in the river at all.

1234. (*Dr. Williamson.*) Where is there any whitebait?—There is none this side of Gravesend now.

1235. (*Mr. Morice.*) You were going to tell the Commission something about the mode of catching

*Mr. W. Cobb.*
4 Aug. 1882.

bait?—We would catch whitebait and eels in the night, that was for a bait, and we laid the hooks, a thousand hooks, a yard apart upon a string, and we laid that upon the bottom, but now the bottom is in such a filthy state that we should lose lines, hooks, and all; at least I do not say we should lose the lines, but the hooks would be so overlaid with filth that it would break the snoods that the hooks are attached to.

1236. Have you found any difference in getting your nets up as compared with what it used to be?—We could not get them clean if we were to put them in.

1237. Why?—Because they would be corroded with all manner of filth.

1238. How long has that been the case?—Ever since the outfall first opened, it may be 16 or it may be 18 years. I never took that notice.

1239. You have been driven all away, have you not?—Yes, we have been driven further down all of us river fishermen, and I am the oldest.

1240. Did the water use to be drank?—I have known ships take water out of the River Thames at Deptford and Blackwall too, and not only that, but at Erith I have tipped my kettle over and boiled the water and drank it, clear beautiful water, at breakfast and tea, and now I should not like to drink a glassfull; I do not think I should live long if I did.

1241. How is it different now?—I do not know what to call it, it stinks enought to poison you.

1242. What colour is it?—All manner of colours. I cannot tell you what colour, it varies according to high water or low water; it is a different colour according to what way the stream is running. As to the bottom of the river, I could put in my pole and it would stand upright in it, and when I pick it up again and look at the end of it (*exhibiting disgust*).

1243. I understand from you that you consider there is a lot of filthy stuff at the bottom?—I do not know what it is, but it is something that smells very strong.

1244. What does it smell like?—Worse than any closet.

1245. Do you know the causeway at Erith. Well, I walked up and down it some thousands of times I was going to say, and I do not know that I should be much wrong, off Erith Gut, that is the middle between Jenningtree Point and Erith; we used to fish 14 or 15 boats, catching flounders and shads at times, and land at Erith, the beautiful causeway there (I suppose it is since the opening of these sewers) is so corroded that they have been obliged to build the causeway out further and further, and to build another one atop of it, and it is so washed up coming round the point by the tide inside that there is no passage at all, and so they keep on building it and building it till they will build it as high as this place for all I know. I know there is 12 feet clear settlings at the end of the causeway, and it may be more for all I know.

1246. Twelve feet clear settlings of what?—Of all kind of mud.

1247. You know Church Hole opposite the church?—I know it.

1248. Is there much mud in that bay?—There is a great deal of mud now, but it was a hard bottom, a hard gravel bottom. I have laid my hooks and lines there many hundreds of times and caught many thousands of fish.

1249. That is just above what is called the Gut?—That is Erith Gut where there was a good depth of water.

1250. Is there anything like gravel and hard bottom there now?—There is none to be seen whatever.

1251. What is there to be seen instead?—A black filthy stuff, mud. I do not know what to call it, it is all covered altogether.

1252. Has there been a greater amount of it within the last few years?—Yes, it keeps coming up every day there.

1253. When you say comes, does it remain there or does it come and go away again?—No, it never moves, it never can go away when it once settles upon the shore.

1254. Does it get more and more every day?—It gets more and more every day.

1255. (*Chairman.*) Do you not see any difference after there has been a deal of fresh in the river?—The thaw of the ice will make a little difference, it may wash a little of it into the deep water off the shore.

1256. Would not a considerable fresh from the upper part touch it?—No, it would not reach it at the time.

1257. (*Mr. Morice.*) Do you know the mud in the Medway?—Yes, well, I have been travelling in that way 11 years.

1258. Was the mud up near Erith anything like the mud in the Medway?—Equally the same, and nice mud it used to be.

1259. It used to be you say, when was it the same?—I will say 30 years back.

1260. What was the colour of that mud?—It was a bright mud, full of worms, food for fish, it was full of little red worms which I had to use upon the hooks, that was all a nice harbour for fish.

1261. Are there any worms in this part at Erith now?—No, there are no worms or anything else; you will see nothing but a black filthy mud, I do not know what else to call it.

1262. Is there any smell from that mud?—Oh, dear me, I should very much like some of you gentlemen to come down and let me put a staff down and examine it yourselves. I should like to take you down in my boat.

1263. Do you catch any shrimps there now?—No, nothing at all. I have my boats to work now in the Lower Hope, that is the nearest we can come up the river to catch shrimps at the present time.

1264. When did you have to go to the Lower Hope for shrimps?—The last two years, we did get them at Gravesend previously to that.

1265. Do you remember catching eels in the Thames?—Some thousands or hundreds of thousands. I have caught them as high as Woolwich, eels caught with whitebait as a bait, laying the hooks upon the bottom, and hauled them in by the hundred at a haul of all sizes. We have gone to Barking and we have tried all manner of places till we found out the best spot.

1266. Where have you caught them lately?—I have my gear all lying by, they are no use at all to me now. The last time I tried was at Greenhithe, I hauled nothing. I did haul a good many rope yarns and other things I could not describe.

1267. When was that?—About a month back.

1268. And you caught nothing?—I do not know that I shall ever get the stain out of the lines any more.

1269. Do you know what the eel boats coming up the river as far as Erith did?—I remember when the Dutch eel men used to lay out off Erith and they were towed up gradually upon the neap tide to market; now the same persons are obliged to go to Holy Haven and lie off there in the sweetness of the water to keep their cargo of fish alive.

1270. (*Chairman.*) Where is Holy Haven?—About seven miles below Gravesend upon the Essex side.

1271. Near Canvey Island?—Yes, and now they send them up in boxes. They sweep them out of the wells at Holy Haven and place them in large boxes and bring them up to London; they get them towed up as quick as they can astern of anything.

1272. (*Mr. Morice.*) What is the reason of that, do you know?—Because they could not bring them through the sewage water.

1273. *Mr. Bidder* objects to the evidence as not within the witness's knowledge?—I have had hundreds of eels, and I have had to take them out at Gravesend and spread them all over the boat to keep then alive, but when those got up to London I could put them in the Thames water again, but I must not put them in sewage water, as they would turn up directly; if there were two or three left in the well their heads would be about as big as two or three heads, and they would be

all manner of colours, they would be no good whatever.

1274. Would you tell us exactly where you take them up, and where you put them in again?—At Gravesend we take them out when we are coming to market. When we get about the middle of the pool, then we should put them into the water again; they like the London water, it is sweeter.

1275. Have you ever tried putting eels into water since the outfall opened?—I have. The way to kill an eel is to take some of the sewage water that is coming up and throw a live one in and he will lie straight directly, it will kill him quicker than cutting him up in pieces; when they once have a taste of it it is all up.

1276. You know the set of the tide and the course of it pretty well down the river?—I do.

1277. Can you tell us this; if sewage is put in at Crossness at high water where will it get to in the course of the ebb; take a spring ebb tide?—Providing you put a buoy and let it drive, I should say it is all dependent upon the spring tides and the dead tides.

1278. Take spring tides?—I should say Northfleet Hope or Gravesend, I would say it would drive to Gravesend. I have driven there in my boat without touching her or rather without touching the shore, I should say.

1279. It would then meet the flood and come up upon the flood; how far do you think it would drive up upon a flood tide?—Not quite so far as it would upon the ebb tide. If it was upon a spring tide I would say Erith, I do not think it would come much higher than Erith.

1280. Take an ordinary tide?—I would say Erith; it would not come back further than that. But when the sewerage comes out upon the flood tide, and of course it comes out swifter upon a flood tide, it will come up to Greenwich.

1281. (*Chairman.*) But we are told that the sewerage is not let out upon the flood tide, it is let out upon the first of the ebb?—It comes out within two hours of high water till they get a block, you have the flood tide making, and they let it run from the mouth of the tunnel till they get a block.

1282. You are speaking from your own knowledge, are you?—Yes, I am speaking of what I have seen myself.

1283. (*Mr. Morice.*) What do you mean by saying that it was let out upon the flood until there was a block?—When the water comes up as high as the mouth of the sewer then it is shut down and they do not work any longer, and directly they get a sufficient vacancy afterwards upon the ebb tide it rushes out again.

1284. Have you noticed it often within your own knowledge coming out before high water?—Yes, because we are frequently up and down almost ev day; I have been travelling up and down constantly, but not lately, because I have got too old for it now.

1285. But you have noticed it?—I have noticed it daily because I have been towed up astern of steam ships.

1286. And you have noticed it in the way you have told us?—Yes, I have.

1287. Now just another question upon how far the sewage would get. Supposing a portion of the sewage is let out, say four hours after high water, how far would that get?—It would not get far.

1288. How far would it reach?—About Purfleet.

1289. And then meeting the flood how far do you think that portion would get up the river?—Up to Woolwich.

1290. Is there any under current at all in the river when the ebb is making?—Yes, both ebb and flood, of course there is, but not half so much current as there is at the surface.

1291. Is there any backwater in the bays on the way down?—Yes, what we call eddy tides.

1292. Would there be any sort of young tide making up when the ebb tide is making down?—Yes, round the points.

1293. (*Mr. Bidder.*) Under the lee of the points?—Yes, but that does not interfere with the current of the tide, it is only a little portion from the shore.

1294. (*Mr. Morice.*) Do you know whether there is any current below the surface a little before the end of the ebb?—But that does not make any difference to the eddy near the points, anything that is drifting upon the top of the current and going round the point. The top current will turn it round, the underneath current does not interfere with that.

1295. You know what is called the saltings?—Yes, I do.

1296. Do you know whether there has been a great amount of mud deposited which is caused by the saltings?—Not at all. Saltings is a hard substance with wild grass on it, and clay and mud. I have known it to be in big lumps, as big as the table, and what have they done with it; they have repaired the banks with it.

1297. How have they repaired the banks with it?—They have put down planks and the navvies have put it in barrows, because they could cut it like cheese, and they repaired the banks with it. Having piled it up upon the banks they then put the stones against it, and it forms a hard substance.

1298. Therefore, as regards any mud which is deposited upon the banks, do you consider that that is caused by the saltings at all?—No, the saltings are nothing to do with it.

1299. Have you ever lost an anchor in the middle of the stream?—No, but I have been after an anchor, because I am a bit of an under-water man myself. I have been in there up near the sewer.

1300. Have you done that lately?—This last winter.

1301. Do you find any difference in the difficulty you have in regaining it?—I never got it at all, it went into the next world.

1302. To what do you attribute that?—I could not find it because it was all buried.

1303. In what way?—It was buried in the lower part of the river.

1304. (*Mr. Bidder.*) I cannot stand that; you did not find it, and therefore you do not know where it was.

1305. (*Witness.*) No, that was so, but still it was buried.

1306. (*Mr. Morice.*) Did you have greater difficulty in searching for it?

(*Mr. Bidder objected to the question.*)

1307–8. (*Mr. Morice.*) From the search that you made did you find that there was any difference in the mud in the bottom of the river from what it used to be?—We could not get the sweep along. We used to have a sweep line to sweep the bottom first, and if we got hold of it put a chain round it and heave it up; but now we could not get the sweep along because it sunk into the stuff at the bottom, thick and thin; it it was as thick as my arm when it came up.

Cross-examined by Mr. Bidder.

1309. Where did this happen?—In Halfway Reach.

1310. Now apparently you have had a considerable experience of fishing in the river?—I have; I have been 60 years at it.

1311. And did I understand that you were fishing for eels last month off Greenhithe?—We had a try, but caught nothing; we laid a few lines at Greenhithe.

1312. In the way of business?—Yes.

1313. You went there because you thought you would have a chance of getting something?—Yes.

1314. So it was worth while trying?—We thought so.

1315. Nothing had happened up to that time to prevent your trying?—No.

1316. You did not catch any?—Not one.

1317. Has it happened to you before in the course of your 60 years' experience to go and try and not catch any?—No, I do not say it ever happened like that because we always catch a few; 1,000 hooks will not let everything go.

*Mr. W. Cobb*
4 Aug. 1882.

1318. You never did such a thing before as trying to fish and catching nothing?—No.

1319. Not from your youngest day?—No.

1320. You have been more fortunate than I have; now you find your best chance of fish where there is a clear gravelly bottom, not where there is mud?—That depends upon what fish you are going to catch, and what time of year it is.

1321. As a rule for flounders and things of that kind?—For flounders a hard bottom, but for eels we like a softish ground.

1322. But you do not find eels where there is a great accumulation of mud do you?—Not such a great deal, else it would bury the hooks and bait and all.

1323. So that wherever you have a great accumulation of Thames bad mud there it is no use fishing for eels or flounders?—No.

1324. And I suppose it is the same thing with the whitebait?—Whitebait swims always on the surface, within a foot of the surface.

1325. Did you use to catch whitebait at Greenhithe?—We used to catch whitebait at Greenhithe and Grays; that was the last catching which I have seen, but I have caught more off Greenwich than I have anywhere.

1326. But I understand you to say that you used to catch whitebait off Greenhithe two years ago?—Yes.

1327. Are you still in the whitebait line?—Yes, I serve Messrs. Crosse and Blackwell, in Soho Square, with hundredweights of whitebait.

1328. Where do you catch them now, at Grays?—At Southend and Sheerness, and sometimes at Queenboro, that is close to.

1329. You have noticed the factories in the river which have grown up since you knew it first?—No, I do not think I have.

1330. Have you never noticed some works upon the river not smelling quite like your staff you know, but still not the most pleasant smell in the world?—I have not seen much of it running down.

1331. Have you not noticed much smell from the factories?—Yes, I have smelt them, but not anything running from them into the River Thames.

1332. Have you never noticed anything in the way of stuff running in from the factories?—I have not.

1333. Have you never noticed any scum from the factories floating upon the surface of the river?—No, none that was of any consequence, none that would hurt us.

1334. What was the stuff that you saw that was not of any consequence?—What we call the skimmage of the tide between high water and low water wherever it pitches, it is what we call the scum froth.

1335. You say it comes from the factories?—No, I do not say it comes from the factories.

1336. What does it look like, gas tar?—No, I should not say that.

1337. What does it look like?—It has an oily look.

1338. Have you ever seen fish turn up in it?—No, I do not know that I have, because it may go ashore and not come back again; we have not seen it the second day.

1339. Have you ever complained of things they have put in from the factories, and grumbled at them?—No.

1340. Have you never grumbled at all?—No, not as far as I can remember.

1341. Have you never noticed anything flowing in from the factories?—No.

1342. What were the fish you saw turn up upon the top of the water and die?—Shrimps, whitebait, eels, flounders and all kinds of fish.

1343. When was this?—About a week or a fortnight after the sewerage opened.

1344. Whereabouts did you see them?—I saw them at high water; goodness knows where they went to afterwards.

1345. But whereabouts did you see them?—In Halfway Reach.

1346. Were you alone or was anybody with you?—I had an apprentice with me.

1347. Was it on one occasion or upon more than one occasion?—I have seen them for a week or a fortnight afterwards keep gradually turning up from various reaches.

1348. Always in the Halfway Reach?—No, not always in Halfway Reach, because I have not been there every day.

1349. Where else have you seen them?—I have seen them as low as Greenhithe.

1350. Have you seen them of late years turning up in that way?—No, because there has been none to turn up.

1351. Stop a minute; you went fishing last month?—Yes, but there was not many to turn up, not this side of Greenhithe.

1352. When you say that there is not now a good place for fishing opposite Erith Reach, when was the last time you fished there?—I forget the time, because it is so long ago since I was there.

1353. Who asked you to come here and give evidence?—A gentleman who comes from Greenwich, I believe; I do not know his name.

1354. Did you have a meeting about this a week ago?—He asked me if I would collect as many fishermen as I could together, and I did so.

1355. Did you have a meeting at a public-house?—We did.

1356. What was the name of the place?—The "Golden Anchor."

1357. Was that the anchor you lost?—No.

1358. One you often hanker after, I dare say?—No doubt.

1359. How many of you were there there?—About a dozen of us.

1360. Who were there?—I do not know the gentleman's name, but he is here.

1361. Did he make a speech?—He asked us to collect the fishermen, and he asked me in particular, as I was the oldest fisherman there, to collect the fishermen together to see what we knew about it.

1362. After that I hope he behaved handsomely to you?—We had several pots of half and half.

1363. After having had these pots of half and half did he address you on the subject?—Yes.

1864. He told you what he wanted you to do, to find fault with the sewage?—Yes.

1365. Did he ask you how far you could help him?—Yes, he did so.

1366. He asked you if you could say the fish had gone out of the reach?—Yes, he did.

1367. He asked you if you could say that you had seen the sewage run down the Reach?—Yes.

1368. And kill all the fish?—Yes.

1369. You were all ready by the end of the meeting to come and give evidence for him?—We were quite ready.

1370. And parted very good friends?—I hope so.

1371. By the bye you said you have seen the sewage coming out upon the flood?—Yes, of course I have 20 or 100 times.

1372. At what time of the tide have you seen the sewage coming out upon the flood?—It has never left off at all from the ebb tide till they were compelled.

1373. The whole flood?—No, from the ebb tide, when they have sufficient room to begin on the ebb, they never left off till the flood tide stopped them, that is until it came against the mouth of the sewer, it was continually running.

1374. All through the flood?—As far as they could till about two hours before high water.

1375. (*Chairman.*) You mean to say they were discharging the whole of the ebb and the whole of the flood, except two hours before high water?—They could not commence upon the high water but when they had sufficient room, and so keep on gradually going.

1376. How early upon the ebb have you seen the sewage discharged, how soon after high water?—That is depending upon the flow of the tide. Sometimes a tide will flow 24 feet and sometimes 18 feet.

1377. What is the earliest you have seen after high water?—It might be 2½ hours.

1378. And you say they discharge the whole of the rest of the ebb?—Yes.

1379. And how much of the flood?—Till the tide had flowed up to the same mark as they began at.

1380. But I would ask how many hours would that be?—I do not know about the hours, we go by the tide.

1381. Would it flow till half flood?—Yes, that is about it.

1382. Are we to understand from you that you have seen the sewage flowing from half ebb to half flood?—Yes.

1383. (*Mr. Bidder.*) Until, as I understand you to say, the tide has so risen that it blocks the sewage back?—Yes, that is quite right.

1384. You mean they cannot let it flow out after it has risen to a certain height?—Yes.

1385. You mean to tell the Commission that that is a regular thing which happens every day?—Every day.

1386. And you have seen it hundreds of times?—I have.

1387. And you would say that as much sewage flows out upon the flood as upon the ebb?—Yes.

1388. Would you say more?—No, I do not say that.

1389. Have you many opportunities of seeing that?—Yes, I am continually, or I used to be out upon the river.

1390. You say there would be as much upon the flood as upon the ebb, or in fact rather more?—Yes.

1391. You have seen that this year daily?—Yes, I have.

1392. At both the outfalls?—Yes.

1393. Both Barking and Crossness?—Yes.

1394. The mud I think you tell us is quite a different colour in the river from what it used to be?—Yes to be sure it is.

1395. Used it to be a kind of a clear yellowy white, like sand?—It used to be mud with a worm in it, the red worm which is found in pure good mud, and the fish used to feed upon it.

1396. There are no worms in it now, are there?—No.

1397. Now what colour used it to be?—A kind of a brownish colour.

1398. Something like the wooden table just in front of you?—No, not that colour.

1399. This colour (*exhibiting whitey brown*)?—Yes, that was about the colour.

1400. Wherever you got it, whether from the bottom or the sides, or anywhere?—Yes.

1401. Not shiny at all?—No.

1402. Not greasy at all?—No.

1403. But rather sandy?—Yes.

1404. It would not stick to an anchor or a rope?—No.

1405. If you put your staff in it would not stick to it?—No.

1406. And it was quite sweet?—Yes.

1407. And now it is quite different?—Yes, it is 6 or 8 feet thick now.

1408. It is changed from the day when they opened the outfalls?—Yes, it is.

1409. The worms have all disappeared?—Yes.

1410. From that time?—Yes.

Re-examined by Mr. Morice.

1411. In fact there was, as you said just now, in former times a hard gravelly bottom?—Yes.

1412. Now there is nothing of the kind?—Now there is nothing of the kind.

1413. Now when this gentleman saw you at the "Golden Anchor," he took down what you had to say, did he not?—Yes, he did.

1414. Is this scum of the tide you told us about where the tide line is, between the tide and the slack water, or whereabouts is it?—That is caused by the point where the eddy tide runs; it comes out of the stream, and I consider it is partly purifying itself from the water which caused it to drift about.

1415. You tell us you cannot get fish where there is a lot of mud, would that depend upon what kind of mud it was.

(*Mr. Michael objected to the question.*)

1416. (*Mr. Morice.*) You say there are no worms in the mud now, and the mud is different from what it used to be?—It is quite different.

1417. Now with regard to the small amount of refuse which you say used to come from the factories, has that had any influence upon the fish in your opinion?—No, I should not say so, we did not find it so.

The witness withdrew.

---

# FOURTH DAY.

## Wednesday, 15th November 1882.

PRESENT:

The Right Honourable LORD BRAMWELL, F.R.S., in the Chair.

| | |
|---|---|
| Sir P. Benson Maxwell. | François de Chaumont, Esq., M.D., F.R.S. |
| Sir John Coode, Mem. Inst. C.E. | Thomas Stevenson, Esq., M.D. |
| Colonel C. B. Ewart, C.B., R.E. | James Abernethy, Esq., F.R.S.E., Mem. Inst. C.E. |
| Professor A. W. Williamson, F.R.S. | W. Pole, Esq., F.R.S., *Secretary.* |

Mr. Edwin Savery called in, and examined by Mr. Morice.

1418. I think you are the examining officer of the Customs at Erith?—I am.

1419. How long have you been at Erith?—About nine years.

1420. Has your duty taken you about the river in that locality?—I am daily on the water.

1421. What has been the state of the river during the time you have been there?—On some occasions it has been very bad, particularly in warm weather. Last year, when we had that very hot weather on two or three occasions, it was unbearable on the water. The moment that we got on to the pier my two men, who serve under me generally, used to say, "We know where we are, sir." We got the Thames aroma immediately we came off the village, but when we went afloat it was that bad on some occasions that, had it continued, I think it would have been almost impossible to have remained and done our duty. But if I may be allowed to observe, rather unfortunately for those who wish to do away with the sewage, the seasons for the last five or six years have been very much in favour of those who wish to continue the present state of things; we have had wind and rain and so on, and the result has been that we have not suffered as we did some years ago from the hot weather.

1422. Where do you find this smell worst?—When I am in Half-way Reach. The sewage comes out quite black.

*Mr. E. Savery.*

15 Nov. 1882.

1423. Can you notice the sewage in the river at all?—Unmistakably. You can see the line of demarcation so to speak, where the sewage runs and where the clear water runs. The water is hardly ever clear now, only sometimes a little after low water.

1424. How long have you known the river?—Nearly 40 years.

1425. Do you remember before the outfalls were made?—I do. When I was boarding foreign vessels coming from Gravesend, when I was in a subordinate position, when we got to Erith or even as high as Blackwall, the water was so clear that we used to drink it. Small vessels bound to sea did not go to the expense they go to now and have the water for which they had to pay, but they almost invariably dipped the river. It was the practice to dip at about half an hour before the flood, because then it is found that it meets the in-coming tide. It is driven back and you get the water fresher about half an hour after the flood than you do at any other period. They invariably took it to sea and drank it, and I have often drunk it.

1426. Do you know whether there has been any drinking of the water of recent years?—I do not think that anyone would be so unwise as to attempt it at present, and I am not aware of anyone attempting to drink it at present. It would not be drinkable.

1427. (*Chairman.*) Did the water ferment at all, not in the technical or chemical sense, but was there any perturbation in it?—There is great perturbation in it, but it appeared to me to be from air bubbles.

1428. Was that so when you used to drink it in the ship?—Not the slightest; nothing of the sort; it was almost like, in fact quite like, spring water.

1429. I have heard it said that even higher up the river, in the Pool, they took water out of the river and drank it; but there was a notion that it used to be what people call fermented?—There is a saying with the crews and captains of vessels (and it is a common notion, but I should think the correctness of it is doubtful,) that water should undergo one fermentation; that it is not good after you have gone to sea until it has undergone a change; but I should think that is open to very grave doubt.

1430. (*Mr. Morice.*) Do you know what is the state of the river above the outfalls now?—My duties do not take me above the outfalls, but only just at the top of the Reach where the outfall is.

1431. (*Chairman.*) But I suppose you must have noticed the water when the tide has been so low that the sewage which has been let out has gone beyond where you are?—I notice that from Erith and a little below Erith, and up to the outfall and a little below the outfall, we get that black dreadful sewage along the banks; and I have recently on some occasions gone and lifted some with a scull, or directed some of my men to do so, and it seemed to me to be pure black sewage. But I do not find that in Long Reach, or at Greenhithe, or at Grays; so that it would appear to me that there are some causes which are different below Erith. Why should it not accumulate, for instance, at the point off Purfleet and at Purfleet? There is no accumulation of this sewage there that I can see; but I found an enormous accumulation along the outfall right up that reach to the point at the top of Erith Reach and right away down Erith Reach. I noticed it more particularly when I knew that I had to come to give evidence before your Lordship, and I can see nothing of that sewage deposited on the banks below Purfleet.

1432. At very low tide the water at Gravesend is drinkable, is it not?—I should not like to drink it.

1433. It would be drinkable at Purfleet at very low tide, would it not?—I should imagine not.

1434. I mean but for the sewage?—We used to drink it, as I said.

1435. As low as Purfleet?—Yes, they used to dip it at Blackwall.

1436. But would it be drinkable lower down?—You are speaking with reference to its being brackish, I presume?

1437. Yes?—They would not dip it much below Purfleet, perhaps, because then you get it contaminated by brackish water.

1438. (*Mr. Morice.*) In the water in Erith Bight are there eddies?—There are; and I might observe that within the last few years just above Erith the vessels now, about two hours after ebb tide swing up as though it were flood tide, which is a thing that I never noticed in my nine years experience until these last three or four years. Some cause or other, which I should think must be the silting up of the river, causes those eddies, so that the vessels positively swing up. I used to have a difficulty in pulling up in the morning against the ebb but this sewage has assisted me in my duties, because we get a flood tide up. I have to visit the small vessels,—barges from Rochester and Faversham, and those places,—and just abreast of the outlet they bring up for the tide. It is a good shelter; being to some extent in a bight, they are out of the way of the steamers coming down; and I notice that within the last two or three years they have had to anchor a considerable distance out, and I have inquired of some of them why they do so. "Oh," they say, "we "cannot anchor where we used to, we should be "aground and in all sorts of difficulties;" and they all say that they are obliged to anchor at least 50 yards further out into the centre of the stream than they did a few years ago; and if that continues the River Thames will of course in course of time cease to be the River Thames.

1439. On the south shore above Erith do you know whether there are any deposits of mud?—Very large deposits, they do say 15 feet; but I notice that where the steamboats used to go in at certain times of the tide without difficulty, now they stir up the sewage and they get in with great difficulty.

1440. And continuing up the bight, past the Church Hole, has there been an increase of those banks during the last few years?—A great many feet I should say from my experience and observation. I have had no means of measuring; but from what I could see, that is so.

1441. Will you tell the Commission what those banks consist of?—I have tested them so far as the scull which we use will go down, and it appears to me to be solid black sewage. It is said by some that it is the breaking down of the banks, but I imagine that if it were the breaking down of the banks it would not smell as it does, because we have not only looked at it but we have smelt it, and it does not smell like the breaking down of the bank.

1442. Have you noticed it at low water?—I have.

1443. At low water on a hot day does it smell?—At low water on a hot day it smells dreadfully.

1444. Do you know the Causeway at Erith?—Yes.

1445. Do you know whether any alterations have been made in that causeway in recent years?—I understand that there have been two alterations, lengthening it something like 90 feet in consequence of the accumulation of the sewage, which some people say is the banks of the river, but I never saw the banks of the river like it for colour and smell.

1446. Will you tell the Commission how the sewage lies by the Causeway?—It lies, as it were, in heaps and piles, and it is unquestionably accumulating. It is black and smelling.

1447. Do you remember whether any fish used to to be caught in this part about Erith or in Half-way Reach?—Fish have been caught as long as I can remember up to within the last five or six years. When I was doing different duty to what I am now I used to board eel-scoots, and we used to come up to Erith, the water was as clear as crystal and the fish lived, and there was no complaint. I will not say since the sewage has been poured out at the outlet because it took place before that; but there is this about it, that the sewage which was so much annoyance to Westminster and to the noble lords and members of Parliament, that they could not sit in their chamber, they have relieved themselves of, and

have been kind enough to send down to Erith, and I am afraid that we at Erith have very much suffered. The eel-scoots had to leave Erith something like 18 or 20 years ago, but we can scarcely give the outfall credit or discredit for that, because so far as my recollection serves me, I think the outfalls have only existed about 16 or 17 years. They had to leave before the outfall was made. I attribute that to the state of the river.

1448. (*Chairman.*) The water had not got purified before it reached Erith?—Exactly.

1449. According to you the fish were poisoned then, and it is only a different mode of poisoning that is going on now?—Exactly so; but they should have taken it lower down.

1450. (*Mr. Bidder.*) You have told us about these eel-boats; do you know where the eel-boats stop now?—At Thames Haven. They went first to Greenhithe, but they found the water so impure at Greenhithe that they only remained there a year or two and then they went to Gravesend, and then the water was impure at Gravesend.

1451. (*Chairman.*) At what place down the river is the effect of the sewage imperceptible; you would not perceive it at Southend, I suppose?—I do not think you would.

1452. The volume of water is so great that it gets diffused?—That is so.

1453. How low down should you say that you are sensible of it?—My experience does not extend below Northfleet Hope; but I should say that at Northfleet Hope the sewage becomes so mixed with a large volume of water that you scarcely perceive it.

1454. Northfleet Hope is just above Gravesend, is it not?—Northfleet Hope is just above Gravesend.

1455. (*Mr. Morice.*) Then you would not think that there is much in Sea Reach?—I should say not, as far as I can judge.

1456. You were saying that these Dutch eel-boats have been driven down to Holy Haven, where they remain now?—Not merely the Dutch eel-boats, but all other fishing vessels. I can remember when there was a fleet of 50 fishing vessels about Greenhithe and Erith. They were shrimpers more particularly; I think that the flounders that they used to catch there were driven away earlier; I suppose the shrimps will live longer in bad water. The shrimping continued longer.

1457. There were, you say, a great many boats that used to fish close by there?—Yes, for flounders.

1458. Do you remember how many years ago they went away?—I should think not more than six or seven years ago.

1459. Do you know how far they go down now to fish?—I think they have to go down into Sea Reach, so far as I know; but my observation is not below Northfleet Hope.

1460. Do you know any illness that has been occasioned by this sewage?—There are vessels boarded that I have to supervise, and the officers have had to apply to me to get them medicine in consequence of their having diarrhœa on board, which they assumed was from the state of the water.

1461. In what parts of the river have you noticed these deposits of sewage beyond the portion either just above or below Erith?—I have not noticed any deposit of sewage but a very short distance below Erith.

1462. And the principal part, therefore, is in Erith Bight?—Erith Bight seems to be the great receptacle and there is an enormous increase of it. There is no doubt to anyone observing, as I have done daily, that the increase there is enormous from some cause.

1463. Do you know anything about some mooring buoys that were put down by the ballast wharf at Erith?—Yes, I have seen them, and I have seen that they do not lie in such deep water as they did formerly, and vessels which used to lie in there would certainly ground now.

1464. You were mentioning just now that you tried the depth of this mud with your scull; will you tell the Commission how far it went down?—The scull is only 12 feet long and we pushed it down some 5 or 6 feet, and I have no doubt, that had it been longer we could have gone deeper; but so far as we could ascertain, it seemed all to be of the same character, black sewage-smelling material, not such as you would get from the banks of the Thames.

Cross-examined by Mr. Bidder.

1465. I will ask you to be as definite as you can about one or two things. The first thing that you mentioned was that on certain occasions in hot weather the river smelt offensively; would you mind pointing out on the map at what part of the river you would experience that offensive smell?—I think I might say from Erith up to the top of Half-way Reach more particularly. I might say from half way down Erith Reach to the top of Half-way Reach.

1466. Above Erith?—No, below Erith.

1467. Now, perhaps you will tell me when?—The worst that I have smelt was last July, when we had that very hot weather. It was only for a day or two, until the hot weather ceased, but had the hot weather continued I will not say how bad it would have been.

1468. That is not so very long ago. Where did you smell it last July?—Off Erith.

1469. Was it very powerful?—Very.

1470. Have you ever experienced any offensive smell from any of the factories on either side of the river there?—I have done so from the atmosphere, but it did not appear to me to be from the water. You can tell generally whether a smell comes up from the water or whether it blows over your head. For instance, we get that smell in our houses at Erith; we do not get the smell of the Thames. All these smells from the factories we are favoured with in our dwelling-houses.

1471. But not the smell of the Thames?—No; because whenever you get the wind in a certain direction you get the smell of the glueworks and the paraffin-works. You can always tell the different smells according as the wind blows; but you do not get so much of the smell of the sewage on the land.

1472. You recognise the different smells?—Unfortunately I do; and so would you if you were there, I think.

1473. More or less savoury?—Very unsavoury.

1474. You also suggest to the Commission that there are very considerable accumulations, as I understand, which you say are accumulations of sewage, more especially in Erith Bight; am I right in that?—You are.

1475. And am I right in taking it as the result of your evidence that the only place where you recognise or suggest accumulations of sewage is in Erith Bight?—You are not quite correct there. I think I said in Half-way Reach as well.

1476. Do you mean opposite the Crossness Reservoir?—Just below that.

1477. On the south side?—On the south side.

1478. Those are the two places and the only places that you know?—To my knowledge.

1479. Let us have that definitely. On the south side in Half-way Reach, opposite and a little below the Crossness Outfall; and, secondly, in Erith Bight?—Yes.

1480. Have you taken any measures at different times to ascertain whether the mud in Erith Bight has been increasing?—It is, from observation. You cannot well make a mistake; you do not want to measure. You pass daily and you can see that a bank springs up like a little island; you know that it is there.

1481. How long is it since you began to perceive these accumulations in Erith Bight?—About four or five years ago they became perceptible.

1482. You could not perceive them before they became perceptible, you know?—Just so.

1483. Your business being on the river, to your knowledge, within recent years, have the Conservators of the Thames been carrying out considerable dredging

*Mr. E. Savery.*

15 Nov. 1882.

operations at that part of the river on the north side?—They have been continually.

1484. On the side of the river opposite to Erith Bight?—Yes, very considerably. They have removed several thousands of tons.

1485. They have removed a large projecting shoal known as Erith Rands, have they not?—Yes.

1486. And they have very greatly improved the channel of the river on that side?—It is improved, but I saw a vessel aground there not long ago. No one thought she would be aground.

1487. There is room for something more?—There is room for something more.

1488. Of course that has greatly deepened the water on the north side of the river?—It must have done so.

1489. And it has driven the stream more to that side?—It would do so undoubtedly.

1490. Are you surprised that that should have the result of making an eddy on the opposite side?—It might have that effect to some extent, but I do not think that it would have the effect of creating sewage.

1491. That I concede; but it might have the effect of accumulating good honest mud?—I grant you that, but not sewage.

1492. That takes me to my next point. Upon what ground do you say that the material of these banks is sewage and not river mud?—I have not analyzed it, although I might do that; but I have sufficient perception to know the difference between sewage and the sand off a bank. The delivery of thousands of tons of what you may call river mud happens o come under my notice. The whole of the cement t at is made on the River Thames is made from river mud and river deposit up at White's, at Greenhithe. They manufacture cement: in fact they are the largest cement manufacturers in the world, and all the river mud is brought from Rochester to Greenhithe which would be of the same character as this silting up would be if it were from the breaking down of the banks of the river. But I do not see anything at all corresponding with this river mud, thousands of tons of which are landed there every year.

1493. Leaving the cement mud at Greenhithe, what are the particular characteristics in this Erith mud that lead you to say that in your judgment it is sewage?—Its smell, colour, and general appearance.

1494. What colour is it?—Black.

1495. Turning brown on exposure?—No, remaining black as far as my experience goes. You can see it for yourself there; it is black on the surface at all times.

1496. Is it within your knowledge that the town of Erith discharges its sewage by open sewers at that very point into the river?—It is, and it is also, if I may so say, within my knowledge that they did so before this enormous silting took place.

1497. But, however, it is the fact?—It is the fact.

1498. How many sewers discharge in that Erith Bight?—I am only aware of one. I might mention that a great part of the sewage of Erith is put into cesspools and not into sewers. I have reason to believe that it is only the leading part of the place that is drained by sewerage.

1499. I will not discuss with you what portion of the town sewage it is, but it is the fact?—Still I think it is only fair to know what the whole of a large place like Erith does with its sewage.

1500. Still it is the fact that one or more sewers discharge into that Erith Bight; one to your knowledge?—Yes.

1501. Is that close to the Causeway?—No.

1502. Which is the one that you know?—The one that I know is below the pier. I do not think there is any other.

1503. Are you aware that there is also a sewer discharging at the Causeway?—I am not aware. I have never noticed it.

Re-examined by Mr. Morice.

1504. Do you know whether or not there are a large number of cesspools in the parish of Erith?—I always understood so; not from actual knowledge. I have some property there.

1505. Is not this sewer that you have been asked about, below Erith, near the ironworks?—It is only about a foot in diameter. The quantity that that could discharge would be a mere bagatelle to what we see.

1506. With regard to the mud that you have been talking about, you say that you know it from the smell and colour; does it leave any stain?—It stains the water.

1507. Does it stain anything that is put into it?—I have never tried that. The water that is about it is all black.

1508. And remains black?—And remains black.

1509. The factories that you have been asked about above Erith, you say have different smells which you can distinguish?—Yes.

1510. Have you any doubt about the smells from them being different from this sewage smell.

1510*a*. (*Chairman.*) It is manifest that there are other smells and that the witness can distinguish amongst them.

1511. (*Mr. Morice to the witness.*) I understand you to say that this sewage deposit is all from the south side of Half-way Reach down to Erith?—That is so; below Erith down towards the point. I do not notice it in Long Reach, but that might be due in some measure to the shoot of the tide through Long Reach. In Long Reach there is not much position for it to accumulate, but I do not see that it accumulates at Greenhithe where it might accumulate, because Greenhithe is quite in a bight and Long Reach is a straight reach.

Examined by the Commission.

1512. (*Chairman.*) Can you give us any further information which you think will assist us in this inquiry that we have to make?—I am of opinion that if this state of things goes on for any length of time, eventually you will lose the River Thames; that it must naturally silt up the river.

1513. I do not know that we can take your opinion as to what the consequences will be, because you are not an expert; but can you give us any information as to anything that you know or have seen or smelt, in addition to what you have already told us?—No, not in addition to that. I have been asked whether I thought the factories had the effect of killing the fish, and I have said, Why do they not kill the fish in the Tyne? You have more factories along the banks of the Tyne, and they do not kill the fish there. Fish is abundant in the Tyne, showing that it is the enormous amount of sewage that kills the fish and not the chemical works.

1514. Are fish abundant in the Tyne?—So I am told.

1515. You do not ever hear Newcastle salmon cried now, do you, though you used to?—Perhaps not.

1516. (*Professor Williamson.*) There is one point on which, perhaps, you will be so good as to give some further particulars to the Commission. You said, I think, that the deposit which is collected from the bed of the river for the purpose of making cement is always of one kind?—Yes, it is of a lightish colour.

1517. Do you mean by that that every deposit which you could collect is of that kind, or that they only collect that which is of a particular sort; are there not some banks of sand and others which have more of clay in their nature; are there not varieties in the composition and properties of the material which you find deposited in the Thames?—Quite so; but in all my experience of the deposits, I have never seen any deposit that looks and smells like that which you get at Erith.

1518. With regard to this particular deposit at Erith, did you say that your oar sinks into it, and that it is softer than the other?—Quite so. The other

deposit goes on gradually, and the clay accumulates and it eventually gets turned into stone, but that of course is the work of ages. But this sewage would be soft, and if you had a probe long enough you could probe the 15 feet which they say is the depth of it.

1519. And there is no other deposit so soft?—There is no other deposit so soft, it is saturated so thoroughly with water. But in the case of the clay the water does not seem to saturate it so much.

The witness withdrew.

Mr. Joseph Hathaway called in and examined by Mr. Morice.

1520. Do you live at East Greenwich?—Yes.

1521. How long have you been on the river Thames?—Fifty years.

1522. What have you been doing?—Fishing, and in the Metropolitan Thames Police.

1523. How long have you known the river for fishing?—I have known it for fishing for 50 years.

1524. During this time what was about the best part of the river for fishing?—The best part of the river at this time of the year, in November, is from Blackwall, and Erith, and Greenhithe.

1525. Which do you consider the best reach in the river?—Erith Reach.

1526. What fish could you catch there?—Flounders, eels, smelts, shrimps, and shad at times.

1527. Were there many fishing boats that used to fish there?—About 25 or 30; sometimes more and sometimes less.

1528. What is the state of things now with regard to fishing?—There are no fish to be caught from Greenwich. You can get no fish this side of Gravesend; nothing nearer than the Lower Hope, which is below Gravesend.

1529. (*Chairman.*) Between Greenwich and Gravesend there are no fish?—Between Greenwich and Gravesend there are no fish.

1530. (*Mr. Morice.*) When did you begin to find the fish gone away?—I should think the first of the fish decreasing in this river is about 16 years ago, from 1865 to 1866.

1531. What had the state of the river been before that time?—The water in this river was in a beautiful state; you could dip a pot overboard and drink the water.

1532. What part could you take the water from?—From any part you liked, in any reach you felt disposed; but now it is poison.

1533. Do you know whether it was commonly the case that the water was taken for drinking purposes?—I have done it myself, and I have seen ships, when they have been going away to Greenland, take the water in at Deptford, and water the ships from there.

1534. (*Chairman.*) How high up the river did your experience extend?—Up as far as Deptford.

1535. You used to fish up as far as Deptford?—Yes, and catch bushels, tons, of flounders, and eels, and whitebait, and shrimps. We used to catch whitebait off the "Trafalgar" and the "Ship" taverns, in front of the premises, and take them ashore as they wanted them; and now there is nothing to be seen.

1536. (*Sir J. Coode.*) What is the furthest point up the river at which you can catch whitebait?—The furthest point at which you can catch whitebait is the Lower Hope, Southend, Sheerness, and Queenborough.

1537. (*Mr. Morice.*) How long ago is it since you could catch whitebait a little higher up, say in Erith Reach or in Halfway Reach?—No whitebait, to my knowledge, have been caught in Erith Reach or Halfway Reach for, I should say, 14 years at least; it may be a little over.

1538. In fishing below Gravesend can you bring the fish up the river to market?—You must take them out of the water. The water is good below Gravesend, but as soon as you come above Gravesend with flounders and eels you have to take them out of the water until you get past the sewage water if you want to bring them to Billingsgate alive.

1539. What do you mean by taking them out of the water?—You have got a net on an iron hook and you sweep the fish out from the well and place them on the boat's deck, on the boat's flooring, and they will live there when they have not this poisonous water, until you get above where the sewage water reaches, and then you can put them into the well again.

1540. You mean that they will live better on the deck of the boat than in this poisonous water, until you get past it?—They will do so.

1541. (*Sir J. Coode.*) Do you, as a matter of practice, take them out of the water and then put them in again?—Yes, you can do that; or you can take out the flounders or eels, and they will live until you get above Gravesend, if the weather is cool, until you get to Billingsgate Market.

1542. But do you put them in again when you get above what you consider the sewage point?—Yes.

1543. (*Mr. Abernethy.*) How far up the river do you consider the sewage point?—Up above Greenwich.

1544. (*Chairman.*) What are you now, a fisherman?—I am not following that pursuit now. I did follow it; but I was an inspector in the Thames Division of Police. I have been up and down the river at all times—night and day and all.

1545. And what are you now?—I am going up with barges now with Mr. Henley, of North Woolwich.

1546. You said in answer to a previous question that you now take the fish out of the water; you mean that the fishermen do so?—I understood the question to be, "Do they now?" and not to have reference to myself.

1547. (*Mr. Morice.*) Does the time at which you put the fish back again into the wells depend upon the time of the tide?—It will be on the flood-tide when you put them in.

1548. (*Chairman.*) You say that you do not do it yourself; but I suppose you know that the fishermen do it?—Yes.

1549. Does the well communicate with the exterior water?—Yes, there are holes in the boat's bottom which allow the water to come from the river into the well.

1550. And do they return the fish into the well?—Yes.

1551. At what point do they do that?—They do that up above Greenwich.

1552. (*Mr. Morice.*) And then, on the flood-tide, the water is good enough to admit of their putting them back again?—After you get above Greenwich it is.

1553. Can you tell us the state of the river banks from, say, Barking?—Yes.

1554. Has there been any deposit of mud there in recent years?—At Barking do you mean?

1555. Or on the banks at either side?—Yes, there is now, and it has greatly increased.

1556. Whereabouts is it chiefly deposited?—It is deposited against the northern outfall down at Barking Creek, and from Crossness in Half-way Reach and Erith. The Causeway at Erith, where we used to make our boats fast to a ring, has been heightened three or four times, and now it will have to be heightened again. At Jenningtree Point, where 20 or 30 barges used to get sand, they cannot get sand at all, or when they do get it they have to rake the black, stinking mud on it.

1557. You know the Causeway at Erith?—I do. We used to make our boats fast to a ring there.

1558. Can you do so now?—No; it is overflowing with mud. There are five or six feet of mud there now—nasty, stinking, black sewer stuff. You cannot call it mud; it is not mud.

1559. How far did it go from the bank?—It is from the bank right away down to low water.

1560. Do you know the fact of the Causeway being

*Mr. J. Hathaway.*

15 Nov. 1882.

lengthened?—The Causeway has been lengthened, and it has been raised three or four times.

1561. Did the water about the part you have been mentioning, Half-way Reach and Erith Reach, have any effect upon your nets?—When the water was clear in the river our fishing nets would last about twice as long as they would last now, for the water now completely rots them, and you cannot get them clean; but when you take them out and wash them they stink so that you can hardly bear them in the boat.

1562. (*Professor Williamson.*) I thought you did not fish any more now?—We did do so until such time as the sewage water came down, and then it drove all the fish away, and you could not get the nets clean, and they would rot in one third the time that they would before.

1563. (*Chairman.*) When did you leave off fishing yourself?—I left off fishing myself in 1851; but I have been on the water side ever since. I have been in the Thames Police going up and down.

1564. Have you ever experienced this inconvenience in the case of the nets that you used?—Not when I was fishing. I am speaking of the nets of other people. I have seen them myself.

1565. (*Mr. Morice.*) You have been about the water side ever since?—Yes, and on it. I was Inspector of the Thames Police.

1566. (*Sir J. Coode.*) When you were Inspector, what was the extent of your district up and down the river?—From Blackwall to Deptford Creek, and down as far as I felt disposed to go. I have been down to Greenhithe or Gravesend.

1567. (*Mr. Morice.*) I believe as Inspector of Thames Police it was your duty to be afloat?—It was, night and day.

1568. Therefore you have seen and smelt a good deal of the river in consequence?—I have.

Cross-examined by Mr. Bidder.

1569. As far as fishing yourself goes, you have had nothing to do with it for 30 years?—No, but I have been up and down and alongside of the boats when they have been fishing at Greenwich and at Erith and at Greenhithe.

1570. I understand that there are no fish to catch above Gravesend?—There are not now.

1571. Then I presume there is not anybody fishing for them?—No; they cannot get any; nothing nearer than the Lower Hope.

1572. How long is it since fishing has been given up above Greenhithe, as far as your observation goes?—I should think about 14 years.

1573. So that practically I may say that there has been no putting of nets into the river above Greenhithe since the sewers were opened?—Yes, they have put in the nets, but with no effect; they have not been able to catch any fish. They found that as the water was so bad in the river they had to go further down for them.

1574. With reference to the deposit you have spoken of at Erith by the Causeway, do you know when that Causeway was built?—No, I do not. Do you mean the original one?

1575. It was lengthened some few years ago, was it not?—Yes, it has been lengthened and raised; but I did not take the dates of course.

1576. When was it lengthened?—That I cannot speak to.

1577. I need not ask you whether you know about the dredging operations. I suppose you have no particular information as to that.

1578. (*Chairman.*) You have had that from one witness, and I think your own observation is a tolerably plain one, that those operations would have a tendency to create an eddy.

1579. (*Mr. Bidder to the witness.*) You say that fish cannot be brought up in the wells of boats; are you aware that the Dutch eel-boats come up to the Pool with eels in their wells now?—They do not. The Dutch eel-scoots used to lie at one time at Erith, but now they are obliged to lie at Holy Haven, and they are brought up in trunks.

1580. Will you undertake to tell the Commission that it is not the fact that Dutch eel-boats come up to the Pool with live eels in their wells?—To the best of my knowledge they do not. They come up to sell the eels which they bring from Holland over here, but not in the wells.

1581. You reside at Greenwich; were you one of the gentlemen who met at the "Golden Anchor"?—I was at the "Golden Anchor" some time ago.

1582. A gentleman came down and a certain number of pots of porter were distributed amongst the fishermen. Do you know Mr. Cobb, who was a witness here?—I do.

1583. Were you one of the gentlemen invited by him to come to the "Golden Anchor"?—I was at the "Golden Anchor."

1584. Where there was a gentleman who gave you all pots of porter?—Not many pots of porter.

1585. And who asked you to say what you could say against the sewage?—Not against it. He asked me, "Are you a fisherman?" and I said, "Yes, I have "been on the water for 50 years." He says, "I want "you to state what you know about the fishing and "what you have seen: speak truly and honestly on "both sides."

1586. I daresay your account will not differ from Mr. Cobb's. He had several pots of half-and-half. He was asked, "Did he tell you he wanted you to find "fault with the sewage?—(*A.*) Yes. (*Q.*) Did he "ask you how far you could help him?—(*A.*) Yes, "he did so. (*Q.*) He asked you if you could say the "fish had gone out of the Reach?—(*A.*) Yes he did. "(*Q.*) He asked you if you could say that you had "seen the sewage run down the Reach?—(*A.*) Yes. "(*Q.*) And kill all the fish?—(*A.*) Yes." Is that about what took place?—Mr. Cobb was there before I was, so I cannot say.

1587. He was commissioned to invite the rest of you?—No, he was not.

1588. I see he added that you all parted very good friends?—Yes, we parted very good friends.

Examined by the Commission.

1589. (*Sir B. Maxwell.*) You were a fisherman down to 1851?—I was a fisherman down to 1851.

1590. Then you went into the Thames Police?—Yes.

1591. How long were you in the Thames Police?—I was in the Thames Police for 21 years. I left in 1871.

1592. Then from 1871 down to the present time how have you been employed?—I was on Mr. Henley's Telegraph Works at North Woolwich, going backwards and forwards on the barges.

1593. Does that keep you on the river daily—Yes, and at night as well.

1594. (*Chairman.*) Where do you live now?—At No. 44, Marlborough Street, East Greenwich.

1595. This condition of the Thames of which you complain does not trouble you where you dwell?—No.

1596. In what part of the Thames do you work now?—From North Woolwich up to the East India Docks, the West India Docks, and Milwall Dock with barges.

1597. Do you smell the sewage?—Yes.

1598. How high up the river do you detect it?—Up as far as Blackwall Reach, and sometimes in Greenwich Reach.

1599. In what states of the tide do you detect it so high up as that?—On the spring tides, when the tides are running heavy, then it comes further up the river; but in our police galley, when they were letting it out in Half-way Reach, and likewise at the northern outfall, and especially in the summer time, there used to come such a faint, nasty, stinking smell that you could hardly bear it, and it turned you sick.

1600. That was below North Woolwich?—Yes, that was at the northern outfall.

1601. It is not much trouble to you now, because it is only occasionally that you smell it?—Yes, only occasionally. It was our duty in the police galleys, if we saw offensive matter, to summon the parties.

1602. It is only on spring tides, as I understand, that you smell it now when you are at work?—Only at spring tides, and then we smell it at Blackwall and Greenwich Reach.

*Mr. J. Hathaway.*

15 Nov. 1882.

The witness withdrew.

Mr. James William Farthing called in and examined by Mr. Morice.

*Mr. J. W. Farthing.*

1603. You live at East Greenwich?—Yes.

1604. How long have you known the river Thames?—62 years; and I have been on the water 62 years.

1605. Do you remember the sewage outfalls being opened?—I reckon it is from 16 to 17 years ago.

1606. What are you?—I am a Greenwich waterman.

1607. What was the state of the river before the outfalls were opened?—Very good; ships of all kinds used to get their water for drinking there, to take to sea.

1608. At what part did they get it?—Between Limehouse and Woolwich; but mostly about Greenwich, if they could get there.

1609. (*Chairman.*) I do not notice that there is any cross-examination as to that?

1610. (*Mr. Bidder.*) I did intend to ask one question about it.

1611. (*Chairman.*) There is no doubt that at one time the Thames water was drinkable at London Bridge, because there were waterworks there.

1612. (*Mr. Bidder.*) I have always understood, as your Lordship said, that it fermented, and, after that, it was considered the finest water to take to sea.

1613. (*Chairman.*) I suppose it may be admitted that that is not the case now?

1614. (*Mr. Bidder.*) That is not the case now.

1615. (*Witness.*) It is not.

1616. (*Chairman*) He might give us, if he can, the date when that ceased to be the case.

1617. (*Mr. Bidder.*) I am told that ships are not now in the habit of filling their water casks from the river.

1618. (*Witness.*) No; it would be poison.

1619. (*Mr. Morice.*) When did the ships, to your knowledge, cease taking in water from the river?—I should say about 14 years ago. I recollect the fishing smacks belonging to Greenwich about 14 years ago, that is about the last time that they used the water for taking to sea, because I worked for a gentleman of the name of Mr. Roberts, who was a smack owner, and I was employed by him over 22 years, and I used to take his fish from Gravesend to Billingsgate Market.

1620. Then 14 years ago you remember their taking water for drinking purposes?—It might be 15; I cannot exactly say.

1621. Since that time you do not know that they have done so?—No; the water has been getting worse and worse since that.

1622. During the last 8 or 10 years has it been getting very much worse?—Every year it gets worse. The eel scoots used to lie just above Erith, in Erith Gut, in the Bight, and there eels would live well. In a couple of years, after the sewers commenced, they had to shift to Gravesend, and the eels would not live there; and then they had to go down to Holy Haven and lie in Holy Haven harbour with their eels.

1623. Are eels easily killed; are they hard fish to kill?—They do not like bad water. They will live longer out of water than they will in bad water.

1624. You say that the river has got worse; in what way has it got worse?—On account of the sewers.

1625. How do you find that the river has got worse?—I will tell you. I worked for these smacks over 22 years, and they used to bring their fish to Greenwich before they swept them out. And now the fish will not live at Gravesend; the water is not so good now at Gravesend as it used to be at Greenwich at that time 18 or 20 years ago.

1626. How were you employed on the river; did you have anything to do with this fish business?—Yes.

1627. What did you do?—The smacks used to go to the North Sea; and sometimes they would bring 50, 60, or 70 score of cod up to Gravesend and market a certain quantity away every day until they were out; and the last day the vessel would go home up to Greenwich with the fish in them, and they would live till they got to Greenwich. That was before the sewers commenced.

1628. What did you do in it?—I and my mate had a boat; it was always a two-handed job, and we used to take a certain quantity, such as 8, 10, or 12 score while the vessel was lying at Gravesend up to Billingsgate Market every day till the fish was gone, according to what the vessel had.

1629. Since the sewers were opened has this been altered?—They cannot come in the river at all; at least the fish will not live in the river at all. They will not live out of Sea Reach. In the Lower Hope they begin to turn up.

1630. Then do the boats stop with the fish at the Lower Hope?—They do not come up here now. They were forced to keep down there. They go to Harwich or anywhere according as the wind is, where they can fetch. They go into Lowestoft, Harwich, Grimsby, Yarmouth, anywhere according to the wind, and they send them up by rail.

1631. Have you left off fishing?—I am a waterman. At the first commencement I went to sea with my father when I was 15 years old, until I was old enough to be bound apprentice to the water; and I have been at work on the water now for 62 years since I was apprenticed.

1632. (*Sir B. Maxwell.*) Not as a fisherman?—No; as a waterman. In the first place before I used to work for these fishermen, I used to go up and down as pilot with shipping, with vessels of all kinds. That was before there was any steam.

1633. (*Mr. Morice.*) Being on the water, have you noticed anything with regard to your ropes in the water so far as their smelling is concerned?—Yes, I should say that if you came to let go an anchor it was like hauling up so much grease, and you would hardly make out whether the anchor was iron or a lump of muck.

1634. When the anchor came up, what was there on it?—A kind of slime, not mud, a mixture like; I cannot tell you what it was—a mixture of mud and slime more like grease than anything else.

1635. (*Chairman.*) That is the case now?—Yes.

1636. (*Mr. Morice.*) Was there any smell to it?—Beastly. All the way up and down along the south shore from the sewers right down below Erith, in rowing up, if you take and shove your scull in and stir it up you will find that it is a mixture of mud and slime.

1637. Do you know the whole of the river all the way down to Gravesend?—I should think I do.

1638. Have you noticed whether there have been any mud banks formed on either side of the river?—I think there is a deal less water than there used to be.

1639. Do you know whether there has been any mud at all formed on the way down the river?——

1640. (*Chairman.*) Is this the same mud bank in the Erith Bight?

1641. (*Mr. Morice.*) Partly, my Lord.

1642. (*Chairman.*) We have it conceded by the other side that that is attributed to another cause.

1643. (*Mr. Bidder.*) My learned friend is perhaps not aware, but your Lordship or some of the Commission will probably be aware, that that question was the subject of a preceding arbitration which was exhaustively gone into.

1644. (*Chairman.*) My impression of that inquiry was that the award was that there was as much water way as ever; but I do not think that they said that the banks were in the same place, did they?

*Mr. J. W. Farthing.*

15 Nov. 1882.

1645. (*Mr. Bidder.*) No, my Lord. Of course the Commission is in no way bound or concluded by the decision of that arbitration; but still it may save a little time if I tell you that the question there was this: that under one of the sections of the Metropolitan Board Acts the Conservators had a right to take the Metropolitan Board to arbitration if they believed that the sewers had in any way interfered with the bed of the river by causing silting up. They did accordingly make the charge against the Metropolitan Board that the results of their outfalls was to produce accumulations of matter. For that purpose it did not matter whether this was sewage matter or pure sand, but it was alleged that it was producing accumulations at different parts of the river. When we came before the arbitrators, they confined themselves ultimately to those that have been mentioned to-day, one at the Barking outfall, one off the Crossness outfall, another that you have not heard of on the north side, and the one in Erith Bight which they did not rest so much upon. They rather admitted that they must give that up. The result of it was that the whole of that arbitration was fought upon the one question whether these banks were caused by the sewage outfalls or not. That question the arbitrators determined in our favour; they determined that they were not.

1646. (*Mr. Morice.*) It was a question, then, of the navigation of the river, and not a question of the deposit of sewage, which is quite another matter.

1647. (*Mr. Abernethy.*) With all due deference to the learned counsel, I think what was proved was that the navigable channels had not been materially interfered with.

1648. (*Chairman.*) Supposing that the bank was not what you may call caused by the sewage, and that there would have been a bank without the sewage, still if it is a bank of sewage deposit it is obviously a matter that we must inquire into.

1649. (*Mr. Bidder.*) Of course that arbitration had nothing to do with the question, supposing that the bank was produced by causes other than sewage, what the components of the bank were.

1650. (*Chairman.*) This arose out of a question which I asked Mr. Morice, whether he was going to examine this witness as to the existence of a bank, which it is conceded does exist. But what it is made of is another question, and how it was constituted is another question.

1651. (*Mr. Morice to the witness.*) Do you know the south shore along Half-way Reach down to Erith?—I do.

1652. Do you know whether there is any deposit of mud along that shore from Half-way Reach down to Erith Bight?—Yes, from the half-way house point, that is Crossness, down to Erith.

1653. (*Mr. Bidder.*) It was an admitted fact on the arbitration that there was a very large accumulation of mud opposite our Crossness outfall. The question as to what caused it is another matter.

1654. (*Mr. Morice.*) I mean to go further than that. (*To the witness.*) Do you know whether there has been any increase in the last few years of the banks of mud along that shore?—Yes, a good deal.

1655. Can you tell the Commission of what it is formed?—It is a nasty greasy soil. I cannot tell what to call it; it is not regular mud as it used to be, it is more like grease.

1656. You remember the bank along that shore; what sort of bank used it to be, say, 20 or 30 years ago?—What they called the saltings.

1657. And now you say it is not mud, but a slimy substance.

(*Mr. Bidder handed to the Commission a copy of the Report and Determination of the Arbitrators in the case referred to.*)

1658. (*Chairman.*) Does it not come to this, that there is a greater draught of water and that vessels of greater tonnage can come up, but that the channel is to a certain extent narrowed by the formation of banks, so that the ships cannot make as long boards and tacks as they used to make; that the dredging by the Conservators has mainly occasioned the foundation of these banks, but that no doubt they are to some extent increased in size by the sewage.

1659. (*Mr. Bidder.*) I do not think they say that they are increased in size.

1660. (*Chairman.*) They are said to be "partly "from denudation of the river bed, partly from sewers "in districts outside the Metropolitan area, and partly "from sewers in the Metropolitan area. The pro- "portion contributed from this latter source is small "as compared with the total amount of suspended "matter in the whole volume of tidal water which "flows past the outfalls on every tide. Whilst, there- "fore, the sewage from the Metropolitan outfalls may "have contributed to their contents, the three banks "cannot be said, in the sense of the Act of 1870, to "have arisen from the flow of sewage at the outfalls; "and we are therefore of opinion that the Metro- "politan Board of Works should not be called on to "remove or contribute any portion of the expense of "removing the three banks, or any of them."

1661. (*Mr. Morice to the witness.*) Will you tell the Commission why you say that this soil is not mud?—It is not mud; you cannot call it mud.

1662. Why do you think it is not mud?—Because it is of a slimy nature.

1663. What colour is it?—All manner of colours, yellow and black.

1664. (*Mr. Bidder.*) I do not know whether I might suggest to my learned friend that we had in that case, and probably shall have again, a large body of scientific evidence. Surely the chemical constitution of this mud is not a question for this witness.

1665. (*Chairman.*) What can this witness tell us more than he knows, that the bank is there, and that in his judgment it is mainly made up of sewage matter?

1666. (*Mr. Morice.*) Quite so, my lord, I am not asking him any further than that, except that from his knowledge he knows that it is not ordinary mud.

1667. (*Witness.*) It is not what it used to be 20 years ago; and not only that, I know that in Half-way Reach where there used to be 15 or 16 feet of water there are not above 10 feet now.

Cross-examined by Mr. Bidder.

1668. I am not going to ask you about the mud, but about one other matter. You spoke about the condition of the river when you raised an anchor. How long is it since you were on the river working as a waterman?—62 years from the time I was first bound.

1669. Are you at work now as a waterman?—Yes.

1670. Every day on the river?—Not exactly every day. All that I do now is, I may say, Jack's last push; that is doing a little sculling; but I have had charge of craft of all descriptions.

1671. When were you last down at Erith?—About a month ago I went down with a vessel to Gravesend, but still I did not stop there, I went right by Erith.

1672. You have told the Commission a good deal about the condition of the water getting more unsuitable for drinking and for fish; is that what you refer to when you speak of the river getting worse?—Yes. In the summer you can hardly bear yourself, for the smell of the water at Greenwich at high-water time when you have two days warm and calm.

Examined by the Commission.

1673. (*Chairman.*) Where do you work now?—At Greenwich.

1674. Upwards or downwards, or across; are you a waterman for passengers?—Yes, now. Formerly I used to go up and down with shipping, but now the old people are no go. I do a little, what I can, in sculling. I take Mr. Yarrow's people backwards and forwards: he builds these torpedo boats. That is all I do now. I do not go much down now.

1675. You do not very often go to where the smell is?—I work for a man who is now the master and owner of a vessel, and who was one of my former master's apprentices, and I always go up and down with him, but that is the only time I go down the river now.

1676. You have no particular interest in this matter; this smell does not trouble you much?—No, only at high water in summer time, and then it stinks awful.

1677. Even up at Greenwich?—Even up at Greenwich.

1678. At what state of the tides; spring or neap?—Sometimes at spring tides, if the weather is warm. I will tell you the reason of that. About 20 fathoms from the south shore where the outfalls are, it is all the heavy tide on the ebb, about the last quarter ebb. The sewer still keeps pumping this stuff out. That does not go down, it all comes out and settles. Then when the flood comes where that eddy is, the flood runs hard and away it goes up with the flood; it does not go down after the last quarter ebb; it does not go any further down, it comes out and settles. And then when the flood comes up that which remains, which has not settled, comes.

*Mr. J. W. Farthing.*

15 Nov. 1882.

The witness withdrew.

Mr. James Clarke called in and examined by Mr. Morice.

1679–80. I believe you were born at Erith?—Yes.

1681. And you are now a boot-maker?—Yes.

1682. And you have been a watchman at Price's Oil Works along the banks of the river?—Yes.

1683. How long do you remember the river?—I can remember the river from three years of age, and I am in my fifty-eighth year.

1684. That is over 50 years. Do you remember the state of the river before the outfalls were opened?—Yes; it was pure.

1685. You say the river was pure before the outfalls were opened?—Yes, before the outfalls were opened.

1686. After that, did you notice any alteration in the river?—Yes. The river has been filling up the whole time, and if it was not for the Thames Conservancy dredgings, no ships of any heavy draught of water would be able to come up.

1687. You say that it has been filling up; whereabouts has it been filling up?—In different parts of the channel, both north and south.

1688. Have you ever bathed in the river?—Yes.

1689. How long ago?—In my younger days, up till I was about 20 years of age.

1690. Have you bathed in it lately?—No, it is not fit to bathe in.

1691. Was there ever any sand or firm walking on the banks of the river near Erith, years ago?—Yes; when I was about 16, from that up to 20, in my bathing time, you could walk from the lower ballast wharf to Jenningtree Point on hard dry sand, but you cannot find any now.

1692. What is there now?—It is all a black slimy mud up to your middle.

1693. Do you know the Causeway at Erith?—Yes.

1694. Has there been any alteration made in that?—Yes.

1695. (*Chairman.*) Have we not had that over and over again? Is it not conceded and not cross examined to?—We may take that for granted.

1696. (*Mr Morice to the witness.*) How long were you at Price's Factory as watchman?—Over nine years.

*Mr. J. Clarke.*

1697. How long ago was that?—I went there in 1864, the year after the gunpowder explosion in the marshes.

1698. During that time did you notice anything unpleasant about the river?—Yes; I have noticed it many times, and have gone home ill in the morning after leaving duty.

1699. What did you notice that was unpleasant?—An unpleasantness comes off the river similar to decayed animal matter. I had been at Price's about three years when an accident happened to me. I fell overboard, and I was taken home from there very seriously ill, and a medical man now deceased told me——

(*Mr. Bidder objected to this evidence.*)

1700. (*Chairman.*) We could not take that.

1701. (*Mr. Morice to the witness.*) You were ill at any rate?—Yes.

1702. During the time you were at Price's you say the river was unpleasant. Was it so often?—I would say it was most unpleasant during the hottest part of the summer.

1703. (*Chairman.*) Did you fall into the water which you say is foul water?—Yes.

1704. Can you tell us what were your sensations. Did it have any unpleasant effect on you?—Yes; I went home in the morning, when going off duty ill, and I stopped at home for about three days through taking in a large quantity of water.

1705. You could not help swallowing some of it?—No; because I went under one barge and came up at the tail part of it.

1706. Then you felt the bad effects of swallowing the water?—Yes, certainly I did.

1707. Have you ever felt any ill effects from it since?—Not from the water, because I have never been in the water since, but I have from the smell being alongside of the river.

Cross-examined by Mr. Bidder.

1708. Where was it that you fell overboard; was it in the river itself?—At Mr. Price's works, alongside the wharf, near upon high water.

1709. Were you some time under water?—I went in at one end of the barge and came out at the other.

1710. Then you were in a very exhausted state when you came out?—Yes.

1711. I daresay you had swallowed a good deal of water?—Yes, I had.

1712. Were you conscious when they got you out?—I was conscious, and I came out and sat on the bank.

1713. And you felt very bad afterwards?—Yes.

1714. And you had two or three days at home?—Yes.

1715. What do they make at Price's Factory?—They are tar distillers, turpentine distillers, oil refiners, fat refiners. I do not think you could call them makers of any article; they are refiners and purifiers.

1716. Are there any unpleasant smells in connexion with the manufacture of those various things?—No, I cannot say that there are, without it is smoke, because there are enough fumes of acid about to kill anything.

1717. Have you ever heard of the people of Erith complaining of the abominable smells that came from Price's Factory?—Well, I have oftentimes seen it in print.

1718. It is a matter of constant complaint in Erith, is it not?—I do not know whether they put it in on purpose to injure the plant or no; but oftentimes when the wind is in the east it will carry the smell inland.

1719. But there have been not only a good many notices in print, but the inspectors have been sent down several times to Price's works, have they not?—I do not know.

1720. You were employed as a watchman at Price's?—Yes.

1721. Since that, what have you been doing?—I was laid up about 15 months attending hospitals, and after that I came home. I was apprenticed to the boot trade.

*Mr. J. Clarke.*

15 Nov. 1882.

1722. For the last 10 or 12 years you have been employed in boot making?—No, only about three and a half years.

1723. Who asked you to come here?—Mr. Frederick Parish wrote to me to come.

1724. (*Mr. Morice.*) He is instructing me on behalf of the Local Board.

1725. (*Mr. Bidder to the witness.*) Is it a fact within your knowledge, that at Price's Factory, the refuse from the factory runs into a ditch?—Yes; but I believe that now, at the present time, it runs into pits. There was only water when I was there.

1726. When you were there, did the refuse run into a ditch?—Yes.

1727. And did that ditch run into the Thames?—It came in communication, I believe, with what they call a sewer ditch.

1728. And so got into the Thames?—Yes.

1729. (*Dr. Stevenson.*) Where is Price's Factory? Just below Jenningtree Point, about 200 yards from Jenningtree Point on the south side.

Re-examined by Mr. Morice.

1730. Do you know whether there used to be any sea-weed just above Erith?—Yes; I have used it as manure, and other people too, largely.

1731. How many years ago would that be?—That would be in about 1859.

1732. Have you been able to get any in the last 10 or 15 years?—No, not in large quantities. I very much doubt whether you would get half a ton, from the Half-way house to Greenhithe.

1733. Can you tell the Commission why you have not been able to get it.

1734. (*Chairman.*) Does it grow there now?—No, not now; it is dwindling away.

1735. (*Chairman.*) I thought that this sewage was a great promoter of the growth of vegetable matter.

1736. (*Mr. Morice to the witness.*) With regard to the factory smells you say that they are quite distinct from the sewage smells?—Certainly they are.

The witness withdrew.

*Mr. J. Thorne.*

Mr. John Thorne called in, examined by Mr. Morice.

1737. You live at Greenwich?—Yes.

1738. Have you been engaged in fishing in the river there?—Yes.

1739. For how many years?—I have been engaged, along with Mr. Cobb, 10 years.

1740. What are you now?—A waterman.

1741. Where do you ply?—We do not ply at all; we go down the river looking after our living amongst the small craft and shipping.

1742. Do you remember the sewage outfalls being opened in the river?—Yes.

1743. What was the state of the river before that time?—The state of the river before that time was that the water was very good, all up and down the river.

1744. Did people drink it at all?—Yes, I have drunk it many times. Likewise we used to always fill the water at Barking for the smacks.

1745. Since the outfalls have been opened, has there been any difference in the state of the river?—A deal.

1746. In what way?—The water is very bad and very black and very stinking.

1747. Has that been so more particularly in the last few years?—It has been so more particularly ever since the outlets have been opened.

1748. You used to be fishing on the river up to how many years ago?—I have left off now about nine years.

1749. What fish used you to catch in the river?—I was down in the Lower Hope catching whitebait, shrimps, flounders, eels, and all sorts of fish.

1750. Before the outfall was opened what was the best part of the river for fishing?—Somewhere about Erith, at Erith Rands.

1751. (*Chairman.*) That was your fishing ground?—Yes.

1752. I thought you said that you went to the Lower Hope?—That is lately.

1753. Formerly you used to fish at Erith?—Yes, that was before the outlet.

1754. (*Mr. Morice.*) Used there to be many fishing boats at Erith?—Yes, lots.

1755. How many at a time?—There used to be, I cannot say exactly how many, but I should say from 30 to 40 boats standing off, shrimp catching, whitebaiting, and one thing and another. They caught fish of all sorts and any sort.

1756. Was it a good fishing ground?—Very good indeed.

1757. When did you have to leave that fishing ground?—They have had to leave that fishing ground now, I should say, about from 15 to 16 years, as near as I can guess.

1758. What did you have to leave it for?—On account of the outlets of the sewers.

1759. Where did you go to after you left it?—We went down fishing at Grays, and Greenhithe, and Gravesend, and the Lower Hope, and all round.

1760. What is the highest part of the river towards Erith where you fish now?—The highest part that I have been fishing in, in the latter end of my fishing, was Gravesend Reach.

1761. What did you catch there?—Shrimps, whitebait, flounders, eels, and all sorts of little fish.

1762. How long is it since you used to fish at Greenhithe?—When we were last standing at Greenhithe was about from 12 to 13 years ago, for the bait.

1763. When you catch the fish down at Gravesend can you bring them up the river?—We can bring them up to a certain place and then take them out and spread them all over the boat and row up to Billingsgate with them.

1764. When you take them out and spread them over the boat, what is that for?—To keep them alive. They would not live in the water.

1765. Why?—Because the water is so bad.

1766. When do you put them in again?—If you want to put them in again you can put them in at what we call the Dutch eel-scoot pier off the Custom House.

1767. What effect does it have upon the fish, supposing that you do not take them out when you get into this bad water?—It kills them all. They would not live in the water a minute.

1768. (*Chairman.*) They die at once, do they?—Yes.

1769. (*Mr. Morice.*) You find that it is better to take them out?—Yes.

1770. (*Chairman.*) Did it seem what one may call a sudden death, or did they struggle first and then die?—They died directly, as soon as ever they got into the water. When you come into Half-way Reach, if you put the fish overboard you would see that they died directly.

1771. (*Mr. Morice.*) But did they jump about or do anything of that kind?—No.

1772. (*Chairman.*) They do not struggle at all?—We do not leave any in the wells to struggle, because when we are in good water we take them out.

1773. (*Sir B. Maxwell.*) You say you take them out at a certain place; where do you take them out?—We take the fish out at Gravesend.

1774. (*Mr. Morice.*) Then you say that you can put them in again when you get up to the Custom House?—You can at times: it is all according to the water. We have put them in and they have lived at the Custom House.

1775. Is there any smell from this water in the river?—It is very bad indeed in hot weather.

1776. Does it have any effect upon your nets when you put them in?—There is nothing but slime in our nets, but they do not put any in now. It is no good putting any gear over at all for fishing in the river from Woolwich to Greenhithe.

1777. And you have given it up for that reason?—Yes.

1778. Is there any difference in the colour of the mud in the river, so far as you have seen, in the last few years?—A deal. It is not mud, it is more like slime than mud.

1779. What is the colour of it?—Black, very black indeed.

1780. Is there any difference between that and the water in the River Medway?—Yes, a deal.

1781. What is that like?—That is clear.

1782. Are the water in the River Thames and the mud different from what they used to be?—A deal different.

Cross-examined by Mr. Bidder.

1783. I understand you to say that before the outfalls the condition of the river was very good, both up and down?—Yes, both up and down.

1784. How far up; up to London Bridge?—The water was good up to London Bridge, and above that.

1785. There were no complaints of it?—There were no complaints of it. At one time the water was bad. I think that was about 1852 or 1853. We had a plague with the water then.

1786. There was nothing to speak of in the condition of the river?—Nothing like it is now.

1787. There was nothing really objectionable in its condition?—Nothing at all.

1788. You never heard of any complaints of the condition of the river before the main drainage works were made?—I never did in my life.

1789. You, I understand, have not been a fisherman for the last 9 or 10 years?—I have not.

1790. You do not know anything about the Dutch eel-boats?—I do; and I have fetched the eels up to London out of them.

1791. Do you know whether they bring up eels in their wells?—They do not. They sweep out at Holy Haven mostly, and then they run up or come by tugs.

1792. They never bring eels up in their wells?—No, I never knew them do so; not lately.

1793. Were you at the meeting at the "Golden Anchor," by-the-bye?—No.

Re-examined by Mr. Morice.

1794. You say that there was nothing to complain of in the river. Do you mean in the upper part at Greenwich or lower down the river?—Before the outfall was opened.

1795. What part of the river did you mean when you said that there was nothing to complain of?—Before the outfall was opened the water was good all over. We could drink the water at Gravesend when there had been heavy rain; but now you cannot drink any at all because it would poison you.

Examined by the Commission.

1796. (*Chairman.*) I suppose that at some part up the river what you call the bad effect of this sewage ends, does it not. Does it ever reach as far as Deptford?—No, it does not get up as far as Deptford. I never knew it get as far up as that.

1797. Is the water at Deptford now better or worse than or the same as it used to be some 20 years ago?—It is not fit to drink there now,

1798. Do you know why?—I do not know the reason why. There is no fish there either.

1799. That is not owing to this sewage?—I cannot say that that is owing to the sewage. I do not know.

1800. You said that the affect of the discharge of this sewage ceases at some point up the river?—It comes up to about what we call "Bugsby's Hole," and above.

1801. In parts of the Thames mud, at all events, there used to be red worms, used there not?—There was.

1802. And if you threw a stone on the mud they all disappeared, did they not?—No, I never saw them.

1803. Are there any of those red worms now anywhere?—There are none at all.

1804. Can you tell me any spot where there used to be mud, where they were?—Yes, in Erith Rands there used to be a deal of those red worms on the mud.

1805. What has become of them; are they all gone?—They are all killed, I suppose.

1806. Do you find them lower down the river still? No, I have never seen any at all lately.

1807. I mean as low down as Grays or Gravesend?—I never saw any at all lately anywhere.

1808. They are killed all the way down?—I do not know where they are gone to. I never see any down there at any time.

1809. (*Sir B. Maxwell.*) Until 10 or 11 years ago you used to be a fisherman?—Yes.

1810. Since then you have been a waterman?—Yes.

1811. Since you have been a waterman how far up the river do you come?—I come up to Billingsgate.

1812. Do you come above bridge at all?—No.

1813. You come as far as the Custom House or Billingsgate?—Yes.

1814. Do you come as often as once a month as far as Billingsgate?—Yes; once or twice a week sometimes.

1815. How low down the river do you go?—We go sometimes as far as the Nore and Southend.

1816. That is not often, is it; you say you generally go down to about Gravesend?—Below that.

1817. You live at Greenwich?—Yes.

1818. How far below Gravesend do you generally go?—It is all according to the weather. We cannot go in our boats down there if it is blowing very heavily.

1819. You pull a wherry, do you not?—Yes, a skiff.

1820. For carrying passengers?—No, I do not carry any passengers; I work for shipping.

1821. (*Chairman.*) What is called "waiting on ships"?—Yes; piloting these small craft up and down.

1822. (*Sir B. Maxwell.*) Do you ever go down as far as Chatham or Rochester?—I do not go down there now. I have been at Queenborough whitebait fishing.

1823. How long is it since you have been as far as Rochester?—It is a long while ago since I was up as far as Rochester.

1824. Have you been there for the last 10 years?—I have not been there for the last 20 years.

1825. Then you cannot tell us very much about the state of the Medway?—I cannot.

The witness withdrew.

Mr. Thomas Parkinson called in and examined by Mr. Morice.

1826. I believe you are a Trinity pilot and waterman?—Yes. I served my time to the water and I am a pilot. I have my license in my pocket. I have been on the river pretty well all my lifetime. I was about 10 years old when I first went on the river.

1827. You have been on the water all your life?—Pretty well.

1828. Do you remember the outfalls being made in the river?—I remember it before there were any outfalls at all.

*Mr. T. Parkinson.*

15 Nov. 1882.

1829. What was the state of the river before the outfalls were made?—The water was all good and the shores clean mud; but now it is all a yellow green, all sorts of colours. Where it was sand it is all muck, and where we had 15 and 16 feet of water in Half-way Reach, we have about 9 feet now.

1830. How long ago was that?—Before we had the outfalls. I am sure I cannot say for a year or two how long it is.

1831. And now you have only 9 feet?—About 9 feet now. No ships bring up on the south shore at all now; there is not water for them.

1832. What vessels used to bring up on the south shore?—Colliers; all coasting vessels.

1833. You say that the water was very good; do you know whether vessels used to fill in water?—Yes.

1834. In what part of the river did they fill in water?—As far down as Long Reach, I have known them fill it at low water.

1835. How long ago did they give that up?—A long time now.

1836. Could you say how many years?—I could not say. I never took that notice, but they have not done it for some years past. When I was apprenticed to my father we always drank the water out of the river.

1837. You do not drink it now?—No.

1838. Why not?—Because it is rank poison.

1839. (*Chairman.*) It has been admitted very explicitly that formerly vessels did get their water from the Thames. and that now they cannot do it.

1840. (*Witness.*) All the transports, all the Botany Bay ships filled their water when they lay at Woolwich, and took it in there for the convicts. They used to have a wooden pump over the side to pump the water into the casks or tanks or whatever they had.

1841. (*Chairman.*) Did they do that in the Pool?—No; the collier ships dipped their casks in the Pool.

1842. But the sewage does not reach up to there at all?—I do not know. I never heard of any ships taking in water there at all now.

1843. They used to take it in the Pool, but they do not take it now in the Pool?—They do not.

1844. That is not in consequence of this sewage, is it?—I suppose it must be through that.

1845. Does the sewage ever get up to the Pool?—I do not see why it should not.

1846. Do you see why it should?—I cannot see why it should not. We can go further on the flood than we can on the ebb.

1847. (*Mr. Morice.*) As you have been a pilot, you have had something to do with anchoring in the river have you not?—Yes.

1848. In getting the anchor up have you ever found any deposit of mud of any kind?—You find plenty of muck on it and on the chain too. You have to get a boat forward with a bass broom to wash the muck and dirt off the chain as it comes in, or else the deck would be smothered with it.

1849. You are obliged to have somebody forward in a boat in order to get the mud and dirt off the chain?—Yes; you have a hand in a boat with a broom, and as you heave the chain in they wash it off outside.

1850. You said there was muck upon it?—You cannot call it anything else; it is all sorts of muck.

1851. Is there any smell or stink about the muck that you get up on the anchor and chain?—Yes, I warrant you it smells.

1852. You say that it stinks?—As you heave the chain in, so this muck comes up.

1853. Is it ordinary mud, or what is it?—It is muck; it is not mud, and it smells fit to choke you.

1854. And you say that you have a boat with a hand in it in order to sweep it off before it comes up?—Yes.

1855. That is to prevent its coming on to the deck?—Yes, to keep it from coming in board.

1856. Has this been getting worse in the last few years?—I think it gets worse and worse every year. We find a good deal less water all the way down about Halfway Reach and Tripcock Reach and different places. Even from Blackwall Point, as you go down along there, you find that the mud is collecting, and dirt and muck is collecting there, where we used to have good water all along. Now there is hardly any water at all right away along down to Bugsby's Hole, Woolwich Reach, and Tripcock Reach, right away down Halfway Reach.

1857. (*Chairman.*) The first places that you named are above the outlets, are they not?—Decidedly so.

1858. But you say there is still a silting up there?—There is a silting up all along on the opposite shore on the north side in Woolwich Reach. It is growing up very much lately.

1859. (*Mr. Morice.*) That is above Halfway Reach and then down past Erith?—Yes; right down Long Reach.

1860. You know Erith Bight, I suppose, pretty well?—Yes.

1861. Will you tell us if there has been any alteration in the mud, or whatever it is, in Erith Bight in the last few years?—There used to be sand at Jenningtree Point where the barges used to get the sand. Now it is all covered with mud, or I do not say mud, but it is all muck.

1862. You know the sweep right round Erith Bight down to the Causeway?—Yes, certainly. They have raised that Causeway two or three times. The old Causeway is, I dare say, two or three feet down in the mud.

1863. What sort of stuff is that?—It is all soft muck. It is all different colours.

1864. In going up and down the river, have you noticed any smell from it?—Yes, and when we heave a ship's anchor up you can smell it; and if I am on board of a screw or towing up astern of a steamboat she will stir it up at low-water time, and it will smell fit to choke you.

1865. At what time of year is it the worst?—In the summer it is the worst, in the hot weather. It smells worse then than it does in the cold weather.

1866. Have you noticed, in going up and down the river, fishermen in different parts of the river?—Yes.

1867. When did you use to meet with them?—When I was master of a steamer, about 30 years ago. I was master of a boat called the "Swiftsure" when first the propellers came in. We were riding opposite where the "Trafalgar" is built now, and the fishermen used to come inside of us and put their nets over, and catch the whitebait and send them to London.

1868. And now you do not meet with them?—Lord a' mercy, there is not a tittlebat that would live there now. I have not seen one.

Cross-examined by Mr. Bidder.

1869. You say that the river smells, as I understand you, principally in the summer?—More so in the summer than in the winter.

1870. Can you point to any place where it principally smells?—Half-way Reach for one place. Even in Limehouse Reach you can smell it, and on board the Woolwich boats at low water.

1871. Principally at Halfway Reach?—Halfway Reach, Tripcock, Woolwich, and those places.

1872. Nobody can go up and down without smelling it?—No.

1873. (*Chairman.*) Do you say that Long Reach has silted up?—Long Reach, Erith Reach, and Halfway Reach.

1874. Long Reach is between Purfleet and Greenhithe, is it not?—Yes.

1875. That you say is silted up?—There is mud; it is very bad there in Long Reach.

1876. At low water what is the mud on deposit at the sides; is it the old mud that used to be there?—No, it is more like the colour of this table, a sort of brown.

1877. How far down the river does this style of mud or deposit go?—I have seen it in the lower part of Long Reach. In fact I have seen nearly as far down as the pier at Gravesend. No longer ago than last Sunday morning I was noticing the stuff that had settled there.

1878. Do not people bathe at Gravesend?—I have not seen anyone bathe there for a long time now.

1879. I thought there used to be machines there?—There used to be machines at Northfleet, but they have done away with them and there are none now.

1880. Do you smell it down there?—Yes, you can smell it there at times. In Long Reach you can smell it very strong.

1881. (*Sir B. Maxwell.*) Do I rightly understand you to say that Halfway Reach, which was formerly 15 feet deep, is now only 9 feet deep?—There are only 9 feet of water.

1882. At what part of the Reach is that?—In what they call the collier section from Halfway house down as far as Jenningtree Point.

1883. (*Chairman.*) Do you mean that vessels of the same burden that used to come up cannot come up?—They do come up, but they cannot ride in Halfway Reach. Their section is filled up. Where the colliers used to be sectioned, there is only 9 feet now.

1884. (*Mr. Bidder.*) It is the same thing, my Lord; it is a bank off Crossness.

1885. (*Chairman.*) I think you admitted that too.

1886. (*Mr. Bidder.*) There is not the slightest doubt that a bank has accumulated in recent years on the south side of Halfway Reach, and I dare say his figures are correct. That is the bank which was the subject of the previous arbitration.

1887. (*Chairman.*) But there is more water on the north side, is there not?—Yes, there is more water there. At Dagenham Dock there is good water; they have taken the shelf away.

The witness withdrew.

1888. (*Chairman.*) I do not know whether the Commission would think that we should see samples of this stuff?

1889. (*Mr. Balfour Browne.*) The City have samples which will be produced before you at the proper time, both of the water and of the mud or "muck," as the witness calls it.

1890. (*Mr. Morice.*) I have other witnesses to call, and one of my witnesses, Mr. Charles Beadel, offered to produce some of this very mud which has been taken from Erith Causeway.

1891. (*Chairman.*) One has had a great many cases where the question has been whether there was a right of way for example. A dozen witnesses have been called, and they say, "I always thought there "was a way, and I used it and I never was stopped," and so on. It is no use calling another dozen to the same effect; you may take it that in the neighbourhood there are twenty-four people who would say so; and then without saying that that proves the right of way, you say, "It is no use calling more witnesses to prove this." Then you wait and hear what the case is on the other side. May we not deal with this case in a somewhat similar way? There are many very respectable people who come with a strong impression, for which they give thsir reasons, that the sewage has contaminated the water, and has left a deposit and that the shore is offensive, as has been described to us. Is it any use calling another dozen witnesses to say the same thing? I would suggest that to the learned counsel, although I have not consulted my colleagues. Do not suppose that my suggestion is that the case is made out. All I say is that there are a great many people who believe the same thing that these witnesses have told us.

1892. (*Mr. Morice.*) I may tell your Lordship that I have a great number of witnesses who can speak to the facts which have been deposed to already and to other points bearing upon the same matter. They are of different classes; but I am quite willing to leave the matter in your Lordship's hands.

1893. (*Chairman.*) I dare say Mr. Bidder would admit that you could call twenty more witnesses who could state the same facts, and honestly believe them, as the witnesses have.

1894. (*Mr. Morice.*) I could call a great many more than twenty.

1895. (*Chairman.*) The more you could call the more fear I have of your not accepting my suggestion.

1896. (*Mr. Morice.*) I have already tendered to me proofs to the extent of between 200 and 300 witnesses, who will state the same thing.

1897. (*Chairman.*) That shows, I think, the reasonableness of my suggestion. There is a very large number of people who entertain the same opinions, and would give the same reasons for them as the respectable witnesses whom you have called before us. I dare say Mr. Bidder would admit that.

1898. (*Mr. Bidder.*) My Lord, I go further, because as I have indicated to your Lordship to a great extent, I admit the facts. For instance, about these banks in Halfway Reach and opposite the northern outfall, I admit the fact, because I admitted it in the previous arbitration. I have thrashed it out, and I know every turn and corner of it.

1899. (*Chairman.*) And that the water is no longer used by shipping, and that fish are no longer caught where they used to be caught?

1900. (*Mr. Bidder.*) Yes. Then as regards the smell, I do not admit all that these gentlemen say, but I admit that if you go into the neighbourhood of the outfall you smell a smell. Beyond that, it is a matter the Commission can judge for themselves.

1901. (*Chairman to Mr. Morice.*) You hear what Mr. Bidder says and perhaps you will think it over, although I do not say that if you have a very prominent, capable, intelligent, and knowing witness we should not be glad to hear him.

1902. (*Mr. Bidder.*) I indicate to-day that my learned friend may be put upon his guard, that as regards any special pollution about that causeway, Erith Bight, or any particular sewage presence there, I have very good reason to believe that Erith itself is the principal cause of the pollution.

1903. (*Chairman.*) You admit the bank, but you deny that you are the cause of it?

1904. (*Mr. Bidder.*) Quite so.

1905. (*Mr. Morice.*) My learned friend Mr. Bidder has cross-examined not only to-day but on previous occasions with regard to these Dutch eel-boats, and he has also given me an indication that he contests the point with regard to the pollution of the water, because he does not admit that part. My case here is not simply that the water has been deteriorated in the ordinary sense, and that the ships' crews do not drink it, but that there is a sewage pollution which is not only in the water but which also affects persons who have business connected with the water.

1906. (*Mr. Bidder.*) I am anxious to help the Commission to shorten the proceedings in any way I can, but I should be very sorry whilst doing that to lay myself open to its being said that I misled my learned friend as to what I admit. I admit most distinctly that fish are not caught in those parts of the river where they used to be caught, and that to some extent it is considered desirable to take them out of the wells when they come up to Billingsgate, although I have reason to know that it is not universal. But my learned friend must not suppose that in admitting that I am admitting a polluted state of the river.

1907. (*Chairman.*) It is admitted that the difference has taken place since, and, as it were, upon the opening of these outfalls?

15 Nov. 1882.

1908. (*Mr. Bidder.*) I am told, and so far as I know, I think it had begun before, but no doubt to a great extent it has increased since.

1909. (*Chairman.*) That is a very proper admission, and we can draw our own conclusion from it, that there has been a considerable increase since the opening of the outfalls.

1910. (*Mr. Bidder.*) What I want my learned friend to understand very distinctly and pointedly is, that I draw a distinction between admitting the disappearance of the fish and admitting what my learned friend seems to think that necessarily indicates, viz., the pollution of the water, because I shall have a great deal to say about that.

1911. (*Mr. Browne.*) In reference to what my learned friend Mr. Bidder has said, his admission is with a view, as I understand it, of shortening the case, and of making it unnecessary for my learned friend to call certain witnesses whom he proposed to bring before you. That is a matter which affects my learned friend, but which also affects myself and my learned friends who appear for the Corporation. If my learned friend Mr. Beaumont Morice does not prove the facts that he has wished to substantiate, it will be necessary for us to call certain evidence before you. One part of the evidence that we proposed to bring was to show that it is impossible for any fish to live at all in the water between the outfalls and Waterloo Bridge and below the outfalls too. Of course I do not ask my learned friend to admit that it is due to pollution; we are prepared to prove that ourselves; but if he admits that that is a fact it will relieve us of the necessity of proving it. As for the inference we shall put evidence before you that we hope will convince you that our inference is correct.

1912. (*Chairman.*) Do I rightly understand you to say that you impeach the river from Waterloo Bridge down to Gravesend?

1913. (*Mr. Browne.*) Yes.

1914. (*Chairman.*) And you say that that state of things is attributable to these works of the Metropolitan Board?

1915. (*Mr. Browne.*) Entirely to them.

1916. (*Chairman.*) You say that some of the sewage finds its way back from the outfalls even as far as Waterloo Bridge?

1917. (*Mr. Browne.*) Yes, distinctly so, my Lord; and if I may refer to what the witness said in answer to your Lordship, he said that the water moves more up on the flood than it moves back on the ebb.

1918. (*Chairman.*) I thought it had been said that they had experimented upon it and found that it did not go above Greenwich.

1919. (*Mr. Browne.*) We have had very careful experiments made, and at the right time we will lay them before you.

1920. (*Mr. Bidder.*) The admission that I have made to my learned friend Mr. Beaumont Morice, of course, applies to my learned friend Mr. Balfour Browne's benefit too, as far as it goes; but as to admitting that fish do not live between the outfalls and Waterloo Bridge, I cannot admit that, because I happen to know that they do live.

1921. (*Mr. Browne.*) And I happen to know that they do not.

1922. (*Chairman.*) You say, Mr. Bidder, that although the fish may be poisoned by the outfalls, the water is not thereby polluted?

1923. (*Mr. Bidder.*) I do not think, my Lord, I used the word "poisoned." I do not for a moment admit that fish have been poisoned. I have good reason to know that they have not. The fact which I admit is that fish are not to be found where they used to be found, and that it is not as a rule found expedient to bring them living in the wells from below the outfall to above it.

1924. But you say that that is not owing to this discharge from the outfalls.

1925. (*Mr. Bidder.*) I will leave my learned friend to draw any inference he likes from it.

1926. (*Chairman.*) But supposing that it is, do you still say that there is not a pollution of the water?

1927. (*Mr. Bidder.*) Yes, my Lord.

Adjourned to Friday next at half-past 1 o'clock.

---

# FIFTH DAY.

## Friday, 17th November 1882.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary*

Mr. WILLIAM BRILL called in, and examined by Mr. BEAUMONT MORICE.

*W. Brill.*
*M* ——
17 Nov. 1882.

1928. You, I believe, live at Woolwich?—Yes.

1929. And I believe you have been a fisherman for a considerable time?—Nearly 50 years.

1930. Can you tell us if you remember when the sewage outfalls were opened?—To the best of my knowledge about 17 or 18 years ago.

1931. What was the state of the river before they were opened?—It was in a very pure state.

1932. Where did you generally find the best fishing ground in the river?—From Greenhithe to Blackwall.

1933. (*Chairman.*) You may take this very shortly, for there has been no cross-examination upon it. (*To the witness.*) Since that time you have not found any fish there?—No; not this side of Erith since the opening of the outfall.

1934. (*Mr. Beaumont Morice.*) How far have you to go down the river in order to get fish?—To the Lower Hope—not this side; that is about 10 miles below Gravesend.

1935. Used you to be able to get any worms or bait in the river?—Yes, there used to be a worm bred in the mud. Fish used to feed ashore on the mud.

1936. What kind of worms were they?—They were a sort of red worm.

1937. (*Chairman.*) And those worms have disappeared?—Entirely.

1938. (*Mr. Beaumont Morice.*) Do you remember the state of the shore down the river on the south side; was it fairly clean?—Yes, it was clean all the way down previous to the sewage coming down, and we could go and work our net along shore, and catch a large quantity of fish.

1939. How has it since altered in character?—From the time that the outfalls have discharged into the river there has been nothing to be caught along shore this side of Long Reach.

1940. But has there been a dry hard shore like there was before?—No; all slushy muck; nothing could live on it.

1941. Is that mud, or what is it?—It is imitating a cesspool more than anything.

1942. When you say "imitating a cesspool," do you mean that it smells?—Yes, very strong.

1943. Do you know the Erith Bight from Jenningee Point?—Yes.

1944. What is the state of the tide there; does it veep round?—The tide sweeps round from Jenningee Point and down Erith Reach, and settles in Erith ight principally. The tide sets direct into Erith ight.

1945. Do you know the part that is called Church ole?—Yes, that is between Jenningtree Point and rith, opposite the church.

1946. Do you know whether there is any deposit ere along the shore?—I remember, previously to the werage, that there used to be a great deal of water Church Hole, and now it is quite shallow with a slushery" mud.

1947. How long has that been the case?—It has en getting worse and worse every year. I should ink the time I noticed it particularly is eight or ne years ago.

1948. Has there been any alteration in the last few ars more particularly?—Oh yes; it is growing very st lately, and in fact all along Erith.

1949. Have you noticed whether the sewage which ttles there is washed away at all by the action of the de?—If it does wash away it very soon appears gain.

1950. Then do I correctly understand you that it creases?—It still increases.

1951. Have you noticed any smell from that part?—Yes.

1952. Can you tell us what the smell is like?—I annot compare it to anything else than a smell from privy.

1953. Have you ever felt any bad effects from the mell?—No, I have not; it has never affected me.

1954. You go up and down the river a good deal?—Yes, I go up and down the river. I have frequently ad to put my handkerchief to my nose because of the ench.

1955. Have you ever been in the habit of drinking e water or of washing in the river?—Yes, I have runk it between Erith and Greenhithe.

1956. When was that?—A long time ago, previous the sewerage; nearly 20 years ago, I should say.

1957. Have you done it lately?—No.

1958. Do you know, from going up and down the ver, how far the sewage goes?—I should think that the farthest it does not reach lower than the lower art of Gravesend Reach.

1959. (*Sir John Coode.*) What makes you say that; ave you had any occasion to observe specially that art of the river?—Yes, we keep fish in the boat's ell, and as soon as this sewage water comes down e have to shift lower down to keep our fish alive.

1960. How do you ascertain that you have passed ut of the sewage water?—We can tell by our fish.

1961. But I thought the fish were out of the water?—No; we keep them in the well, and as soon as we nd the bad water coming down we watch the fish nd we shift our boat.

1962. Can you tell by the action of the fish then?—Yes; as soon as the fish begin to taste bad water they fly about like mad, and if we were not to shift the boat they would very soon be all dead.

1963. Then by what do you judge that the water is fit for you to put the fish into again with safety?—We can always tell by experience. When we get lower down on the flood tide it forces the water back again.

1964. Then is it the difference in the colour of the water?—Yes, there is a difference.

1965. In the appearance of the water?—In the appearance of the water.

1966. (*Mr. Beaumont Morice.*) What is the appearance of the water when you are in the sewage?—It is of a very greasy nature.

1967. Does it have any effect upon your boats or nets?—Yes.

1968. In what way?—If we were to work a net in the sewage water it would very soon get rotten.

1969. What colour is the sewage water?—It is a sort of green greasy nature to look at it.

1970. Have you ever found any lumps of sewage there, as well as the liquid sewage?—Yes, plenty.

1971. Whereabouts do you generally find them?—You will find them nearly all over the river, as the discharge comes.

1972. Have you ever found any of the sewage above Crossness?—Yes.

1973. At what part can you put the fish into the water again?—Not before you get above Greenwich or Limehouse; about there.

1974. How lately have you been fishing?—I have not been fishing now for nearly a twelvemonth. I had a misfortune.

1975. Up to last year you were fishing?—Yes. A little later than this I had a misfortune. My boat sank, and I lost my gear, and I have not been able to replace them.

1976. Up to last year you have been fishing?—Yes.

1977. Is the mud, or the muck as you call it, that you have noticed on the bank anything like the mud that used to be in the river?—Do you mean where the tide flows over?

1978. Yes, the ordinary Thames mud?—Oh dear, no; not a bit like it.

1979. Do you know anything of the River Medway?—No.

1980. Why do you tell us that the mud now is different from the mud that there used to be?—Because it used to be a hard pure mud; you could walk in it and it would only come half up to your knee, and now if you got into it it would come up to your middle; it is slushy.

1981. Is there any smell from it?—Yes.

1982. When do you find it smell worst?—It is almost always very bad.

1983. But is there any time more than another when you find it smell?—If the weather is warm you will find it very, very bad.

Cross-examined by Mr. Norman Bazalgette.

1984. I understand you to say that the fish have now all gone down below the Lower Hope?—Yes.

1985. And the Lower Hope you say is about 10 miles below Gravesend?—Nine or 10 miles.

1986. Is it not about 5½ miles; have you ever measured it?—I have not.

1987. Then you are speaking simply from your impression; you have no knowledge of the fact?—I have no knowledge of the fact.

1988. You say that all these red worms have disappeared; where have they gone to?—They are destroyed in the mud.

1989. Then they do not exist in any part of the river now?—Not this side of the Lower Hope.

1990. Do you find them when you get down to the Lower Hope?—No. I think not. I think there are not any there, because it is of a very sandy nature.

1991. Then they have disappeared from the river altogether?—Yes, where I have been fishing.

1992. You are a good deal on the river are you not?—Yes.

1993. You enjoy pretty good health, I suppose?—Yes, very good health.

1994. You have not a very large doctor's bill to pay?—Not very.

1995. You say that about 20 years ago you used to drink Thames water?—I did.

1996. Then you left off drinking Thames water some years before the outfalls opened, I suppose?—It is 20 years ago; but it is previous to the sewage coming in.

1997. You left off drinking Thames water at any rate before the outfalls were opened?—Yes.

*. W. Brill.*
Nov. 1882.

Re-examined by Mr. BEAUMONT MORICE.

1998. Can you tell us when you left off drinking Thames water?—Not exactly to a year or two.

1999. (*Sir John Coode.*) Why did you leave it off?—Because it was not fit to drink.

2000. And you cannot tell us the date?—No, I cannot tell you the date.

2001. You said it was before the outfalls. How long was it before the outfalls?—I cannot say how long it was before the outfalls.

2002. (*Mr. Beaumont Morice.*) Where used you to take it from when you drank it, as a rule?—I used to get it out of the river.

2003. But what part of the river?—In the middle mostly.

2004. But up any particular reach?—Not a particular reach. I have drunk it at Erith, and I have drunk it at Greenhithe, and higher up.

2005. With regard to the worms, you do not generally find worms in sand, do you?—No.

The witness withdrew.

*Mr. Young*

Mr. GEORGE YOUNG called in, and examined by Mr. BEAUMONT MORICE.

2006. You live at East Greenwich, and you have been engaged in fishing for a great number of years?—Yes, 40 years I have been fishing.

2007. (*Chairman.*) Down to the present time?—Up to last Sunday. I was up with a cargo of fish last Monday.

2008. (*Mr. Beaumont Morice.*) Do you remember the time when the outfalls were opened at Crossness and Barking?—Within a few months, I dare say.

2009. What was the state of the river before that time?—We used to catch shrimps, whitebait, flounders, and eels up at Greenwich.

2010. Down to what part of the river?—Down as ar as Erith. Erith Rands used to be our principal place for fishing.

2011. How long were you able to keep fishing in Erith Rands?—I should not think it lasted more than about two years after the sewage came into the river. It kept getting worse and worse.

2012. What did you have to do then?—It kept driving us away. We went to Greenhithe, and from Greenhithe to Gravesend, and from Gravesend to Lower Hope.

2013. And you were not able to get the fish that you had got before?—No.

2014. Then you say you were driven further down?—Yes.

2015. Where do you have to go to now for fish?—To the river Medway.

2016. Do you know the Medway at all?—Yes.

2017. What is the nearest point up towards London where you can catch a fish of any kind?—I do not know of anywhere, without it is the Lower Hope; that is about seven or eight miles below Gravesend.

2018. That is the nearest point to London?—Yes, that is the last I have caught there. The last time I was fishing there we caught a few, and they were very scarce then, and then they would not live on the low water.

2019. Then you have to go between the Lower Hope and the Medway?—Yes.

2020. You know the river very well; what sort of shore is there down by Jenningtree Point, along Erith way?—The banks are very well, but the bottom is nothing else but all filth. I lost an anchor there once; I was caught in a gale of wind, and I tried to sweep after it with a small line, and when I hauled my line in it was, I should think, three inches thick with muck and paper, and all manner of filth.

2021. Do you know whether there is any mud, or anything like mud, on the south shore down from Jenningtree Point?—Not pure mud; it is all filth.

2022. Why do you say it is filth?—Because I can prove it by a staff.

2023. Is there any smell to it?—Dreadful.

2024. What is the smell like?—Closet stuff more than anything else. If you put your hands overboard in it, you have a hard matter to get your hands clean again.

2025. From going up and down the river, can you tell us how far the sewage in the river goes down, on the ebb tide?—The fish would not live at Gravesend on the low water. I think it goes about there.

2026. That is the way you are able to tell?—Yes.

2027. How do you find that fish will not live there?—No longer ago than last Sunday evening I was sailing up with all my fish in the water, and when I got into Long Reach I had to sweep my fish out, and spread them all about the vessel till I got to the Upper Pool in London, and then I put them into the water, and they lived then.

2028. (*Sir John Coode.*) When you say that you had to pull them all out, why did you have to do so?—Because they were just the same as if they were drunken men, with the filth of the water.

2029. (*Colonel Ewart.*) But where did this begin?—In Long Reach; it was on the high water time.

2030. (*Mr. Abernethy.*) You came up on the flood?—We came up on the flood, and it was about an hour-and-a-half ebb.

2031. (*Sir John Coode.*) Might not that have happened if the water had been fresh water and free from sewage?—No.

2032. The fish that you had caught were salt water fish, I suppose?—That does not matter; they will live in good fresh water, because I put them in fresh water when I was in the Upper Pool.

2033. Did they not seem like drunken men then?—No; the water is pure and good at London.

2034. (*Mr. Beaumont Morice.*) Does the water have any effect upon your boat or nets?—Where our nets wanted tanning once a month we have to tan them every week now, or else they would rot away; and then with regard to the boats' bottoms, if you dressed a boat's bottom at one time you could let it go for two or three weeks; but now, every time you come up she wants her bottom scrubbed.

2035. Was there at any time any hard bottom or shore down the river near Jenningtree Point, or Erith?—At one time of day there was. There was good food for fish then. There used to be a nice hard sandy bottom, with a little red worm, which the fish used to feed on.

2036. Are there any of those worms left now?—No, nothing at all would live there.

2037. Do you know whether there is any settlement of filth in the Bight?—I have proved it by losing an anchor, and I tried to sweep the anchor with a sweep line and it went right under, and I tried with a staff, and I could shove the staff down 6 or 8 feet all in filth.

2038. Do you know the Causeway at Erith?—Yes, perfectly well.

2039. Has there been any alteration in that in the last few years.

2040. (*Chairman.*) It has been lengthened, has it not?—I think it has been lengthened.

2041. (*Mr. Beaumont Morice.*) Do you know whether there is any deposit of this stuff near that causeway?—It runs all down there.

2042. But has there been any increase in the last few years?—Wonderful.

2043. Used you ever to use that causeway to moor your boats to?—Yes.

2044. Can you do so now?—No, we never moor there now.

2045. Why?—It does not trouble us, because we do not fish there.

2046. Could you do it if you wanted to?—I do not believe that an anchor would hold if there was any wind at all, for it is all of a "slather."

Examined by Mr. Lumley Smith.

2047. Below the place where the sewage affects the water, are the worms found still where they used to be found?—No, there are no worms found there at all.

2048. That is where the sewage comes?—All the way down the north side and the south side; each side is poisoned.

2049. (*Chairman.*) Do you find any at the Lower Hope?—No, the fish will not live there at low water if there come two or three calm days; it is only a breeze of wind that keeps the fish there, if they are there.

Cross-examined by Mr. Norman Bazalgette.

2050. I understood you to say, as to the wind, in Half-way Reach, that the banks were very well, but that the bottom was all filth?—The banks were very well—the saltings.

2051. I presume you will agree with me that the banks are the parts which are exposed to the air?—The banks are where you walk along, and the saltings are different altogether; the saltings are outside the banks.

2052. The banks are very well?—That has nothing to do with it. It is only to keep the water out of the marsh; but the saltings are a different thing.

2053. Are you much upon the river?—Yes, winter and summer.

2054. Do you enjoy pretty good health?—Not when I am about Erith. I cannot a-bear it. I dare say you have experienced the same feeling as I have when you have been going down in a steamboat.

2055. Do you mean that you have been actually taken ill, and had to consult your medical adviser?—Not exactly that. If I am aboard of a steamer I am very glad to go and get three penn'orth of brandy for to cheer myself up a bit. I am forced to put my handkerchief up to my nose to keep the smells away and not only me, but the other passengers as well.

2056. How often do you go past there in a day?—Not often in a day.

2057. Then you do not often have to apply this remedy?—No, it would not do.

2058. You told us that the fish would not live at Gravesend, and it is from the disappearance of the fish that you judge that the sewage comes there, is it?—It is. Of course the sewage water reaches there.

2059. Then you may catch fish at one point, and half a mile higher up you may not catch them at all?—That may be so at times.

2060. Can you tell me by eye, or nose, the difference between the point where you can catch the fish and the place where the fish disappear: is the distance half a mile?—Half a mile is only a short distance. I would not say for half a mile. It might be a mile and a half.

2061. Therefore, the absence of the fish is the only indication that you have of the presence of the sewage?—That is all.

2062. You told us just now that you had to tan your nets once a month?—We used to, but now we have to do it every eight or nine days.

2063. Do you still fish in the Thames?—At times at the Lower Hope. That is the highest we can fish.

2064. And you have to tan your nets once a week at the Lower Hope?—Yes.

2065. And you attribute that to the sewage?—Certainly, nothing else rots the twine but that. That is what all our fishermen reckon it is.

2066. But you find the fish at the Lower Hope?—At high water. But at low water there are none. You might find fish at high water at Gravesend, but there are none at low water.

2067. Am I to understand as the result of your evidence that there are no red worms to be found in the Thames now?—For a certain distance.

2068. Where can you find them now?—I do not know. I cannot answer that question.

2069. Can you find any above the outfalls?—I do not think you can without it was well up the river. You might get some there.

2070. I ask the question because I heard you talk about a nice sandy bottom with red worms in it?—It used to be.

2071. You are speaking of times long gone by?—Not of the present time.

2072. You know of no red worms to be caught in the Thames just above or below the outfalls?—No.

Re-examined by Mr. Beaumont Morice.

2073. With regard to this fishing, I understand you to say that you have been driven down the river?—Yes, every year.

2074. As a matter of fact, do you attempt to fish above the Lower Hope?—The last time I shot my lines was off Grays, and I baited them with whitebait and shrimps, on purpose to see whether the fish would take either, and I never saw the sign of a fish at all. The baits came in on the hooks just the same way as I shot them off.

2075. That is at the top of Northfleet Hope?—Yes, right off Grays; that is where I shot my lines. That was just before that heavy gale of wind.

2076. Then, as a matter of fact, you do not get any fishing up in this part of the river at all?—No, none at all.

2077. With regard to what you were asked about the banks, that is above what you have been talking about as to where the mud is?—The bank is.

2078. It has nothing to do with the slushy part?—No, there are the saltings astride the bank.

2079. Is or is not this deposit of slush a distinct thing from the bank and from the saltings as well, and what is the difference between what you consider deposit and what you consider mud?—You must understand that at high water and at low water the tide is at a standstill, and that has time to settle a bit till the tide begins to run again; and then it moves it a bit, so that the mud cannot be such a great way up. The mud does not reach the bank. The bank has nothing at all to do with the bottom of the river.

2080. So that the bank has nothing to do with it?—No.

2081. I take it from you, that whenever you come past Erith, and the reaches above Erith, you smell this smell that you have told us of?—Yes, and not only that, but directly the fish touch the bad water we are forced to sweep them out and spread them out about the vessel.

2082. And of that you had experience quite recently?—Only on Sunday.

2083. (*Sir John Coode.*) If an inch rope came in three inches thick, owing to the quantity of mud that accumulated round it, how was it that the bait came in as clean as when you first put it overboard?—I said the bait came in whole; it had not been touched by the fish.

2084. But if the inch rope became coated three inches thick with mud, how is it that the bait came in so clean and whole?—It did not come in so clean.

2085. You said just as clean, you meant just as whole?—The hooks are bound to catch this stuff, paper, and all sorts of things.

2086. (*Chairman.*) The bait was all foul as well as the rope?—Yes, all much alike. I meant whole; not touched by the fish.

The witness withdrew.

*Mr. T. H. Sibley.*

17 Nov. 1882.

Mr. THOMAS HARRY SIBLEY is called in; and examined by Mr. BEAUMONT MORICE.

2087. You live, I believe, at Erith, and you are foreman and lighterman for Messieurs Pigou and Wilkes?—Yes, through Mr. Brydges.

2088. Do you know the river?—Yes.

2089. What are your duties as regards the river?—At present to see the craft loaded and unloaded in the Magazine Creek at Halfway Reach, just below the outfall.

2090. What is the state of the river, so far as you have seen, at that part?—Very filthy.

2091. What do you mean by "very filthy"?—In a filthy state, owing to the refuse that comes from the outfalls.

2092. Is there any smell, or anything offensive about it?—Yes, very much so in hot weather.

2093. What is the smell like, in ordinary language?—I can compare it to nothing else than a parcel of dead bodies floating about.

2094. It smells like that?—Something similar to that.

2095. A rotten sort of smell?—It is so.

2096. Is there much mud about in that creek?—I do not know so much about mud; there is a lot of slush that we have to encounter.

2097. What is the slush like?—I can compare it to nothing but sewage.

2098. What is the colour of it?—It is more like night-soil than anything else.

2099. Does it smell offensively, then?—Yes, very.

2100. Is there much of it there?—A very great deal.

2101. Does it increase at all?—Yes, wonderfully.

2102. Do you do anything when you find that it is increasing so much?—If it was not for the sluice that we have to carry it away in our Magazine Creek, in less than six months, I suppose, we should be blocked out there altogether, and we should not be able to get in.

2103. You have a sluice, you say?—Yes.

2104. And you open this sluice and that clears it?—Yes; and we keep the water in; and when the tide is going down we open the sluice again to make our roadway into the creek navigable, so that we can get in and out.

2105. That is to say the creek fills up with this sewage stuff?—Just so.

2106. And you have to cleanse it with a sluice?—Yes, and we do it frequently.

2107. How often do you do it?—About every fortnight.

2108. How long have you been there at work?—I have been working in and out there, 16 years.

2109. Were you there before or after the outfall was made?—I went there just after the outfall was opened.

2110. A short time afterwards, I suppose?—Yes.

2111. When you went there did you have to do this sort of thing that you have been describing?—No; I do not know that we used to do it more than once in three months.

2112. From what period have you had to do it as often as once a fortnight?—It is owing to the settlings that come from the sewage.

2113. For how many years have you had to do it so much oftener?—I should think for these last 10 years.

2114. And at the time you came, I understand, the outfalls were just opened?—They were just open.

2115. Is there any stench about this stuff?—Yes, a great lot.

2116. Have you ever felt any ill effects from the stench?—So much so that sometimes in hot weather we have had to knock off work.

2117. You say "you"; there are several of you, are there?—Yes, there are five or six as a rule. We have had to knock off work, and we have felt very queer at the time.

2118. How long have you known the river altogether?—Something like 24 years.

2119. Was there anything like this to your knowledge before the outfalls were opened?—Never.

2120. What was the state of the river then at that place?—There was nothing, only mud then, which is of course more sand than mud, according to how the tides run.

2121. Do you know anything of the shore between Jenningtree Point down Erith way?—Yes.

2122. Do you know whether there is any deposit or collection of mud or anything else there?—A very great deal in Church Hole.

2123. Church Hole is halfway between Jenningtree Point and Erith, is it not?—Just so.

2124. What is the sort of stuff that collected there?—Nothing but sewage, from what I can see of it. I can remember the time when large ships used to bring up in Church Hole; and now there is no water there at all scarcely.

2125. Is there any tide round there in Church Hole?—There is an eddy-tide, sometimes, on the ebb-tide.

2126. Has there been any settlement of this stuff there?—A great deal.

2127. Has there been much for the last few years more particularly?—Yes.

2128. (*Chairman.*) That is not disputed. It was quite plainly admitted, I understood, that there was a great settlement in Erith Bight. The explanation that will be offered by Mr. Bazalgette will be different from yours; but the fact that there is a great silting there, is really beyond question, I think.

2129. (*Mr. Beaumont Morice.*) I think my learned friend's admission had reference more to the bank in Halfway Reach.

2130. (*Chairman.*) That is also admitted.

2131. (*Mr. Beaumont Morice to the witness.*)—Has this state of things, about which you have been speaking, remained about the same for the last few years, or has it increased?—I think it has increased very greatly.

2132. Have you ever noticed anything of the sewage in the water?—Something of all sorts.

2133. Has there ever been anything on the water that you have noticed like sewage?—Yes, plenty of times.

2134. Have you ever noticed anything being taken out of the river?—Yes, I have.

2135. What have you seen?—Grease in particular. I have seen people come inside of our Magazine Creek and collect something like half a hundredweight of grease at a time; and I firmly believe that several parties get their living by it.

2136. How do they collect it?—With a small net with a handle to it, and a boat, and they skim it up.

2137. Is there any particular time of the tide at which they do that?—Generally speaking when it is high-water time with the wind on the land.

2138. At what time does the sewage begin to come out?—Something about high-water time.

Cross-examined by Mr. NORMAN BAZALGETTE.

2139. How long have you been in your present situation?—Sixteen years.

2140. When you first came there which of these places was within 300 yards of Magazine Creek, Johnson's Fish Manure Works, Bevington's Manure Works, Collins's Manure Works, and the Belvedere Guano Company; they are all within 300 yards at the present time are they not?—I do not think so.

2141. Take the nearest, Johnson's Fish Manure Works are within 300 yards, are they not?—Yes, and over. We are the nearest to the outfall.

2142. Are you 300 yards or not from Johnson's Fish Manure Works?—I should think we were.

2143. Then immediately adjoining Johnson's Manure Works you get Bevington's Manure Works, do you not?—Yes.

2144. Then immediately adjoining Bevington's Manure Works you get Collins's Manure Works; is that right?—Yes.

2145. Then immediately opposite Magazine Creek you get a candle factory and Crossfield's Manure Works, do you not?—Yes, on the other side of the water.

2146. Which of those manure works were in operation when you first of all came to Mr. Brydges?—The Belvedere Works.

2147. They were the only ones?—They were the only ones so far as I know.

2148. The Belvedere Works have gone, have they not?—No; they call it the Belvedere Wharf now.

2149. Are the works still in operation?—Yes.

2150. Then I have a fourth one to add.

2151. (*Sir John Coode*). This Magazine Creek is about half way down Half-way Reach, is it not?—Yes.

2152. (*Mr. Norman Bazalgette.*) It is between the southern outfall and Jenningtree Point?—Yes.

2153. With regard to the processes that go on at these different places, can you tell me whether at Johnson's Manure Works, Johnson takes all the blood down from the Cattle Market in London and makes that into manure?—I am not aware of that at all.

2154. Have you ever seen the horns of cattle going into Bevington's Manure Works?—Yes.

2155. Do you not think that these processes might account for the smell of dead bodies that you have mentioned?—How can that be if there is no outfall into the river.

2156. You think it is necessary that they should go into the river before they can smell?—Decidedly; before they could upset the water.

2157. You say that this smell has been continually increasing?—Just so.

2158. You have told me that when you first came to this place, only the Belvedere Guano Company's works were open. Which came next?—I do not know.

2159. Were Johnson's the last? They have been established within the last year, have they not?—I do not know. I do not trouble myself about other people's affairs.

2160. They did not all come in a lump, did they?—No.

2161. They have been established there gradually?—I believe that they have come one after the other.

2162. And the smell you have told us has gone on increasing from time to time?—Yes.

2163. Is this smell to be smelt all the year round?—The particular smell from the land we can smell all the year round; but what I am speaking about is the sewage.

2164. There is a smell from the land, then?—There is a smell from the manure factories which we have to put up with all the year round.

2165. When the wind is blowing in that direction, cannot you get the smell from Crossfield's Manure Works and the candle factory, and from the other side of the river?—Yes.

2166. And that smell goes on all the year round?—Yes.

2167. But does the smell of the outfalls go on all the year round?—We do not smell them so much in the winter time.

2168. Do you smell them at all in the winter time?—Yes.

2169. If you went down the river could you smell them now?—Yes.

2170. And would they be offensive?—Yes.

2171. Most offensive where your works are?—Yes.

Re-examined by Mr. Beaumont Morice.

2172. In fact you have that smell all the year round?—Yes.

2173. And it is merely a question of how the wind is whether you get it?—Of course we get it most when the wind is on the land; anything from the north-west we are bound to get it.

2174. Are you perfectly clear that that is a distinct thing from this sewage smell?—Yes.

2175. You have no doubt about that?—I have no doubt at all.

2176. You say that there was only about one of those factories when you came there?—Only one.

2177. You were asked about Johnson's; do you know that it was established under the control of the Erith Local Board?—I do not know what it is established under.

2178. But it has been only recently established?—I believe not.

2179. As to this smell of dead bodies, you say that it could not have come from these land factories?—No, it is a different smell altogether; the sewage has a different smell altogether from the smell of those factories.

2180. You say that this sewage smell comes from the water and not from the land?—Yes, from the water and not from the land.

2181. And you live alongside of the water?—Yes, close to it.

Examined by the Commissioners.

2182. (*Colonel Ewart.*) About these works that you have been speaking of, have you ever noticed any discharge of refuse or effluent water from those works?—No, none whatever.

2183. Are there any gasworks about there?—No; only at Erith.

2184. Have you ever noticed any discharge from them?—No, nothing.

2185. (*Chairman.*) You do not go up and down the river, do you?—Yes, I do. I sail up and down the river, and I frequently walk up and down the bank.

2186. I understood you to say that your business was to see to the loading and unloading of barges?—Just so; but I go on board the craft that go up and down, and I likewise walk up and down.

2187. (*Sir John Coode.*) You knew this part of the river, I think you said, for about eight years before the sewage outfalls were opened, and the outfalls have been opened 16 years; that makes 24 years altogether?—Yes, I knew the river, but I was not in these works at that time.

2188. Did you know this part of the river well?—No; I was more down below at that time.

2189. Then you cannot tell us, of your own knowledge, what was the condition of those banks before the outfalls were opened?—No.

2190. You have spoken of the accumulation in Church Hole. We have been told that that has been brought about in a great measure by the operations of the Thames Conservancy in dredging at or near Coldharbour Point; have you any knowledge which will enable you to tell us whether this deposit in Church Hole is due to the change in the set of the tide, because we are told, on the one side, that it is, and on the other that it is not. Have you noticed any difference in the set of the tide since the dredging operations of the Thames Conservancy near Coldharbour Point?—No, I have not.

2191. You think the tides set the same as they did before?—As far as I am concerned, I believe they do.

The witness withdrew.

Mr. William Henry Joseph McKee called in; and examined by Mr. Beaumont Morice.

*Mr. W. H. J. McKee.*

17 Nov. 1882.

2192. I believe you live at Erith?—Yes.

2193. And you are foreman and lighterman to Messrs. Berry and Edwards?—Yes.

2194. Do you know the River Thames pretty well?—Yes, I have been on the river about 18 years.

2195. What are your duties on the river?—I am a gunpowder lighterman.

2196. How long have you been in your present employment?—Ten years next March.

2197. In what part of the river are you generally stationed?—Our magazine is at Jenningtree Point in Halfway Reach.

2198. Do you remember the river before the outfalls were opened?—No, not much.

2199. How long was it after the outfalls were opened that you went to Jenningtree Point?—About seven or eight years I suppose.

2200. Can you tell us what was the state of the river or the creek then?—It was pretty well like it is now, I should think.

2201. (*Sir John Coode.*) If I understand aright, you are not employed at the same magazine as the last witness?—No.

2202. Your magazine is at the Point and not in a creek?—At the Point, at Jenningtree Point, Messrs. Curtis and Harvey's magazine.

2203. (*Mr. Beaumont Morice.*) Can you tell us what is the state of the river?—At high water it is all dark fluid, and the stream comes away down from the sewers.

2204. How can you tell that it is a stream coming down from the sewers?—You can see the floating masses of excrement and that sort of thing.

2205. Do you see these floating masses constantly?—Yes, every day.

2206. At what time of the tide?—It commences just at high-water time.

2207. (*Sir John Coode.*) How can you account for ts coming down from the outfalls at high-water time when you are a mile, or a mile and a half, below the lowest outfall?—It comes away just after high water; there is an eddy tide where the magazine is, right along the shore.

2208. What you mean to say is that there is an eddy on the flood which brings this down from the outfalls before the time of high water?—Yes, there is an eddy inshore, the tide runs down inshore about two hours.

2209. (*Mr. Beaumont Morice.*) Then you find it every day, you say, coming down that way?—Yes.

2210. You have to do with a good many barges, have you not?—Yes; we have eight barges.

2211. Does it have any effect upon those barges?—They have been complaining many times in the summer time, about the stench and smell.

2212. (*Chairman.*) But the barges would not suffer from that. Mr. Morice asked you whether the barges were affected in any way?—Their sides get covered with slime.

2213. (*Mr. Beaumont Morice.*) And besides that, the bargees complain of the stench?—Yes.

2214. Do you notice any alteration in the colour of the water when the sewage comes down?—It is brown and thick.

2215. When you are there, is there any stench from it perceptible to you?—In the summer time there is.

2216. What sort of stink is it?—I can hardly say; it is very offensive.

2217. What should you call it?—Sickening, I should say.

2218. Do you ever find anything in the stream coming down with the sewage beyond the mere look of the water in a liquid state; are there any lumps?—You see a lot of lumps floating about.

2219. Does that occur often?—Yes, very often.

2220. And you say you generally find them in hot weather?—Yes.

2221. Are you near any of these factories on the shore, the glue factory, and so on?—About a quarter of a mile from the nearest I suppose.

2222. Do you find any smell from them?—Yes, at times.

2223. Are you in the habit of getting ballast from the river?—No.

2224. Do you know whether it is done?—Yes, in Long Reach now.

2225. Can you say whether or not the smell from these factories is anything like what you have been telling us about?—No; it is a different smell altogether.

Cross-examined by Mr. Norman Bazalgette.

2226. The smell from the factories is entirely distinct from that from the river?—Yes.

2227. What is the difference between them?—A great difference. The other is more manure.

2228. Which is the most manure?—The factories.

2229. They smell more of manure than the sewage does?—I think so.

2230. I think that at Jenningtree Point you are particularly favoured as regards these nuisance factories?—Yes, there are several just above there.

2231. Within a radius of 1,200 yards of Jenningtree Point, do you not get Johnson's Manure Works, Bedington's Manure Works, Collins' Glue and Manure Works, the Belvedere Grand Company's Works, Price's Oil Works, the Calendar Bitumen Works, on the one side, and on the other side Crossfield's Manure Works, the Candle Factory, the Rock Portland Cement Company, Barnes' Chemical Works, and another, the Gas Purification and Chemical Works, Wilson's Chemical Works, Miller and Johnson's Chemical Works, and the Fish Manure Works, making in all fifteen?—Yes.

2232. Will you look at the map and tell us whether, according to your view, that is a correct plan.

2233. (*Chairman.*) This is not the kind of witness to prove a map.

2234. (*Mr. Norman Bazalgette to the witness.*) You know all those places that I have mentioned?—Yes.

2235. Can you, in any wind that blows, escape some of those factories. Are you not completely surrounded by them?—Yes.

2236. You are bound, no matter what wind is blowing, to get the smell of some of them, are you not?—Yes.

2237. Does this smell, that you say proceeds from the outfalls, go on all the year round?—Yes, we do not smell it so much in the winter.

2238. (*Chairman.*) You said that you smelt it in the hot weather, as I understood?—Yes.

2239. (*Mr. Norman Bazalgette.*) But it does go on all the year round?—The sewage keeps flowing.

2240. But is the smell perceptible all the year round?—No, not so much.

2241. Have you been down at your works to-day?—No.

2242. When were you there last?—Yesterday.

2243. Did it smell then?—Not a great deal.

2244. (*Chairman.*) Did you perceive the smell at all?—No, I do not know that I did.

2245. (*Mr. Norman Bazalgette.*) Did you smell any of the factories yesterday?—Perhaps they were not at work. The wind was north-east.

Re-examined by Mr. Beaumont Morice.

2246. In the first place it depends upon the direction of the wind what you smell?—Yes, from the factories.

2247. And secondly, are those factories constantly working?—No, I do not know that they are.

2248. You know that sometimes they knock off for a few days?—Yes.

2249. (*Mr. Norman Bazalgette.*) He has just told me that no matter what wind blows, he must get the smell of some.

2250. (*Chairman to the witness.*) You say you have perceived the smell from the river only in hot weather; last summer did you perceive it at all?—Yes.

2251. How many days last summer do you suppose you perceived that smell; had we much hot weather last summer?—Not a great deal.

2252. Did you smell it ten times in the summer?—Yes, more than that.

2253. Twenty times?—I should think more than that.

2254. Fifty times?—Yes, I would not say but what I did.

2255. Sixty times; that would be two months?—I do not know about the times. It is very offensive in hot weather.

*Mr. W. H. J. McKee.*

17 Nov. 1882.

2256. (*Mr. Norman Bazalgette, through the Commission.*) What kind of health do you, and the men at your place of business, enjoy?—It does not affect me a great deal.

2257. It does not affect your appetite?—No, I do not think so.

2258. Have the men about you been in good health also?—Pretty fair; they have been spitting and complaining about.

2259. They have not left off their work?—No, they have not left off their work.

2260. (*Sir John Coode.*) You say that it does not affect you a great deal; does it affect your health at all?—At the time when it is floating by and when the smell is great.

2261. It is not agreeable, but the question was, does it affect your health?—I do not know that it does.

The witness withdrew.

Mr. John Godfrey Lee called in; and examined Mr. Beaumont Morice.

*Mr. J. G. Lee.*

2262. I believe you are the Corinthian Yacht Club waterman at Erith?—Yes.

2263. How long have you been there?—About a year and seven months now.

2264. How long have you been on the water about that part?—About the Thames, about seven years.

2265. First of all, where is the Corinthian Yacht Club at Erith?—At Church Hole, Erith.

2266. That is just in the bight by the church?—That is it.

2267. What is the state of the river at that part?—Very bad in the last quarter-ebb.

2268. Is there much of a tide in there?—There is an eddy-tide runs up for about an hour half ebb, and then it runs down again for another hour, and all the rest runs up. The sewage runs down, runs round by Erith Pier, and then runs up again, so that we catch it all at our place. It comes back on the last quarter ebb-tide. There is a little flood alongshore on the last quarter ebb, and during the time that the tide is running off it runs up in shore.

2269. What sort of stuff is collected there in this way?—Stuff from the human frame; that is as plain as I can tell you.

2270. That will do. Is there any stench from it?—Yes, plenty on a warm morning. If you walk down there before breakfast and take a few whiffs at it, you don't want much breakfast.

2271. What does it stink like?—Just like what it is.

2272. Is there much of this stuff?—Yes, in calm weather there is plenty of it. There is not so much in breezes, but when it is calm, still weather, it is there by bushels.

2273. Has the direction of the wind anything to do with it?—No, that does not affect it much.

2274. You are close on to the bight?—Right alongside of the wall.

2275. Has there been much more of this recently since you have been there?

2276. (*Chairman.*) One year and seven months he has been there.

2277. (*Witness.*) I have been on the Thames seven years; not at Erith.

2278. (*Mr. Beaumont Morice.*) During the seven years that you have been upon the river, has this sewage increased at all?—I do not see a great deal of difference between now and a year and seven months ago; but it is a lot worse than it was seven years ago.

2279. (*Sir John Coode.*) Has your health suffered from it at all?—Sometimes. You may think I do not look very unhealthy now, and no more I am; but I very often have the headache and am sick from it in the summer, but at this time of the year it does not affect me at all. To my sorrow I have wished not to be there sometimes.

2280. (*Mr. Beaumont Morice.*) Have your family suffered?—Yes; I have a little girl who is never well there. She has been away all the summer, and she has been back about six weeks, and it does not agree with my wife. I have a little boy, and it does not affect him much; I do not think anything would hurt him at all, because I think he is made of iron. My little girl has been away twice since I have been there.

2281. There is a causeway, is there not, about this creek?—Yes, it runs into the river about 350 feet down from the wall.

2282. (*Sir John Coode.*) Is that a private slipway belonging to the club?—That is a private slipway belonging to the club.

2283. It is not the same we have been hearing about.

2284. (*Mr. Beaumont Morice.*) No, this is further up the river than Church Hole. (*To the witness.*) Can you tell us what is the state of that causeway when the tide leaves it?—Yes, I can. In the hot weather, if it is not scrubbed every day it is not fit to walk up and down.

2285. Why?—Because it is all slime and dung, I was going to say (and I might as well have said so) every low-water time.

2286. It is not ordinary mud?—No; you only want to smell it to test it.

2287. Do you find this slimy stuff at any particular part of the year, or generally all the year round?—All the year round as a rule; but it does not affect us so much except in hot weather. In hot weather the smell is the worst. The slime is always there, winter and summer.

2288. That is a mere question of the tide leaving it there?—That is it.

2289. Do the stench and smell get into your throat at all?—Yes, in warm weather; it would choke you.

2290. Does this sewage affect any of the boats that lie about there at all?—Yes, if I cleaned a boat's bottom to-day, and put her off this tide at 4 o'clock, to-morrow morning I should find sewage all over her, and I must not scrub it, or else I shall have it all over alike.

2291. You have to keep the boats constantly scrubbed?—You want to clean and redress the bottoms four or five times every summer to keep them in proper order.

2292. Is any of this sewage stuff that remains there ever washed away at all?—Do you mean, what settles on the mud? If it blows a strong wind from the north-east, sometimes the sewage decreases four or five inches; and if it is still weather, it will create four or five inches in a week.

2293. But in spite of the occasional gales, the whole mass is still increasing?—As I say, it increases in fine weather and decreases in gales of wind, and when there is a gale of wind at high-water time, it is just as bad up at the top as it is at low water on a fine day. It stirs it all up.

2294. You know the river, of course, very well from the clubhouse down to Erith along the bank?—I do not know much about the bank.

2295. Not the bank itself, but the mud?—It is all alike all the way along. It is all a bight there. It has a sort of slaty surface, and underneath it is as

*Mr. J. G. Lee.*

17 Nov. 1882.

black as jet; and if you get it on to your boots or clothes it is hard to get it off. It is more like grease than anything else, and "slicker."

2296. You know the old causeway at Erith?—Yes.

2297. Is there much of this stuff there?—That I cannot answer for. I am not much down there. I am stationed at this one place, and I am not supposed to leave except on duty, so I cannot answer for that.

Cross-examined by Mr. Norman Bazalgette.

2298. Did I correctly understand you to say, in answer to the Chairman, that you had bad health at Erith?—Not bad health exactly. I have been sick several times.

2299. What did you say your family consisted of?—I have two boys and a girl, and a wife.

2300. Do not your children continually play over Erith Causeway; is not that their favourite playground?—No, not at all times.

2301. They are continually there, are they not?—Now and then.

2302. Are they as healthy as most children?—One of them is, and the other is not. That gentleman there (*pointing to a gentleman behind Mr. Beaumont Morice*) knows the little boy.

2303. Did you not tell that gentleman that the little boy never had a day's illness?—He never did.

2304. And he plays about on the Erith Causeway?—Sometimes he strolls there. You cannot always have your hand upon them.

2305. He is a fine little fellow, is he not?—He is as fine a little fellow as you will see in a day's march; like his father.

2306. There is a club-house there, is there not?—Yes.

2307. How many members are there belonging to the club-house?—That is more than I can tell you. There are 470 down on the books.

2308. Do members frequently come down to the club-house, and spend Sunday there?—Not in the club-house; on board the yacht. They come down for an hour in the morning, perhaps, for Sunday recreation.

2309. They come down for a Sunday lounge?—Yes.

2310. How many yachts belong to the club?—I cannot tell you without the books, and I have not brought them with me.

2311. Is the number increasing very rapidly?—Until this summer it has.

2312. Now with regard to the Causeway, you know the Corinthian Causeway, and you also know the old causeway at Erith?—I do not know much about the old causeway. I would not answer for that.

2313. Is there any accumulation of mud at your club causeway which corresponds at all in extent to that at the old causeway?—I do not know anything about the old causeway. I do not suppose I was ever on it more than once in my life. I can stand and see it, though I was never there.

2314. Have you seen the mud there?—I have never seen the mud there, but I have slipped into it on a dark night.

2315. Do you have much accumulation in the immediate neighbourhood of your causeway?—Not much, but it is "slickery" stuff.

2316. Your causeway is built on piles, and the other one is solid, is it not?—That is it. Ours is built on piles with the planks an inch apart.

2317. So that the water can flow under it and through it?—That is so.

Re-examined by Mr. Beaumont Morice.

2318. This Corinthian Club causeway is a comparitively new causeway built by the club, is it not?—It is a comparatively new causeway built by the club; it is private property.

2319. Do you know how many years ago it was built?—It would not be more than three years ago.

2320. With regard to the increase in the number of members, do you know, as a matter of fact, that that is the principal yachting station at Erith in place of the one down at the old peir?—Yes, because the other was broken up, so that they could not make a yachting station there.

2321. Therefore, the yachts come and lie off the Corinthian Club-house in Church Hole?—Yes.

2322. (*Chairman.*) You do not know that they ever lay down below; you have only been there a year and seven months?—They had been lying down at the old club-house before. I have had seven years in the river in yachts.

2323. At Erith?—Partly at Erith, and partly at Grays, and at Gravesend, and all the way down the river.

2324. (*Mr. Beaumont Morice.*) And off the old pier, some years ago, you know that used to be the principal station for yachts?—Yes.

2325. And now they come up to Church Hole?—They do that on account of the dirty, filthy coal at the old pier.

2356. (*Mr. Norman Bazalgette, through the Commission.*) How long has the present Corinthian Club been established in its present quarters?—I think three years last June. I remember its being built very well.

The witness withdrew.

Mr. William Hoskins called in; and examined by Mr. Beaumont Morice.

*Mr. W. Hoskins.*

2327. I think you live at Erith?—Yes.

2328. And you are a lighterman?—Yes.

2329. How long have you known the river?—I am nearly fifty years old and I have been at it all my life time. I have known the river these 40 years.

2330. Do you remember the outfalls being made at Crossness and Barking?—Yes.

2331. What was the state of the river before that time?—Before that time I have seen fishing boats at Greenwich and Erith catching shrimps and the water was clear and fresh.

2332. At Greenwich?—Yes.

2333. Whereabouts down the river did they fish?—From there to Blackwall.

2334. But down the river?—To Erith—Church Hole.

2335. Was there much fishing at Erith in Church Hole?—Yes, I have seen 40 boats together.

2336. When did that come to an end?—I suppose about 14 years since.

2337. Where did they go to?—Down below Gravesend.

2338. Were there any bait or worms found in the upper part of the river formerly?—Yes, from Erith to Woolwich.

2339. What kind of worms were they?—Mud worms we call them.

2340. Do you know yourself where any are found now?—None at all this side of Woolwich.

2341. What do you mean by this side of Woolwich; do you mean between Erith and Woolwich?—Yes.

2342. That is to say, down the river from Erith to Woolwich?—Yes.

2343. Can you tell us up to what time they got worms out of the mud?—I have seen them 9 or 10 years back. I have seen thousands of starlings on the mud feeding on them.

2344. And you say there are not any now?—No.

2345. How far are you in the habit of going down the river?—I am in the habit of going down the river to Gravesend.

2346. In going up and down the river do you notice any alteration in the colour of the water?—Yes, a good deal.

2347. What is it like?—Filth; black.

2348. When do you specially note it; at any time of the day or tide?—Yes, about half tide, half ebb.

2349. Is there any stench with it?—Yes, a good deal.

2350. A very bad stench?—Yes, a good deal at times. When you are rowing a boat through it, it is like a lot of mud.

2351. Of what part of the river are you speaking now?—In Halfway Reach.

2352. In coming down the river can you say how far this sewage goes out with the ebb tide?—Yes, I have been driving bottles from the sewerage three years back to see how far it did extend.

2353. (*Sir John Coode.*) On your own account?—No, I had been engaged to do it. They were gallon bottles.

2354. (*Mr. Beaumont Morice.*) You put these gallon bottles in and see how far they will go down from the outfall?—Yes.

2355. (*Sir John Coode.*) Have you been filling bottles or setting them afloat?—Putting them afloat.

2356. Not filling bottles with the sewage water?—No.

2357. (*Mr. Beaumont Morice.*) How far did they go down?—Down to the "Ship and Lobster."

2358. That is just below Gravesend, is it not?—Yes, They went down as far as that on a strong spring ebb and westerly wind.

2359. (*Sir John Coode.*) Did you always set them afloat at the same period of the tide?—We only went once; only one day. We went from the sewerage on a spring ebb tide on the high water.

2360. I understood you to say that you had been doing it for a considerable period?—No, only one day.

2361. You set them afloat at high water?—Yes; at high water from the sewerage.

2362. (*Mr. Beaumont Morice.*) And they went down to the "Lobster"?—Hardly down to the "Lobster"; to the lower part of Gravesend. They hired me from Greenwich. I do not know who they were.

2363. Of course, from going up and down the river, you know the shore of the river?—Yes.

2364. Along Halfway Reach and around Erith Bight what sort of stuff is there on the north shore?—Nothing but filth; it is not mud at all.

2365. Is there much of it?—Yes, a good deal.

2366. Is there much stench from it?—There is not much stench, but it is grease. It is not mud, it is filth.

2367. Has there been much increase of it during the last few years?—Yes, I think there has; a good deal.

2368. Do you know the Bight, right round from Church Hole down to Erith Causeway?—Yes.

2369. Is there much along there?—Yes, that is just where it is.

2370. Do you know the Causeway?—Yes, I remember when I had only three steps to go in a boat at low-water time; and it has been lengthened 60 feet since that; and now you cannot get within five boats' length at spring ebbs.

2371. Is the stuff alongside the Causeway mud?—No; it is not mud at all.

2372. Is there much depth of it?—Yes; there are four or five inches of this filth. There is plenty of mud underneath that.

2373. Have you ever felt any bad effects to your health from this?—No, I never have.

2374. Does it never make you sick or faint?—No.

Cross-examined by Mr. Norman Bazalgette.

2375. You told us that all the mud worms had disappeared between Erith and Woolwich during the last 9 or 10 years?—From Erith to Woolwich.

2376. What have they done above Woolwich?—I cannot tell.

2377. Have you ever seen any of them above Woolwich?—No.

2378. What made you look for them below Woolwich; you are not a fisherman, are you?—No, I never looked for one. I looked for the birds feeding on them.

2379. What birds?—Starlings. Where you see them, there are plenty of mud worms.

2380. You tell us that you have been "driving bottles;" when did you "drive bottles"?—I think it is three years since.

2381. Was that for Captain Calver?—Well, I cannot tell you.

2382. Who employed you to drive the bottles?—A gentleman at Greenwich employed me; I could find out who it was.

2383. You floated these bottles down to below Gravesend; did they stay at Gravesend or what became of them then?—I took them in the boat and brought them home again.

2384. You did not try how far they would go back?—We never tried it back again.

2385. Where did you start from?—From the sewerage.

2386. That is at Crossness. From there to the "Lobster" is about 13 or 14 miles, is it not?—A little more, I think.

2387. How long were they going down there?—About six hours, I think.

2388. You say your bottles took about six hours to go from Crossness or Barking to the "Lobster"?—We did not go so high as Barking. I do not say they took exactly six hours—the whole ebb tide.

2389. They went down with the ebb tide at any rate to the "Lobster"?—Barely to the "Lobster."

2390. You say that the deposit against the Causeway at Erith is not mud at all; what is it?—All along it is nothing but filth; it is not mud.

2391. How do you know it is not mud?—Because I have experienced it in the boat.

2392. Did you take it in the boat with you?—Yes; I haul ropes in and out of my boat, I do not haul mud in. I haul grease in.

2393. Then it is all grease, is it?—Yes. I will show it you now if you go down to Erith.

2394. Do you know the sewers at Erith that discharge into the river by the Causeway?—There are one or two, I think; but I have nothing at all to do with them.

2395. But you know that there are sewers there?—Yes, there are several; there are four or five there, I know.

2396. (*Chairman.*) That discharge into the river?—Yes.

2397. (*Mr. Norman Bazalgette.*) You say that this deposit smells bad?—Coming from the sewage it does.

2398. Is there any of the deposit down in that part of the river that does not smell, say in Halfway Reach?—Not the water, I do not think.

2399. The water does not smell?—I never smelt it. I smell the stench ashore, but not in the water.

2400. The smell is on the shore, you say?—Yes, the smell is on the shore, from the sewage in the water.

2401. Is the smell on the river as well as on the shore?—What from?

2402. Is there any smell on the river or is the smell on the shore; which is it on, either or both?—I do not understand what you mean. There are plenty of smells up and down the river, but you do not smell any smell in the water, only from the sewage.

2403. Can you distinguish the smell that comes from the water from the other smells?—Yes, it comes up like smoke. The colour of the water is enough.

2404. Which smells the worst, the smell which you get from the air or the smell from the water?—The smell from the water.

Re-examined by Mr. Beaumont Morice.

2405. You get smells from the factories up and down the river?—Yes; that is only for a little time.

2406. Is that anything like what you have been talking about,—the smell from the sewage?—No,

2407. The sewage smell is quite different?—Yes, quite different altogether.

2408. There is no mistake about that?—No.

2408*a*. You have been asked about the drains and sewers going into the river from Erith; do you know much about that?—I do not know much about the sewage at Erith. I have lived there 10 years, but I never took that notice. I have been on the water all my lifetime. I said I knew of four or five.

2409. What do you mean by sewers?—Only drains from butchers and one place and another.

*Mr. W. Hoskins.*

17 Nov. 1882.

Examined by the COMMISSION.

2410. (*Professor Williamson.*) Do you perceive this smell of the sewage at this time of the year?—Yes, at any time.

2411. Do you mean to say that you perceived it to-day?—No, I have not been there to-day.

2412. Would you perceive it in winter as well as in summer?—Not so strong in the winter.

2413. But still you do perceive it in the winter?—Yes.

2414. (*Sir John Coode.*) You seem to know about these butchers' drains at Erith. What becomes of the sewage of the population of Erith?—I do not know. I do not study that at all. I know four or five there.

2415. Public sewers?—Yes.

2416. (*Colonel Ewart.*) When you are passing there do you see these sewers discharging at Erith?—If they kill a bullock, or anything like that, they will discharge.

2417. (*Sir John Coode.*) We shall have some evidence, I suppose, as to how the sewage of Erith is disposed of. How does that get into the Thames?

2418. (*Mr. Beaumont Morice.*) There is one sewer for Erith some distance below the pier.

2419. (*Chairman.*) This witness cannot be expected to give us much information about the sewage.

2420. (*Mr. Norman Bazalgette.*) I do not quite admit my learned friend's version about the sewage of Erith; and I think if there is any doubt about it it would be as well to recall the surveyor of Erith. We shall be prepared with evidence on the point.

2421. (*Mr. Beaumont Morice.*) I am willing to do anything that the Commission desires on that matter; but I may perhaps say, as a resident, that there is one drain below Erith, and a large portion of Erith is drained into cesspools.

2422. (*Mr. Norman Bazalgette.*) The natural way of clearing this up would be to recall the surveyor of Erith, who would put in plans.

2423. (*Chairman.*) Mr. Morice will take his own course about it. (*To Mr. Beaumont Morice.*) Is your surveyor here?

2424. (*Mr. Beaumont Morice.*) Not to-day, but I can have him here on the next occasion if the Commission think fit.

2425. (*Sir John Coode.*) We seem to be agreed that it should be in evidence from the surveyor or some competent witness.

2426. (*Chairman.*) It is suggested that the Erith sewage does contribute in some measure to the general foul state of the river, and one would like to see exactly how the matter stands.

2427. (*Mr. Beaumont Morice.*) It was only on the last occasion that Mr. Bidder mentioned that this was a point that he would bring before the Commission.

2428. (*Sir John Coode.*) If you will recall the surveyor, that will meet the case.

The witness withdrew.

*Mr. C. Faulkner.*

Mr. CHARLES FAULKNER called in; and examined by Mr. BEAUMONT MORICE.

2429. You live at Erith?—Yes.

2430. Have you lived there for a long while?—Yes.

2431. What are you?—To tell you the truth, I am anything. I am a contractor to do anything.

2432. How many years have you lived at Erith?—I have lived in Erith about 63 years.

2433. During this time you have known a good deal about the river Thames, have you not?—Yes.

2434. Has your work chiefly been connected with mud?—Yes, mud work on and off; and I follow it now.

2435. What was the state of the mud in the river 15 or 20 years ago?—I can speak to 45 years back, but 20 years ago it was a pure, salty smell.

2436. How long did that continue?—I should say from that time it went on in that way for four or five or six years.

2437. When did it alter, if it did alter?—It began to alter about 15 or 16 or 17 years ago.

2438. How did it alter?—There were bad smells.

2439. Anything else?—No, nothing else; only bad smells, and of course it drove the fish away from us; we have no fish now.

2440. Was there fishing at that time?—When I was a boy I have been trawling with a fisherman and got plenty of fish off Erith and above Erith and below Erith.

2441. And now you say the fish have been driven away? What is the water in the river like now off Erith?—The water of course is purer now than it has been for a long while through the rain water, but in summer time if you go and work in the mud you have to wash your hands four or five times before you get the smell out of them.

2442. You have had a good deal to do with the mud about there?—I have.

2443. What is the mud like now off Erith?—Black mud; you might say it smells more like night-soil than anything else.

2444. Is there much of it?—It is "created" on the shore at Erith. I should say a foot and a half thick.

2445. This night-soil?—This black stuff that comes down.

2446. (*Sir John Coode.*) When you say "created," I suppose you mean "accumulated"?—Yes.

2447. (*Mr. Beaumont Morice.*) Has that been increasing in the last few years?—Yes; I should say from 20 years ago up till now. We have not so much water there by the ballast wharves by 8 to 10 feet. There is this black stuff.

2448. Whereabouts are the ballast wharves?—You know the "Corinthean Clubhouse" and the old Erith pier; it is between there and all along below the pier.

2449. (*Sir John Coode.*) You are speaking now of the old causeway, I suppose?—Yes.

2450. (*Chairman.*) It is between those two places that the mud has accumulated?—Yes, I should say from 8 to 10 feet.

2451. (*Mr. Beaumont Morice.*) The Corinthian Yacht club-house is in Church Hole, is it not?—Yes.

2452. You know the river from Church Hole down to the Causeway?—Yes.

2453. Is there this stuff that you have been talking about all along there?—Yes.

2454. That is in the bight?—Yes, in the bight.

2455. Is there much tide in there?—No, a slack tide.

2456. There is a sort of eddy-tide sometimes, is there not?—There is an eddy-tide. There is more eddy-tide now than I ever knew, and I have been at the waterside over 55 years.

2457. Does this stuff settle there at all?—This stuff settles there.

2458. (*Chairman.*) There is no question about this, I believe. I think it has been admitted that there is a large accumulation of stuff there.

2459. (*Mr. Beaumont Morice.*) But it is not quite admitted in the sense that I want it admitted, namely, that the stuff is sewage.

2460. (*Chairman.*) What is admitted is, that there is a large accumulation of matter; and therefore we may take it very shortly from this witness that there is an accumulation; but what that accumulation is, he perhaps cannot tell us.

2461. (*Mr. Beaumont Morice to the witness.*) Can you tell us what this stuff that is accumulated is like?—It is black, and seems a regular settling like what you may call closet stuff settling.

2462. Is there any stench coming from that?—Yes, in the summer-time very much. You do not smell it now, but I have looked after Price's and Harvey's oil works, where the barges lie at the present time for eight or ten years——

2463. (*Sir John Coode.*) Are you the contractor for barging from those works?—No; I am contractor for laying the barges level.

2464. (*Mr. Abernethy.*) For the berths?—To lay the berths for the barges.

2465. (*Mr. Beaumont Morice.*) You have to clear out the mud for those berths?—Yes.

2466. Have you had more difficulty in clearing out the mud from those berths lately than you used to have?—Yes, I have more now, and I have actually

at half ebb tide seen the stuff from, you might say, the closet come down by there whole, not washed to pieces.

2467. Has that happened several times?—I have seen it several times. Sometimes I do not have to go there once in a month, and sometimes I go there two or three times in a month, but I always like to catch the tide when the tide is running down and then it sweeps all that stuff away.

2468. You have found this stuff increasing in the last few years more than ever?—Yes, it has increased from 8 to 10 feet there in the last 18 or 20 years.

Cross-examined by Mr. Norman Bazalgette.

2469. I suppose I need not ask you whether you enjoy good health as a general rule?—Well, I have pretty good health.

2470. Have you any family?—I have one or two.

2471. Do they enjoy pretty good health?—They are away; one is at Sydney and one is at Woolwich.

2472. And you have all your life enjoyed pretty good health?—Yes.

2473. You have not enjoyed worse health during the last 20 years than you did before?—Yes, I have.

2474. What has been the matter with you?—I am troubled with the gout sometimes.

2475. (*Sir John Coode.*) I do not think you have told us where you live?—I live at Erith in West Street.

2476. Near the water side?—Yes, and I am obliged to linger there.

2477. Near the river side?—Yes.

2478. (*Mr. Norman Bazalgette.*) You told us, I think, that you got a great accumulation of mud on the ballast wharf?—Yes, round in the bight.

2479. Do you know the ponds on the land at the back of the ballast wharf; do you recognize these ponds (*showing a plan to the witness*)?—I recognize one of them.

2480. (*Chairman.*) Where do you suggest that the pond is?

2481. (*Mr. Norman Bazalgette.*) At the upper ballast wharf.

2482. (*Witness.*) There is no pond at the upper ballast wharf.

2483. Is there one at the lower ballast wharf?—No.

2484. Where is the one that you know of then?—There is one between the upper ballast wharf and the church—what we call Running Water Pond.

2485. Do you know of any ponds for keeping the mud away, ponds that stand full when the water is up and when the tide falls the gates are open and then the mud is washed away?—We call them reservoirs.

2486. Do you know the reservoirs?—Yes.

2487. How many are there?—Two; one at each wharf: one at the upper side of the upper wharf, and one at the lower side of the old wharf.

2488. Will you shortly describe to the Commission the objects for which those ponds are used?—They fill with the tide, and there is a flap that opens and when the tide goes back that flap shuts and keeps the water in the reservoir; and when the tide is down they pull up a sluice-gate and let it all run out.

2489. The object of that is to wash away the mud that has accumulated?—Yes.

2490. How many years have these reservoirs been in existence; ever since you were a boy?—No.

2491. How many years?—I can tell you within a little. It is not above 15 or 16, or I might say 18 years, since the new reservoir was built there.

2492. How long have the old ones been there?—There are two new ones. The old ones are done away with.

2493. (*Chairman.*) The question is this: when were those two reservoirs which you are speaking about made?—I should think about 18 years ago.

2494. (*Sir John Coode.*) Are those the old reservoirs?—No, not the old ones.

2495. (*Mr. Norman Bazalgette.*) When were the old ones first established there?—I have known four in my time; but when the old ones of all were made, I was only a lad.

2496. The old ones were used for the same object as the new ones are used for, were they not?—Yes, I suppose so.

2497. Then that particular place, Erith Bight, has always been subject to accumulations of mud?—No, nothing like it has been the last 18 or 20 years.

2498. But still we have the fact that that old reservoir existed when you were a lad for the purpose of clearing away the mud?—The old one was just to keep the beds clean.

2499. (*Chairman.*) When you were a boy there was an old reservoir there?—There was no old reservoir at that time. When I was a boy I knew nothing about where the reservoir was; but I have helped to make three in my time, one at the old wharf at the lower side.

2500. When was that made?—That was made about 28 years ago.

2501. Is that the oldest reservoir that you recollect there?—That is the oldest of the new ones.

2502. But there was an older one still?—Yes, there was a bit of one there.

2503. When you were a lad?—When I was a young man.

2504. Did not that old reservoir, which existed when you were a young man, receive the tide when the tide made, and was it not opened when the tide fell again?—Of course it fed itself.

2505. And the sluices were opened?—Yes.

2506. That is when you were a young man?—Yes.

2507. Forty years ago?—Yes.

2508. Fifty?—Well, I might say 50.

2509. (*Mr. Norman Bazalgette.*) What is your age?—I am in my 67th year.

2510. You said that there was something, I do not know whether it was the mud or the water, that you could not smell now; were you referring to the mud or to the water?—I tell you that the water is purer now than it is in the summer-time.

2511. When did the water last smell?—I am not always by the water side.

2512. But when did you last smell it so as to find it offensive?—The last time I was using my hands in the mud is about a month ago; and you are obliged to wash your hands. I look after Price's Oil Works and Harvey's Works, and if you go and handle the mud there, you smell it.

2513. I am very much obliged to you for that information, but you have not answered my question yet. When did you last smell the water so that it was offensive to you?—I do not smell the water. It is about a month ago since I was in the water with my water-boots on.

2514. I thought you told me it was the mud that you smelt then?—Mud and water.

2515. I presume that you occasionally walk along the banks of the river?—Sometimes.

2516. Have you ever smelt the water from the banks of the river?—Yes.

2517. When did you last smell it so that it was offensive to you?—Very likely you would go two or three weeks, or four or five weeks without smelling it, according to how the wind is.

2518. And then how long do you smell it for?—Till you get away from it.

2519. You have given me a good deal of general information; can you give me approximately any date when you last smelt it in that way?—I do not put these things down, I am obliged to put up with it as I go along. I do not put the dates down.

Re-examined by Mr. BEAUMONT MORICE.

*Mr. C. Faulkner.*
17 Nov. 1882.

2520. You know well enough that you smelt it?—I do.

2521. (*Sir John Coode.*) Were these old reservoirs of which you told us used for the same purpose as the new reservoirs, which you said you assisted in making; that is to say, for the purpose of sluicing the mud from the foreshore?—Yes.

2522. Why were the old reservoirs abandoned, and new ones made?—The land was put out for other purposes.

2523. But they were used for sluicing the mud from the foreshore?—Yes.

The witness withdrew.

Mr. WILLIAM HARLING called, and examined by Mr. BEAUMONT MORICE.

*Mr. W. Harling.*

2524. You live at Erith?—Yes.

2525. And I believe that you have worked at the ballast wharves for about 20 years?—Yes.

2526. Have you had a good deal to do with keeping the place clear of mud?—Yes.

2527. What was the river about there like when you first worked there 20 years ago?—The water was clear, and you could catch plenty of fish there at that time. I have been in fishing boats when they caught a hundred bushels off Erith on a Sunday morning.

2528. (*Sir John Coode.*) Not one boat?—No; 20 or 30 boats lying there.

2529. (*Mr. Beaumont Morice.*) It was a good fishing place?—Yes; there were plenty of shrimps, flounders, and eels.

2530. And whitebait?—Yes, and whitebait.

2531. How long did that continue?—It lasted a long while there, catching the shrimps.

2532. How many years ago did the fishing boats have to go away?—They were there all the summer season catching shrimps; not now.

2533. How many years ago is it that they stopped coming?——

2534. (*Mr. Norman Bazalgette.*) We have admitted the fact over and over again that there are no fish to be caught there.

2535. (*Mr. Lumley Smith.*) The important fact is when they ceased to be there.

2536. (*Mr. Beaumont Morice to the witness.*) When did they stop coming?—About 14 or 15 years ago.

2537. Has there been any alteration in the character of the mud that you have been working in?—There is a lot of filth all along the shore, and the mud "creates" that filth in there in the dock.

2538. When did the mud begin to get that filth?—About 12 or 14 years ago.

2539. Has it got very much worse from time to time lately?—It has got worse lately.

2540. What is it like?—It is a greasy kind of stuff.

2541. Is there any stench with it?—Yes, it all sticks on your finger-nails when you try to wash it off.

2542. What is the stench like?—"Greasified;" and also like your own manure in great lumps all along the sides of the dock as big as your fist.

2543. Lumps of what?—Dung, I call it; closet stuff,—what floats down the river.

2544. You clear the place out where the ships come in?—Yes.

2545. Ships come alongside the wharf and take in ballast?—Yes.

2546. And you have to keep this place clear for them in order to come in?—Yes.

2547. Have you felt any ill effects from this?—Yes, I am under the doctor's hands now; Mr. Jesset is my doctor. Every time I go into that dock I am forced to go to Mr. Jesset, and he allows that it is from the stench from the mud.

2548. Mr. Jesset is the medical officer of Erith, is he not?—Yes.

2549. Do you feel sick?—Always sick and "faintified," and very short-breathed.

2550. (*Sir John Coode.*) For how long has that been the case?—For the last three or four years.

2551. Did you ever suffer in that way before you took to this line of business?—No, nothing in that way at all.

2552. (*Mr. Beaumont Morice.*) Has this state of things, this filth, got worse during the last five years?—Yes, it has got worse. There is a great deal of settlement all along on the steps as you get up the ladders out of the ships.

2553. When the tide goes down, do you find any of this stuff settles there?—Yes, it settles along on the bank.

2554. What is it?—It is black stuff; it is not mud.

2555. Is there any stench from it when it is left there by the tide?—Yes; great lumps of cork and bits of stuff all bound round it. You can squeeze it to pieces and see what it is.

2556. What is the color of that stuff?—Black.

2557. You know the reservoirs for flushing the dock?—Yes.

2558. Have they to be constantly worked now?—Yes, every tide; to wash the mud and filth out.

2559. Do you find that there has been more accumulation of this mud in the dock in the last few years than there used to be?—Yes, and it settles more in the reservoirs.

2560. (*Chairman.*) What dock are you speaking of?—Where the ships come in and lay alongside of the quay, and then there is a reservoir to let the water out and drive the filth out.

2561. You say that every time you go to the dock you suffer. What dock do you mean?

2562. (*Mr. Beaumont Morice.*) What the witness refers to is what we should call a mud berth alongside a staging which is a ballast wharf.

2563. (*Witness.*) Yes.

2564. (*Sir John Coode.*) Is it a basin, or is it a jetty projecting from the shore?—It is not a jetty, it is a gut-way.

2565. It is a creek with a sort of wharf alongside of it?—Yes.

2566. When you speak of the time when you go into the dock, you mean every time you go down for the purpose of clearing away the mud; is that so?—Yes.

2567. (*Mr. Beaumont Morice.*) There is a sort of scooped out basin in the mud in which the vessels lie, it is part of the Erith bight, is it not?—Yes, it is rubbed out from the river side.

2568. There is a lot of mud all round the wharf, is there not?—Yes, and this gut-way is cut through the mud, and then there is a reservoir inside which comes right out and washes the mud out.

2569. But there is no dock wall or anything of that kind?—No.

Cross-examined by Mr. NORMAN BAZALGETTE.

2570. I think you told us that the fishing boats left Erith about 14 or 15 years ago?—Yes.

2571. How do you fix that date?—According to my recollection of the time.

2572. By what circumstances do you happen to recollect so exactly?—Because I used to go off there and have some shrimps off the boats.

2573. You recollect that 14 or 15 years ago you used to go off and have shrimps?—I could not say exactly, but to the best of my judgment it was about that time. I never booked it or anything of that kind.

2574. You know these reservoirs at the ballast wharves?—Yes.

*Mr. W. Harling.*

17 Nov. 1882.

2575. Have they to be very frequently cleared out?—Yes.

2576. What is taken out of them?—Mud and "slurry," black stuff; I cannot say what it is.

2577. The water of the Thames is admitted into these reservoirs, stands in it for a certain time, and then the suspended matter becomes deposited?—It is let off every tide.

2578. How often do you say that they are cleared out?—Every other week, according as the tide suits.

2579. Did you say that every time you go into the dock you have to go and see your doctor?—I have to go and see Mr. Jesset.

2580. Does anybody else work in the dock with you?—One of them does not go to the doctor and one of them does.

2581. Every time you go?—Not every time I go.

2582. Previously to the time when this began, did you enjoy pretty good health?—Yes, as good as I wish to enjoy.

2583. How long has your mate, who has been ill been working at the dock?—He has been working at the dock about six or eight years.

2584. And how long has he been taken in this way?—About two or three years, I suppose.

2585. And previously to that he also enjoyed pretty good health, as far as you know?—Yes, and he is in pretty good health now.

2586. (*Chairman.*) You go to this work about once a fortnight?—Yes, when the tide suits.

2587. (*Mr. Norman Bazalgette.*) Once a fortnight for these last three or four years you have gone regularly to the doctor's?—Yes, pretty nearly every time.

2588. Do you pay the doctor?—I belong to a club.

2589. I presume that you pay the annual subscription to that club and they give you medical advice?—Yes.

2590. Would the books of that club show how often you have been there?—No; only a certificate from the doctor if you lie up; that is all.

2591. You have not been so ill that you have had to lie up?—Only twice.

2592. And what were you laid up from on those two occasions?—The doctor allowed that it was from the stench of the mud.

2593. What did he describe your illness as being?—I do not know.

2594. (*Chairman.*) Is Dr. Jesset here to-day?—No.

2595. (*Mr. Norman Bazalgette.*) Do you remember what the doctor gave you for your illness?—No.

2596. Did he give you anything?—Yes, white stuff in a bottle; that is all that I know.

Re-examined by Mr. Beaumont Morice.

2597. What is the name of your mate?—Clarke.

The witness withdrew.

Mr. Henry Clarke called in; examined by Mr. Beaumont Morice.

*Mr. H. Clarke.*

2598. Do you live at Erith?—Yes.

2599. And have you been working at the ballast wharves there?—Yes.

2600. For how long?—I have been at work for Mr. Parish all my life.

2601. (*Chairman.*) If anything turns upon the health of these people it is the doctor who could tell about it much better than the men themselves.

2602. (*Mr. Beaumont Morice.*) Yes sir, but I have to ask them whether they have had any illness at all.

2603. (*Chairman.*) The doctor will tell us that. However, we will take it very shortly.

2604. (*Mr. Beaumont Morice to the witness.*) You are the mate of Harling?—Yes.

2605. And you occasionally go and work in this mud?—Yes.

2606. (*Chairman.*) Do you find any ill effects from it?—Yes.

2607. What effects have you felt from it?—A nasty, faint, sickness.

2608. Has that been more lately?—Yes; more than when I first went.

2609. What sort of stuff is this mud?—Black, nasty filth, more like the stuff from the human body than anything else, settles on the top.

2610. Is there any stench from it?—Yes.

2611. How often do you go down there?—On spring tides; you cannot go down on ebb tides.

2612. How often have you felt any ill effects from it?—Almost always when we go; and if we do not have our breakfast before we go, we do not want any when we come back.

2613. Has there been any alteration in the character of this stuff in the last few years?—Yes; it gradually "creates" more.

2614. And gets worse?—Yes.

2615. And you say it is not mud, it is filthy stuff?—Yes, it is filth.

2616. Are you under the doctor's hands now?—No, I am not.

2617. When was the last time you went down to this place?—The last springs, about a fortnight ago.

2618. Used you to be laid up from it?—No, I never was laid up through it.

2619. Used you ever to suffer from it till recently?—No, not until lately.

2620. And you say that lately it has got worse?—Yes.

2621. Is there more of this stuff as well as its being worse in kind?—Yes, there is more of it than when I first knew it and took notice of it.

Cross-examined by Mr. Norman Bazalgette.

2622. I suppose you know the reservoirs in the ballast wharves?—Yes, I do.

2623. Can you tell us whether those reservoirs are cleared out more often now than they used to be?—They are.

2624. How much oftener in your time?—When I first started they were not cleared out above two or three times a year.

2625. How long ago is that?—About six years.

2626. How often are they cleared out now?—Once in every fortnight.

2627. The next wharf to your ballast wharf is a dung wharf, is it not?—It is.

2628. What is the process of loading and unloading this dung at that wharf?—I have never done any of it there.

2629. Have you seen it being done?—I have.

2630. Is it loaded and unloaded in very considerable quantities?—Yes, there is a great quantity at times; not always alike.

2631. (*Chairman.*) You have seen them unloading it?—I have seen them as I passed by. I never was amongst it.

2632. You never took any particular notice of it?—No.

2633. (*Mr. Norman Bazalgette.*) It is brought down in barges, and then unloaded and taken away in carts?—Yes.

2634. That is not a particularly pleasant operation, is it, at the next wharf to you?—It is next to it, that is all.

2635. Does it smell nice?—At times; but that

*Mr. H. Clarke.*

17 Nov. 1882.

is not very often because it is not there long at a time.

2636. I presume that at other times it smells nasty?—Yes.

2637. (*Chairman.*) Have you been obliged to go to the doctor?—Yes, I have been and got a bottle of medicine, and, of course, that has put me right again for a while.

2638. How often have you had to do that?—Not very often.

2639. Twice?—Three times or more than that.

2640. That would be four times?—Yes.

2641. (*Sir John Coode.*) Since when?—I suppose the time when I first went to the doctor would be about two years ago.

9642. (*Chairman.*) Did you go to Dr. Jesset?—Yes.

The witness withdrew.

Adjourned to Tuesday next at 1 o'clock.

---

# SIXTH DAY.

## Tuesday, 21st November 1882.

PRESENT:

Sir P. BENSON MAXWELL IN THE CHAIR.

Sir John Coode, Mem. Inst. C.E.
Colonel C. B. Ewart, C.B., R.E.
François de Chaumont, Esq., M.D., F.R.S.
Thomas Stevenson, Esq., M.D.
James Abernethy, Esq., F.R.S.E., Mem. Inst. C.E.
William Pole, Esq., F.R.S., *Secretary.*

Mr. William Gatward called in, and examined by Mr. Beaumont Morice.

*Mr. W. Gatward.*

21 Nov. 1882.

2643. I believe you are a constable stationed at Barking, are you not?—Stationed at Barking Creek.

2644. How long have you been stationed there?—12 years.

2645. How far is the northern outfall from your station?—About 700 yards.

2646. Can you tell us what is the state of the river at your station?—Sometimes it is very bad, especially after a hot day. Then it smells very bad indeed.

2647. In what other way is it very bad besides that?—There is a great quantity of refuse always left on the shore, which smells,—fat, and bullock's lights; and the water is quite black when the sewage is coming out, and after a hot day it smells very bad, you can hardly endure it at all; it makes you feel quite sick.

2648. Have you ever felt any sickness from it?—I have at times, when standing on the wall.

2649. Does this last long, at any time during the day?—During the time that the tide is going down, and after the tide has gone down. The heat of the sun on the mud will produce it.

2650. What sort of stuff is that mud?—Almost black.

2651. Is it mud?—It is greasy, slimy stuff; it looks like mud.

2652. Can you tell from where you are at what time the sewage comes out of the outfall?—Yes; directly they open the sluice I can see it run into the river; directly they lift the slacker.

2653. Can you tell with regard to the time of high water, at what time it comes out?—Yes; I have seen it come out before high water, and I have seen it running up a good deal after low water, after the tide has been flowing.

2654. (*Sir John Coode.*) But do you mean to say that you have seen it running out of the sluice after low water?—Yes.

2655. (*Chairman.*) Sometimes before high water?—Yes.

2656. (*Mr. Beaumont Morice.*) Of course if it is before high water it would go up the river?—It would go up the river then.

2657. Have you seen that on more than one occasion?—On several occasions I have seen it, but I have not the dates.

2658. When you see it after low water do you see it coming out of the sluice from where you are?—Yes, you can see it run right down the gut in the mud into the water; and you can always tell where it is by the colour of the water.

2659. I think at your creek you have a causeway, have you not?—Yes.

2660. What is the state of that causeway on the ebb tide, when the tide has left it?—Sometimes it is very slippery, and there is a great quantity of mud and slime and stuff left on it as the tide goes down.

2661. Is there any smell at all from it?—A very great smell.

2662. What kind of smell?—I do not know that I can explain the smell, but it is a very faint, nasty, sickly smell.

2663. (*Mr. Bidder.*) Is this on the mud?—On the causeway; what is left on the causeway.

2664. (*Mr. Beaumont Morice.*) Is that the causeway at Barking Creek?—Yes, it is a causeway made of wood which runs down to low-water mark.

2665. Have you ever seen any dead bodies taken up?—Yes, I have had the handling of a great quantity of bodies since I have been there at different times. I had the handling of the whole of the "Princess Alice" bodies that were landed at the creek to the number of 34; and at other times I have had bodies that have been picked up of people that have been drowned up the river and have floated down there and been brought ashore by different people.

2666. Will you tell the Commission in what state you found those bodies?—In a most beastly state they were. They had not been in the water above two days some of them; some a little longer; but they smelt so that you could hardly bear it.

2667. Was there any deposit on them?—Yes, amongst the clothing there was a great quantity of slime and filth; and when they had lain a few hours the smell nearly knocked you backwards when you went to them.

2668. Have you ever had to do with bodies out of any other water except the Thames?—No, I never had charge of bodies out of any other water, but I have seen them.

2669. What have you seen?—I never saw any other bodies in the same state as those are that come out of the Thames.

2670. What other ones have you seen?—I have seen some out of the river Lea.

2671. Is that near your place?—No; that was before I went down there, before I was in the police.

2672. And you say that they were in a different state from those which you find in the Thames?—A great deal different; they looked fresher; they would lie for some days in the water and they would not be in the same state as they are in after being a couple of days in the Thames.

2673. Do you know the mud along the foreshore round by Barking?—Yes.

2674. Is there much of it?—Yes; there is a great scope of mud there.

2675. Of what character is it?—The top of it is greenish.

2676. (*Mr. Bidder.*) Will you point out on the map where this place is?—It is there (*pointing it out*). I am stationed within 700 yards below the outfall.

2677. (*Mr. Beaumont Morice.*) Do you know the character of the mud along the foreshore there?—I do not know about the character of it. I know it is very black.

2678. What is it like?—It is almost like filth; it is filth.

2679. (*Mr. Bidder.*) As to the character of the mud, the evidence of chemists will be much more reliable than that of a policeman.

2680. (*Mr. Beaumont Morice.*) I am not asking him as to the character of the mud, but as to its appearance.

2681. (*Witness.*) It is not like other mud that you will find in other places; it is black.

2682. Have you ever had anything to do with any of the fishing in the river?—Yes; I have seen plenty of fish coming there, but they are all dead, or nearly so; they seem in a stupified state. I have seen plenty of eels there. This last week plenty of eels have come down with the fresh water through the rains, and as soon as they get there they lie dead on the stones.

2683. (*Chairman.*) You saw the eels lying dead?—I saw one hundredweight picked up in one morning on the stones at Barking Creek.

2684. (*Mr. Bidder.*) In the creek?—No, not in the creek, but in the river; on the stones along the river shore.

2685. (*Sir John Coode.*) How far from the outfall?—Some would be 700 yards, and some further; some perhaps half a mile down the shore, towards the Horse-shoe corner, getting down towards the southern outfall.

2686. Did you see any near the outfall?—No; the creek runs between me and the outfall. I cannot get up to the outfall.

2687. (*Mr. Beaumont Morice.*) Have you ever seen anything of the kind before?—Plenty of times. About this time of the year, when there are heavy rains, eels come down and they lie half stupefied upon the stones. I have never seen any what you may call live fish there, not but what you could go and pick them up.

2688. Have you ever smelt this sewage smell at any other part besides the exact place where you are stationed?—Yes; I often go down the river in a boat, and sometimes you cannot bear the smell as you go down the river; you are glad to run the boat ashore and get out of it. Sometimes the smell is so bad you cannot stand it.

2689. Is it part of your duty to go up and down the river in a boat?—When I go down the river in a boat I go for my own pleasure.

2690. How far have you gone down the river in a boat?—Down as far as Gravesend.

2691. Have you ever seen any fat on the river?—Yes; you can see that every tide. There are seven men who get their living there pretty well, by skimming the river and getting the fat off it and melting it down.

2692. That you know?—That I know. That is what they called the Thames mud butter.

2693. Do you know how they do it?—Yes; I have been aboard the barge that those men have, and seen them melting the fat down that they got off the river. First of all they have a boat with a well in it, and they fill this boat with fat and let the water into it, and wash it, and all the fat floats on the top and the filth goes out from underneath the bottom of the boat, and it is handed from there into a large tub with reeds and wire put across it, and the steam is turned on, and the steam goes through the fat and melts it. It then comes out in a tub below, and they put a certain quantity of acid with it which causes all the dross out of the fat to go to the bottom, and then the fat is sold for lubricating purposes. They tell me it is made into dripping, but I do not know that myself.

2694. Have you ever seen any solid lumps of sewage floating about?—Yes, I have seen round balls of hard fat floating about, and I have seen great lumps of lights floating about, and other filth.

2695. Have you noticed that at any particular time of the day or the night?—No, there is no particular time; any time when the sewage is coming out.

2696. (*Sir John Coode.*) Do you mean to say that you have seen these lights coming out of the sewer?—No, I have seen them floating in the sewage. I have never been up there at the time; but I have seen them about 300 or 400 yards away from the sewage.

2697. (*Mr. Beaumont Morice.*) Have you seen that often?—Yes; you will see it every tide almost; but you will see it more particularly after a heavy rain.

Cross-examined by Mr. Bidder.

2698. Where exactly are you stationed; are you below Barking Creek or above it?—I am below the outfall.

2699. Then do you sometimes go along the shore to the outfalls?—No, I cannot go along the shore to the outfalls. I go up in a boat sometimes.

2700. For your own amusement?—Yes.

2701. When you have seen the water coming back out of the outfalls, has that been when you have been up there in a boat?—No, it has been when I have been standing on the wall at the creek.

2702. I forget the exact distance of the creek from the outfall?—700 yards.

2703. Hardly so much, is it?—It may not be quite so much, or it may be a little more: I could not say for certain.

2704. Now be careful, if you please. When was it that you saw the sewage coming out before high water?—I could not give you the dates, but it has been during the summer.

2705. Are you certain that you have seen it?—Quite certain.

2706. In the summer of the present year?—Yes.

2707. Once or more?—Several times.

2708. That you are certain of?—Yes. And once since I was up in the office at Cornhill I saw it running up when the tide was running up.

2709. From your station or from the boat?—From where I was stationed. You can always see from the colour of the water the sweep that it takes round in the water. It was on the 25th of August when I saw that. I put that date down. That is this year; since I was up and gave my evidence at the office.

2710. Can you speak to any other day when you have seen it come out before high water?—No, I never took the date at any other time.

2711. When have you seen it running up after the tide had turned?—That was on the 25th of August.

2712. Do not let us confuse different things. You have said two things; you have said that you have seen the sewage let out before high water; that is one thing; and you have also said you have seen the sewage running up after the tide had turned to the flood?—Yes.

2713. I ask you first when you have seen the sewage let out before high water?—And I say I cannot give the date.

2714. I understand that it was on the 25th of August that you saw it running up after low water?—Yes, after low water—about half flood tide.

2715. Where were you?—Standing on the wall.

2716. Your own wall?—Yes, against the manure factory.

*Mr. W. Gatward.*

21 Nov. 1882.

2717. You were a long way off; how did you see it there; by the colour of the stream?—You could see by the colour of the stream where the sewage was running out. You see it rush out of the outlet into the river, and you can see the tide sweep it up or down.

2718. But you say that you are 700 yards off?—It is about 700 yards altogether from me to the outlet.

2719. It would be going away from you; it would not be passing you?—It would be going up towards Beckton.

2720. And you say that at a distance of about half a mile you can see the sewage in the river and distinguish it from the other water?—Yes, quite plain.

2721. Half a mile off when it is going in the opposite direction?—Yes, quite plain.

2722. How far up the river did you trace it in that direction?—You can see it run up very near as far as Beckton Pier; you can see the different colour in the water.

2723. From your station?—Yes.

2724. How far is that?—Perhaps three quarters of a mile.

2725. Have you any other date on which you have seen the sewage running up after the tide had turned?—No, I never put down any date. I was not aware that I should be called on this job or else I should have done it plenty of times.

2726. What is your particular duty when stationed on that river wall?—My duty is to be there when I am wanted. I have no particular set time.

2727. Have you a beat?—No, I have no beat. There is a little village there of about 60 or 70 houses, and I am stationed there to keep peace and quietness, if I can. Only once a day I go to Barking.

2728. I understand you to say that your observations of the smell in the river have been principally when you have been in a boat for your amusement?—Or standing on the wall. Sometimes if you stand on the wall you can hardly bear it.

2729. The wall that you speak of is just below Barking Creek, is it?—The river runs round it; it is part of the wall that keeps the Creek in its place.

2730. There is no other smell that is at all offensive in that neighbourhood except the sewage?—Yes there is. Some of the factories are very offensive; but it is quite different from the other smell. What you smell from the factories is more sulphureous.

2731. And I understand you to say that you have traced the smell going down the river in a boat for your pleasure?—Yes I have sometimes, as low as Gravesend.

2732. Is it your custom then to go in a boat for your pleasure?—Yes, sometimes.

2733. Rowing, sailing and bathing?—Sailing. I should not like to bathe in it.

2734. Do you know Barking Creek itself?—Yes.

2735. Does a good deal of sewage go down Barking Creek?—There is some turned in at the Town quay.

2736. Is that mud up the Barking Creek rather nasty?—The higher you get up the creek the better it is.

2737. But below Barking is it nasty?—No, not so bad as it is in the river.

2738. But is it bad?—Sometimes.

2739. Is it black?—No, it is not. It is more of a yellow colour.

2740. (*Sir John Coode.*) Does all the sewage of Barking come into this creek?—I believe it does.

2741. About what is the population of Barking?—I should think about 15,000.

2742. (*Mr. Bidder.*) It is a small creek, is it not?—It is about as big a creek as there is on the river Thames; it is not very long.

2743. What is the width of it?—I should think it is 50 to 60 yards across.

2744. Is that at high water?—Yes, at low water there is very little water; you can walk across it at low water.

2745. Have you heard complaints about the smell in the creek?—I have, from the people living at the creek.

2746. They say it is very bad at times?—It is very bad at times.

2747. You know that yourself?—I do.

2748. I suppose you do not know what sewage comes into it above Barking?—I know nothing of my own knowledge, only what I have been told. I have been told that there is none; they have cesspools.

2749. You are quite right in limiting yourself to your own knowledge. I want to fix the position of this causeway exactly, on which you say you have detected a bad smell. You said there was a causeway in Barking Creek where you smelt a bad smell?—It runs into the river; it is not in Barking Creek.

2750. Is it at the corner?—Yes.

2751. Is it on the east or the west side of the creek?—On the east side.

2752. Your side?—Yes.

2753. It is just where the creek comes into the river?—Yes, it is just where the entrance is.

2754. And you have noticed a bad smell there?—Yes.

2755. It is where Lawes' chemical works are?—Yes.

2756. (*Sir John Coode.*) What is about the length of this causeway; it is not a very long affair, is it?—It is about 20 yards long, I suppose. It runs from the wall down to low-water mark.

2757. Towards low-water mark, I suppose, not to low-water mark?—It goes right to low-water mark.

2758. Is the foreshore only 60 yards broad there?—I could not say exactly; but I should not think it is more than that. It runs alongside the jetty.

2759. (*Mr. Bidder.*) Now about one or two other matters that you have spoken about, bullocks' lights for instance, they would be large masses of flesh, I suppose?—Yes, large lumps of lights.

2760. How big?—I dare say as big as my head.

2761. Have you ever seen them come out of the outfall?—No, I cannot say that I have seen them come out of the outfall.

2762. Now about the bodies. The bodies that you speak of, I understand, are principally those that were taken up of people that were drowned when the "Princess Alice" was sunk?—Yes, that was when I had the most; but I have had plenty of others.

2763. Where were they landed?—They were landed at the creek, thirty-four of them.

2764. They had been dragged for, I suppose?—Some floated.

2765. Were some of them found close to the outfall?—No, I do not think they were; they were picked up between the outfall and the creek, those that were landed there that night. The others were most of them picked up on the other side of the river and brought there.

2766. At any rate several of them were picked up between the outfall and the creek?—Yes; I picked up two myself there.

2767. Were they covered more or less with that mud which you see upon the shore?—All their clothes were; and in the morning they were quite black.

2768. Were some of them found on the shore?—I believe so.

2769. Were you very much surprised at their being covered with the mud on the shore?—I was very much surprised at the state the bodies were in, the way they went.

2770. Will you answer my question. Were you surprised at their being covered with the mud on the shore?—Yes, I was.

2771. Having been picked up on the mud. I think inquests were held upon those bodies?—Yes.

2772. Were they seen by medical men?—No, I do not think they were.

2773. Was no medical man called in?—No.

2774. Are you quite sure?—Quite sure.

2775. (*Sir John Coode.*) I do not think you need

follow that. The coroner sat on the bodies, and then adjourned the inquest afterwards to Woolwich, so that they were all sat on together at Woolwich.

2776. (*Mr. Bidder to the witness.*) But you mean to say that no medical man ever saw any of those bodies?—Not those that were brought on shore dead.

2777. (*Mr. Beaumont Morice.*) I think that was so with regard to the bodies; they were all brought over to Woolwich. I happened to be at the inquest and I know that that was the fact.

2778. (*Sir John Coode.*) I take it that the witness means that no medical man saw the bodies at Barking.

2779. (*Mr. Bidder to the witness.*) Were the bodies taken to Woolwich?—Yes.

2780. Who saw them at Woolwich you do not know?—No, I do not know anything about that.

2781. About the eels: where was it that you saw the eels picked up?—Along the shore.

2782. Above Barking Creek or below, or in the creek?—Below the creek.

2783. (*Chairman.*) You said between the two outfalls?—Yes.

2784. (*Mr. Bidder.*) Were any of them picked up in the creek?—No, I do not know of one.

2785. Are you quite sure?—Yes.

2786. What size are those eels?—Some of them would be as long as my arm.

2787. (*Mr. Michael.*) And how thick?—Perhaps as thick round as the bottom of my thumb, weighing about 2 lbs. and some of them as much as 3½ lbs.

2788. When was this?—Last week and the week before.

2789. Is it a common thing to get quantities of eels in that neighbourhood?—Yes, about this time of the year.

2790. Do you happen to know whether there are some paper mills up Barking Creek?—Yes, there is up the river Roding at Ilford.

2791. The river Roding runs into the creek?—Yes.

2792. Are those paper mills in a large way of business?—I think they are.

2793. Do they discharge refuse matter into the creek?—They did at one time, but I believe they do not do so now. There has been a great bother about it.

2794. Do you know the Beckton Gasworks?—Yes, I do.

2795. Have you ever been on that part of the river?—Yes, pretty often.

2796. Have you ever seen any discharge coming from them?—I have seen little pieces dropping out of the pipes after they have loaded a barge with tar; that is all.

2797. Have you never seen any strong smelling discharge coming from them?—No.

2798. Have you ever seen a sewer at the Beckton Gasworks discharging into the river?—No.

2799. Do you know whether there is a sewer there?—I do not.

Re-examined by Mr. Beaumont Morice.

2800. You do not know what there is at Beckton?—No, I do not.

2801. You have been asked about these dead bodies; it is perfectly clear that when they came before you they were drowned, so far as you could see?

2802. (*Mr. Bidder.*) That I will admit.

2803. (*Mr. Beaumont Morice.*) You have been asking the cause of death, that is why I asked the witness the question. (*To the witness.*) As to their being covered with mud, was the mud that they were covered with like what was on the shore?—Just the same.

2804. What sort of stuff was it?—Black slimy stuff.

2805. Was there any difference between the bodies that were brought over from the other side of the river and those on your side?—They had been in the water longer, so that they would be in a worse state.

2806. But as to their being covered with anything like mud, was there any difference?—No; there was no difference.

2807. (*Sir John Coode.*) Do you mean to say that bodies were taken from the other side of the river to Barking?—Yes.

2808. I thought you said that they were taken over from Barking to Woolwich?—Yes, they were first brought to Barking. Thirty-four we had at Barking Creek.

2809. How many were brought from the opposite side of the river?—I could not say exactly; but there may have been ten or fourteen.

2810. Have you any personal knowledge of any other part of the Thames?—No.

2811. You cannot speak as to the comparative condition of those bodies, and of bodies washed ashore in the other parts of the Thames?—No.

2812. (*Mr. Beaumont Morice.*) With regard to the stuff that was found on them, was it found on their bodies or mixed up with their clothing?—Mixed up with their clothing and flesh. You had to take a mop to get it off.

2813. You know the factories; are you clear that the smell from them is different from that of the sewage?—Quite different altogether.

2814. How is it that you can tell the sewage when you see it coming along the river, going up with the flood?—By the colour of the water and the bits of filth that you see floating about on it.

2815. Anything else?—And the smell.

2816. You were asked how far it was off you; would not the flood tide set in rather towards Barking Creek in coming up?—No: it will set off from Barking Creek in coming up.

2817. (*Mr. Michael.*) The other side of the creek?—The other side of the creek.

2818. (*Mr. Beaumont Morice.*) How far would it be off you?—It would be about 700 yards.

2819. (*Chairman.*) You stand upon your wall, as I understand, 700 yards from the outfall, and as the tide rises you say you see the sewage actually come out of the outfall and go up the river?—That is right.

2820. (*Mr. Beaumont Morice.*) And you can see it perfectly from where you are?—Yes, I can see it as perfectly as I can see you.

The witness withdrew.

George Roberts called in, and examined by Mr. Beaumont Morice.

2821. I believe you are an inspector of the Thames Police, stationed off Erith?—Yes.

2822. How long have you known the river Thames?—I have known the river Thames from 30 to 40 years.

2823. How long have you been stationed at Erith?—Just over four years; 4½ years now.

2824. Do you remember the outfalls being made?—Yes.

2825. Can you tell us what was the state of the river before that?—The river was in a very good state, so far as the water was concerned.

2826. (*Sir John Coode.*) Where were you when the outfall was made, because you have been only at Erith for four years?—In the same service that I am now.

2827. But in what district?—I was in the Blackwall district at that time.

2828. Did the portion of the river on which this outfall is situated fall within this district at the time when it was made?—No, not the southern outfall; the northern outfall did.

2829. How long had you known that part of the river before the northern outfall was opened?—20 years previously to that or nearly so.

2830. (*Chairman.*) You are now an inspector of of the Thames police?—Yes.

*G. Roberts.*
21 Nov. 1882.

2831. How long have you been an inspector?—About 13 to 14 years.

2832. Have you during all that time been quartered in the lower part of the river?—No, I have been all over the river. I have been up this way towards Putney.

2833. Then before these 13 or 14 years what were you?—I was a constable.

2834. When did you enter the service?—I entered the service in the early part of 1860.

2835. Then from 1860 to the present time you have been on the Thames as a constable or inspector?—Yes. I was, previously to that, on the Thames in the Customs service.

2836. (*Sir John Coode*). Did your duties as a custom-house officer call you frequently over this part of the river?—Yes, I was in that district. Our station was from Woolwich to Gravesend, or Northfleet, just above Gravesend.

2837. (*Dr. de Chaumont.*) How long were you in the Customs before that?—I could not say the exact time; but from 12 to 18 months I should think. I have not the particulars with me as to that, but it was over 12 months.

2838. And your knowledge of the Thames extends from 12 months before 1860?—I have been on the Thames from my boyhood.

2839. In what capacity?—In the first place I was a boy in a hatch-boat bringing fish to Billingsgate Market from the fishing smacks.

2840. Then you have known the Thames all your life?—Yes; I have known it for a great many years.

2841. (*Mr. Beaumont Morice.*) You knew it before the outfalls were made, and you have known it since?—Yes.

2842. Has there been any difference since the outfalls were made?—As regards the water, the water has been very bad since.

2843. In what way?—Such bad smells emanating from it.

2844. Do you smell those bad smells at any particular time?—Yes; I have noticed them most particularly when the water is still, in hot weather; and I have noticed the smell very bad in close foggy weather when the water has been still and quiet.

2845. Have you ever suffered from any sickness yourself?—I have not exactly been laid up, but I have felt very sick at times when I have been about the sterns of steamers, as I have been occasionally, sometimes sailing and sometimes rowing; and sometimes when the water was very still I have felt very sick.

2846. A sort of sickness you say?—Yes, I have never been laid up.

2847. I believe you live on the shore; you do not live on the boat, do you?—No, I live nearly a mile up inland.

2848. And I take it that it is when you are afloat that you experience this smell?—Yes.

2849. Have you ever seen any dead bodies taken out of the river?—Yes, I have seen several; not many since the "Princess Alice" disaster.

2850. You saw some then?—Yes.

2851. Will you tell the Commission what state they were in?—They were terribly swelled, and in a decomposed state after being a very short time in the water. I think there were as many as 24 lying at Erith in the engine house.

2852. (*Sir John Coode.*) How long was that after the disaster?—Some two or three days.

2853. You are sure it was not more?—I could not say positively to a day, but I know that it was very closely afterwards.

2854. (*Mr. Bidder.*) What was the date?—In September I think it was; the early part of September.

2855. (*Mr. Michael.*) I think it was the 2nd of September.

2856. (*Mr. Beaumont Morice.*) Was there any mud or anything else on them?—That I did not notice. I could not say.

2857. Have you noticed the mud about the ore-shore away down the river above Erith?—Yes.

2858. Do you know that part well?—Yes, well; I am up and down every day.

2859. Will you tell us what the mud is like up and down there?—It looks terribly black and dirty, and smells very badly at times, when there is a wash on the shore stirring it up.

2860. How far does that extend up the river from, say Erith?—It goes right up to the extreme of my district. My district goes to just up above the northern outfall, and it extends right up to the upper part of my district.

2861. (*Chairman.*) This black stuff extends up to the upper part of your district?—Yes.

2862. (*Mr. Beaumont Morice.*) From what part?—Say from Dartford Creek.

2863. Up past Erith, as far as the northern outfall?—Yes; but it is not so bad these last few months. These last two or three months the mud has gone away much off the shore.

2864. Why is that?—For the reason that it is drawn off the shore; it does not lie so thickly on the shore as it did.

2865. (*Chairman.*) Since when is that?—I should think it is three months since first I noticed it. It seems to be drawing more off the shore.

2866. (*Mr. Bidder.*) What part of the shore are you speaking of?—The river shore.

2867. (*Mr. Beaumont Morice.*) You say that it is black stuff; does it smell badly?—It does. A steamboat makes it smell badly when it is stirring it up.

2668. Has there been any alteration either in the quantity of it or in the smell of it during the last few years?—It has seemed to accumulate during these last few years until very recently, and now it seems to be drawing off the shore into the channel again, or going somewhere else.

2869. What part of the shore are you speaking of?—I might say from Erith very nearly up to Barking.

2870. That is to say about the limit of your district?—Yes.

2871. I take it that you know the south shore all up through Erith Bight?—Yes.

2872. Does the same thing hold there as well?—Yes, just the same; but still it is drawing off.

2873. Have you ever used the water for any purposes on board the boat?—We used to do so when I was in the Customs service frequently; in fact, at low water time we always used to dip our water; but we cannot do so now.

2874. Why cannot you use it now?—Because it is so bad.

2875. (*Mr. Bidder.*) The other day we thought we should shorten the proceedings on this matter by agreeing as to this.

2876. (*Mr. Beaumont Morice.*) I do not wish to take the witness through the fact that he did do it before and that he does not do it now; but I think I may ask the question why he does not do it now.

2877. (*Witness.*) It is so bad that we cannot use it for washing purposes or cooking, it smells so.

2878. (*Chairman.*) How do you mean that it is so bad?—It is so dirty and smells so.

2879. You do not use the water for washing or for drinking now, because it is so dirty?—Yes.

2880. (*Sir John Coode.*) What is the furthest point down the river at which you ever took the water for washing or drinking when you were in the habit of taking it for those purposes?—Very seldom below Erith on account of its being brackish.

2881. Have you taken it as far down as Erith?—Yes, many times.

2882. Have you found it quite fresh?—Yes, we have found it suitable for washing and cooking and all that sort of thing.

2883. (*Mr. Bidder.*) And for drinking?—No, I do not know that we have ever taken it there for drinking.

2884. (*Sir John Coode.*) How far down have you taken it for drinking?—We have taken it at Woolwich.

2885. Is that the farthest point down that you think it was ever taken for drinking purposes?—I cannot say that, but I think it is the furthest down that I ever had any for drinking purposes, in fact I think at the time when the smacks were there they used to dip their water at Barking Creek. I have heard the old fishermen talk about dipping there.

2886 (*Mr. Beaumont Morice.*) Why did you not dip lower down; say at Erith?—The water is brackish there.

2887. Have you ever noticed at what time the sewage is discharged from the outfalls?—Yes, I was directed to keep observation on the 1st of August 1880, I think, or to have observation kept, in order to ascertain whether it was running into the Thames on the ebb or flood.

2888. (*Chairman.*) Did you notice it?—Yes. On the 1st of August I posted a man at 9.30 a.m. on the bank at Crossness, and it was running freely into the Thames at that time and going up the river.

2889. Did you see it running into the Thames?—Yes, at 9.30 a.m.

2890. (*Sir John Coode.*) Did you notice the state of the tide at that time?—Yes, it was high water that day at 9.53 a.m. at London Bridge.

2891. (*Mr. Bidder.*) What time would it be high water at Barking?—There would be nearly half an hour's difference, so far as regards the flowing on the shore; but then the stream of tide would run up after that. I went on to the northern outfall at Barking, and at 10 o'clock, when I reached there, it was flowing into the Thames and going right up the river. On the 2nd of August it commenced running at 11.20 from the southern outfall.

2892. (*Chairman.*) Did you see it?—No, I cannot say that I did on that occasion. I posted a man there at the same time as the day previous, and it did not run so soon. The man reported to me when I took him into the boat, that it commenced running at 11.20. I did not see that myself; that was reported to me by the man that I placed there for the purpose. I went then myself to the northern outfall and it commenced running there at 11.15.

2893. (*Mr. Bidder.*) When was it high water on that day?—At 11.12 at London Bridge.

2894. That would be 10.40 at the outfall?—It would be later than that.

2895. (*Mr. Beaumont Morice.*) At what time would it be high water down at Barking?—There would be about half an hour's difference between Barking and London Bridge; 40 minutes to Erith, and 60 minutes to Gravesend.

2896. That is on shore, is it not?—Yes, that is the rise of the tide. The stream runs up after it is high water on the shore.

2897. You took it again on the 3rd, did you not?—Yes, I placed a man there at the same time at the southern outfall; and it commenced running there at 12.45, and at the northern outfall at 12.15; high-water at London Bridge being that day at 12.18.

2898. Now what was done on the 4th?—On the 4th there was only observation kept at the southern outfall, and the discharge commenced at 1.5. I have omitted putting the time of high water down on that day, but it would be somewhere about the time or a little before that, I should think, at London Bridge on that day.

2899. (*Sir John Coode.*) Is this all in 1880?—Yes; on the 1st, 2nd, 3rd, and 4th of August 1880.

2900. Have you any since that date?—No; that is the only time that I have been directed to keep any observation.

2901. (*Mr. Beaumont Morice.*) You watched it on four consecutive days?—Yes.

2902. Have you ever on any other occasion noticed at what time the sewage comes out, without being set to do it?—Yes, I have often seen it come out on the flood tide; but not recently.

2903. Of course if it comes out on the flood tide it goes up the river?—Yes; I have seen it a long way above the outfall.

2904. How far have you seen it above the outfall?—I have seen it above Woolwich and the water quite black.

2905. (*Sir John Coode.*) Have you traced this black water flowing all the way from Erith up to Woolwich?—Yes, right up the tideway.

2906. You have followed it up?—I have not exactly gone for that purpose; but I have seen it on my rounds. I have seen the black water going up with the sets of the tide.

2907. (*Mr. Beaumont Morice.*) Have you ever gone down the river to see how far it has gone down?—I do occasionally go down as far as Gravesend, but I never take much notice below what I call my own limits, that is to say below Dartford Creek.

2908. Have you ever noticed any lumps of stuff in the sewage?—I have seen quantities of round balls and the likes of that, lying about on the stones on the shore—greasy stuff, all up and down on either side of the river banks.

2909. In any particular part of the river?—I think in Half-way Reach. I have seen it more than anywhere, and by Cold Harbour Point I have seen a great deal of it.

2910. Is there much fat in the river at this time?—I have seen but very little about lately, but in the bays and in the slack water there is frequently lots of it and lots of slaughter-house refuse, such as sheeps lights, and all manner of filth of that description, floating about.

2911. I believe you have some men under you?—Yes.

2912. Have any of those men ever suffered from illness?—Yes; one man was suffering from diarrhœa. He was returned sick on the 6th of July and on the 6th, 7th, 8th, and 9th he was suffering from diarrhœa.

2913. (*Mr. Bidder.*) This is going too far, because it can only be mere hearsay, and what the cause of his diarrhœa was we cannot tell.

2914. (*Chairman.*) It may be the foundation of some valuable evidence, but at present it does not go very far.

2915. (*Mr. Bidder to the witness.*) This man reported to you that he was suffering from diarrhœa, and you gave him leave of absence?—Yes, he was reported by the doctor as "suffering from diarrhœa, "probably caused by bad smell on the river."

2916. Who was the doctor?—Dr. Jesset, the divisional doctor. I copied this from his entry in the sick book.

2917. (*Chairman.*) Was it one man?—Yes.

2918. What is his name?—Hogben.

2919. Was that this year?—Yes.

2920. (*Sir John Coode.*) How many men have you under you?—Four.

Examined by Mr. Lumley Smith.

2921. As I understand it you put the time of high water at London Bridge on one of these occasions at 11.12?—Yes.

2922. You say that high water at Barking is about half an hour earlier?—Yes.

2923. I understand you to say that you are speaking of the time when the water comes to its highest point adjoining the bank?—Yes.

2924. Does the stream continue to flow up past Barking after it has reached the highest point on the bank?—Yes; sometime afterwards, a quarter of an hour or 20 minutes, or sometimes half an hour.

2925. Then would sewage which was discharged at the time when the water has reached its highest point at the bank, still go up the river?—Yes.

Cross-examined by Mr. Michael.

2926. Are you perfectly clear about that? Is it not a fact that the stream runs down for half an hour before high water, by the side of the shore?—Yes, that is quite true.

2927. Therefore any sewage coming into the stream would be carried down, and not carried up?—It is carried down a certain distance and then it meets the up tide, up at the point, at Barking.

*G. Roberts.*
21 Nov. 1882.

2928. Would you kindly tell me who gave you the direction in 1880 to make these observations?—My superintendent came down and left a memorandum in the book; I suppose it would be the Commissioners order. I do not know who else it would come from. I was called upon to report upon the 5th.

2929. (*Chairman.*) What is the superintendent's name?—Superintendent Alston. He made an order in my book for me to keep observation.

2930. (*Mr. Michael.*) Does the paper which you have there contain the whole of the memoranda which you made in accordance with that order?—No; that is simply just to refresh my own memory.

2931. Where are all the rest of the memoranda?—What memoranda do you mean?

2932. You have taken this out from some memoranda, I suppose?—Yes.

2933. Where are the other memoranda?—On board of my vessel.

2934. How is it that you took this out and left the remainder behind?—I simply wanted it to refresh my memory.

2935. Did you consider this the most important portion of all the observations that you made?—I thought so.

2936. How long were you about the matter altogether?—Four days. Superintendent Alston came down on the 31st of July, and he directed me to keep observation or to have observation kept, for a few days, and I was to send in a report upon the 5th. Consequently on the morning of the 5th I sent in my report, and that is what I sent in.

2937. But I cannot make that agree with what you have given us, because you have one memorandum here, "Bad smell on the river on the 2nd and 30th of July"?—That is another thing.

2938. How long did all these observations extend from which you have extracted "Bad smell on the "river 2nd and 30th of July"?—That was this year. We had two very still hot days; I suppose they were two of the hottest days we had, and the river on those two occasions smelt very badly; and I made a note of that in case I should be asked the question.

2939. (*Sir John Coode.*) Is that a copy of what you sent to the superintendent, or did you send him a full copy of the notes that you had in your book?—I sent him a full copy.

2940. (*Chairman.*) You made a report in writing, I suppose, to the superintendent?—Yes.

2941. Is not that writing here?—No.

2942. You could bring it, I suppose, or the superintendent could bring it?—My books could be produced.

2943. You say that you made the report in writing; did you enter it in your book?—Yes.

2944. It was not addressed in the form of a letter to the superintendent; it was written in your own book?—It was written in the book and then a copy was sent to the superintendent.

2945. The superintendent ordered you to make a report?—Yes.

2946. And you made a report?—Yes.

2947. And that report was in writing?—Yes.

2948. And it was addressed to the superintendent?—Yes.

2949. So that the superintendent would probably have it then?—I should think he would forward it on to the Commissioners; I do not know.

2950. (*Mr. Michael.*) Did the report only extend over these four days, the 1st, 2nd, 3rd, and 4th of August?—That is all.

2951. Then anything that appears on this bit of paper beyond that is something that you put down yourself?—That is it.

2952. And you did not take any other observations, save on those four days, except what you have casually made a note of here?—That is it.

2953. What, for the last four years, has been the extent of the beat that you have specially to attend to?—Between Dartford Creek and Beckton; that is just above the northern outfall.

2954. Then you have nothing to do with Erith?—Yes.

2955. Are you on the river all day long?—Not all day.

2956. How many hours?—Sometimes I am out on a morning, sometimes in the evening, sometimes in the middle of the day, and sometimes at night.

2957. Have you the four men with you at the same time; do they live on the river?—Yes, three out of four live on board the vessel. I have one married man who lives on shore.

2958. Where is that vessel moored?—Right off Erith pier, or nearly opposite the pier.

2959. What is the name of the married man?—Mastin.

2960. How many other men belonging to the police live on board the vessel?—Three single men.

2961. Are those the only three river police living on the river in that section?—Yes.

2962. Then do any of the other police live on the river in boats in any of the other sections?—No, not below the Blackwall station.

2963. Then from Blackwall down to Dartford there is only one station for the river police, and they live on the river, is that so?—The Blackwall station extends down to Barking, and I go up and meet them at Barking Creek.

2964. Are there any other stations of the river police?—Not below mine, my station is the lowest.

2965. With regard to this bad smell on the 2nd and 30th of July, that was on the river itself?—Yes.

2966. What kind of smell was it?—A nasty, filthy, smell like rotten soap suds. I could hardly describe the smell.

2967. Where did you smell it?—In Barking Creek I smelt it very badly, and so I did in Half-way Reach.

2968. That was in the river itself, of course?—Yes.

2969. Have you ever smelt that smell on the land anywhere?—No, I never noticed the smell on the land.

2970. How many years have you been on the river?—Very nearly 40 years.

2971. On this portion of the river?—This last time I have been here, now, about 4½ years.

2972. When did you first notice that the deposit of mud was diminishing from Erith and up along the banks of the river?—I should think it is two to three months ago; I could not say exactly how long.

2973. Is the diminution large?—Yes, it seems to have gone away considerably.

2974. At Erith itself?—Yes, at Erith and at other places up along the river shore.

2975. What is the colour of the mud there?—It is a sort of bluish brown.

2976. Is it different in colour from the mud which you observe on the banks of the river in other portions?—It is very different from what it is further down.

2977. How far down?—Say below Greenhithe; from Greenhithe to Gravesend, or below Gravesend.

2978. How far up does this mud of this bluish brown colour extend?—Up into Gallion's Reach, whether or no.

2979. Do you know Barking Creek?—Yes.

2980. What is the colour of the mud there?—It is very seldom that I go up the creek; I pass the creek's mouth.

2981. What is the colour of the mud at the mouth of the creek?—It is about the same. It is a darker colour there.

2982. A bluish brown?—Yes, a darker colour.

2983. Throughout the extent of your beat does it remain of the same colour all the way up?—I do not see much difference in it.

2984. Then may I take it that from Blackwall to Dartford this mud extends the whole way?—From Beckton just about the same.

2985. Is it the same on both sides of the river?—I do not think there is much difference.

2986. Where is it that the mud has been extending during the last three or four months?—It is drawing off into the bed of the river I should imagine.

2987. That is imagination on your part; you do not know that it is in the bed of the river?—No; the only reason I go by is that when I am rowing my boat up along the shore at low water time we can feel the mud a long way off, 20 or 30 yards.

2988. Do you mean that you can perceive the smell of it?—No, we can feel it with the oars.

2989. Do you see any dredging operations going on in the river?—Yes, there are some in Long Reach.

2990. What is the character of the material that is brought up by those dredging operations?—Principally ballast and gravel, I think. That is some distance down below Erith, a mile and a half or two miles.

2991. You have had four men under your orders for the last four years?—Yes.

2992. How many days have those four men been off duty during the whole of that time?—I could not tell you unless I had my sick book. They are something like myself; they are pretty strong, and they are not very sickly.

2993. (*Mr. Bidder.*) We may take you as a fair sample?—Yes, I think you might.

Re-examined by Mr. Beaumont Morice.

2994. You say the oars touch the mud coming up; that is some distance from the shore, is it not?—Yes; I noticed that on Sunday last particularly, at low water.

2995. So that you find it becoming shallower farther from the shore than it used to be?—Yes; it seems to me as if the mud was drawing off from the shore, from inside low-water mark to the outside of it.

2996. Do you think that the amount of rain and fresh water coming down the river has anything to do with that?—I have noticed that when the water has been very bad, if we have had a shower of rain or a breeze of wind, it seemed to sweeten the water somewhat.

2997. With regard to the gravel that you said was taken up at Long Reach, that is a straight reach, is it not?—Yes.

2998. You often have freshets down the river, do you not, at this time of the year?—Yes, we have had the fresh water extending down that far.

2999. Do you notice any difference either in the water itself or in the banks, after freshets?—I cannot say that I have taken that particular notice; but we can always tell by the colour of the water when the freshets are down.

The witness withdrew.

Mr. Edward Arundel Carttar called in; examined by Mr. Beaumont Morice.

3000. I believe you are one of the coroners for the county of Kent?—I am.

3001. Will you tell the Commission the extent of your district?—My district extends from Rotherhithe to Gravesend, mid-stream.

3002. Where do you reside?—At Greenwich. My district also extends to the north side of mid-stream, in the parish of Woolwich.

3003. That part of the parish of Woolwich which was in the county of Essex?—Yes.

3004. I think you have been coroner for about two years?—Two-and-a-half years.

3005. And your father was, I think, coroner for something like 50 years?—He was.

3006. And I believe during part of the time you assisted him in his duties, did you not?—No, I did not.

3007. (*Mr. Bidder.*) Is the office of coroner hereditary in Kent, then?—Not quite.

3008. (*Mr. Beaumont Morice.*) During the time that you have been coroner how many inquests have you held?—Over 800.

3009. How many of those have been on bodies taken from the river?—I made a calculation last night, and on reckoning it up I found that about 98 were out of the river Thames; about 156 altogether out of water.

3010. (*Sir John Coode.*) Over what other water does your district extend besides the Thames?—The river Ravensbourne and the river Darent; and then I have the Grand Surrey Canal, and ponds and ditches, wells, baths, butts, pails, docks, and so forth. I have jurisdiction in 11 parishes that abut on the river, and I have had 98 inquests on bodies taken from the Thames.

3011. I believe that in last year, 1881, you had 32 inquests on bodies recovered from the river Thames?—I had.

3012. Can you tell us, without any trouble, what parts of the river they were taken from, or where you held the inquests?—Yes. I am supposed to hold them in the parishes where they are found. There were two in the parish of St. Paul, Deptford, one in St. Nicholas, Deptford, 14 in Greenwich, four in Charlton, nine in Woolwich, and two in Erith; that is 32 altogether.

3013. What has been the condition of those bodies that have been taken out of the river?—There is a marked contrast between them and those that I have had before me which have been taken out of other water—fresh water, out of the river Ravensbourne, and the river Darent, and out of canals and ponds, and ditches, and wells.

3014. What is the contrast?—In the one case, that is to say, in the case of bodies taken from the Thames, they are very much discoloured and disfigured, by the gas, I presume. They turn, at various stages, from pink to white, and green, and blue to black, and the decomposition is very rapid in summer in the case of those that come from the Thames, particularly below Charlton. Two or three days is sufficient.

3015. Is there any deposit of any kind upon the bodies?—Very often, of mud and filth, and there are complaints about it.

3016. (*Sir John Coode.*) That would be the case in every muddy river, would it not?—It would.

3017. The question is as to the kind of deposit?—In some cases we have sand in the pockets, and so on.

3018. Whatever the prevailing matter may be on the shore of the river is found accumulated about the clothes and the bodies. The kind of matter is under consideration in this case?—It is very offensive to the smell; that is all I can say. I am not a chemist.

3019. And more so with these bodies recovered from the Thames than with those recovered from the other waters with which you have to deal?—Very much more so.

3020. (*Mr. Beaumont Morice.*) Is there or is there not a marked difference between what you get from the Thames and what you get from any of these other rivers?—There is a very marked difference.

3021. (*Chairman.*) In what condition do you find the bodies that are taken from the Surrey Canal and from the docks?—They are comparatively clean.

3022. You do not find any mud or any offensive matter about them?—A little, but a very little, in the Grand Surrey Canal.

3023. (*Dr. Stevenson.*) Can you speak as to mud being found upon the bodies from the docks?—Yes; I have the Albert Dock in my district at North Woolwich.

3024. Do you find mud on bodies that are taken from the docks?—Slightly.

3025. Is that offensive?—I have not noticed it.

3026. (*Mr. Beaumont Morice.*) Will you tell us in what particular parts of the river you find that the

*Mr. E. A. Carttar.*

21 Nov. 1882.

bodies come out worst?—Further down my district, as a rule, I think.

3027. What do you call further down?—Below Charlton down to Erith.

3028. (*Sir John Coode.*) Will you kindly tell us between what points?—Between Charlton and Gravesend. There is a contrast between that and up the river to Rotherhithe.

3029 (*Chairman.*) From Charlton to Erith is the worst?—Yes, decidedly so.

3030. (*Mr. Beaumont Morice.*) How long have you known the river itself altogether?—About 26 years, I should reckon, as long as I can remember.

3031. Can you tell us (not from your official knowledge, of course) what in the early part of that time was the state of the river?—It has greatly improved of recent years.

3032. In what part of the river?—At Greenwich particularly, and higher up.

3033. With regard to the river below Greenwich, what do you say?—It has become worse, I think.

3034. I think you held an inquest as lately as the 24th of July, did you not, in the neighbourhood of Erith?—Yes, I think it was on the 24th of July; on a Monday, I think it was.

3035. What was it?—It was the case of a man who was accidentally drowned off Tripcock Point through the upsetting of a pleasure boat on the Sunday week previous. On the 16th, I think it was. The body was recovered five days afterwards in Erith Wash, and it was in a very bad state indeed, disfigured and swollen, and covered with filth and slime and mud. It was an exceptionally bad case, and it was strongly commented upon by the jurymen, though they are used to bad cases down there.

3036. Did you have anything to do with or did you see any of the bodies that were recovered from the "Princess Alice"?—No, I did not.

Cross-examined by Mr. Bidder.

3037. About this case which you refer to, in which an inquest was held by you on the 24th of July; when did you see the body?—I saw it in the mortuary of the parish church at Erith.

3038. When you held the inquest?—Yes.

3039. You would, of course, view the body with the jury?—I did so.

3040. And the man having been drowned on the 16th he had been eight days dead when you saw him?—He had. He had been five days in the water and three days out of it.

3041. And that in the latter part of July?—It was.

3042. I suppose you do not happen to know what the temperature of the river is in the month of July?—No, I do not. It was not warm at that time this year, I think.

3043. You were good enough to say something about the remarks of the jury. I have before me a newspaper report of that inquest, and I find a remark of the coroner's, but no remarks on the part of the jury. Was there anything in the verdict of the jury with reference to the condition of the river?—No, there was not.

3044. Do you know anything of a paper called the "Bexley Observer"?—There is such a periodical, I think.

3045. Did you see the newspaper report of that inquest?—I did not.

3046. Are the newspaper reporters wrong if they represent the only remarks as to the condition of the river as proceeding from yourself?—Yes, they must be wrong. I do not remember if there was a reporter there, even.

3047. It is evident that there was a reporter?—I find that reports go into the papers that are not reported by the officials connected with the press.

3048. Did any one, as a witness, before that inquest make any complaint about the condition of the river?—Yes, many times.

3049. What is the name of the witness?—Arthur Collins.

3050. (*Chairman.*) Do you happen to have your own notes of that inquest with you?—I have not.

3051. (*Mr. Bidder.*) In 1881 you had 32 cases out of the river, I think you said?—I had.

3052. And other cases out of other waters; and you tell the Commission that there was a marked contrast between the condition of the bodies taken out of the river and those taken out of ponds and rain butts and smaller streams?—I did say so.

3053. Is it a fact that as a rule the bodies are very much more quickly recovered in the case of people who fall into rain-butts and small ponds, and that the bodies of people who are drowned in the river are generally two or three or more days before they are got out?—I have taken that into consideration in giving my answers.

3054. Will you be good enough to answer the question. Is it not the fact that the bodies of people who are drowned in the river are usually much longer in the water than those of people who fall into ponds or into rain-butts?—Usually; but not always.

3055. For instance, in the case of this inquest that you have spoken of, this man had been five days in the water?—Yes.

3056. Can you tell me the number of days that the 32 persons that you held inquests on in the year 1881 had been in the water, or any of them?—No, I cannot say; in the case of some as much as a month, I should think.

3057. You were good enough to say that the condition of the river at Greenwich and above is better than it used to be?—In my opinion; speaking from my own observation, it is.

3058. And below Greenwich, do I understand you to say that it is worse?—Yes.

3059. Did you know anything of the condition of the river before the outfalls were open?—I have been up and down the river.

3060. It is nearly 18 or 20 years ago?—I was young at the time.

3061. When you say it is worse, you are comparing it rather with the condition since the outfalls were opened, and not with the condition before the outfalls were opened?—I knew it before the outfalls were opened.

3062. Are you prepared to say that it is worse than it was before the outfalls were opened?—As far as my recollection goes.

3063. May I ask what age you were before the outfalls were opened in 1864?—Sixteen. I am 35 now.

3064. Then you were 17?—About that.

3065. Probably a considerable portion of your me was then occupied in education in some seminary or seat of learning?—Yes.

Re-examined by Mr. Beaumont Morice.

3066. And I suppose that your time was also, some part of it occupied on the water?—Occasionally.

3067. Have you noticed during the past few years any perceptible difference?—I was absent for 10 years, so that I cannot speak until recently.

3068. You have been asked about this report; I see that you are reported to have said ——

3069. (*Mr. Bidder.*) He was cross-examined as to whether the jury had said anything; not as to what he had said.

3070. (*Mr. Beaumont Morice to the witness.*) You were asked whether you were not the only one who made any remark. I call your attention to what you are reported to have said ——

*Mr. E. A. Carttar.*
21 Nov. 1882.

3071. (*Chairman.*) You may ask him what was the remark that he made.

3072. (*Mr. Beaumont Morice to the witness.*) Did you make any remark, and if so, what did you say?—I believe I did make some remark, but I cannot remember now exactly the purport of it, except that it was as to the offensive state of the river.

3073. (*Mr. Lumley Smith.*) The attention of the witness has been called to this paper by my learned friend, and he has been using it for his own purpose.

3074. (*Chairman.*) But the paper has not been put in in any way, and would not be evidence. In fact I have been watching Mr. Bidder to see what use he was going to make of it. He merely asked whether any other person except the coroner had made a remark, and the coroner said the jury did. I think you are entitled to ask the coroner what remark he made.

3075. (*Mr. Beaumont Morice.*) He has been asked by my learned friend whether or not he was the only person that made a remark; and that being so, I submit that I am entitled to ask him now whether he did not make such a remark.

3076. (*Chairman.*) You are going to read to him the passage, and ask him whether that is the remark he made?

3077. (*Mr. Beaumont Morice to the witness.*) Did you make any remark bearing upon the state of the Thames?—I believe I did.

3078. (*Mr. Bidder.*) The observation of the coroner then would be the expression of his opinion, and he can make it now if he has any opinions upon the subject.

3079. (*Chairman.*) He may make it now; but I do not know that Mr. Morice is not entitled to ask him whether he did not make it then also.

3080. (*Mr. Beaumont Morice.*) I will try and meet my learned friend if I possibly can. (*To the witness.*) Have you any opinion with regard to the poisonous state of the river Thames now?—I do not think it is very satisfactory.

3081. (*Chairman.*) You have said that above Greenwich it is satisfactory?—There is a great improvement.

3082. But below Greenwich it is worse; that is your general impression?—Yes.

The witness withdrew.

GEORGE MASTIN called in; examined by Mr. BEAUMONT MORICE.

*G. Mastin.*
21 Nov. 1882.

3083. You are in the Thames Police, and you are stationed on board the police-boat at Erith, are you not?—Yes.

3084. How long have you been there?—Over 3½ years now.

3085. Before that what were you doing?—I was on the Wapping station.

3086. How long have you been on the Thames?—About 25 or 26 years altogether, as near as I can guess.

3087. Do you remember the state of the river before the outfalls were opened?—Yes.

3088. Will you tell us generally what it was?—It was much better than it is at the present time.

3089. In what way?—It was much purer, according to my idea, and there was not the foulness in the water that there is now. The water did not smell so bad.

3090. (*Colonel Ewart.*) What part of the river are you speaking of?—I should say between Crossness and Gravesend.

3091. (*Mr. Beaumont Morice.*) Do you go up and down the river much?—Yes, daily.

3092. And you know the state of the foreshore all up and down?—Yes, between Erith and Beckton.

3093. Can you tell us what sort of mud there is on the banks?—The kind of mud that has a yellowish, slimy look about it; not a sandy soil as it used to be in former years.

3094. (*Mr. Bidder.*) May I submit to my learned friend two things: one, that the real nature of the mud is only to be got at by people who have examined it analytically; another, that its outward appearance can be seen by the Commission themselves?

3095. (*Chairman.*) We have long been sensible of that. This man can only tell us that there is a deposit of a certain colour and texture, and that it is slimy and smells badly, of all which we can judge for ourselves.

3096. (*Mr. Beaumont Morice.*) But the fact of this witness being able to state that, and the fact of my being able to prove it, to the extent to which I am prepared to show it, is of course my very case, not only that it is mud, but that it is mud of a peculiar description, and that is what my learned friend will not admit.

3097. (*Chairman.*) The only peculiarity in the description that he can give is a slimy, bad-smelling mud.

3098. (*Mr. Beaumont Morice.*) And further, that it came there after the outfalls were made; so that these points are of the first importance. (*To the witness.*) Can you tell us what sort of smell it is?—It is a very offensive smell.

3099. Have you ever suffered any sickness or illness from it?—Yes, at times I have had to go out of the boat on account of the smell of the water. That was more in hot weather than in windy weather. I felt very sick; and in fact I have had to vomit once or twice on account of feeling so sick; and that has been when the weather has been very hot and calm.

3100. Are you accustomed to use the water of the river on the boat?—Only for washing the decks of the vessel down with.

3101. Why cannot you use it for other purposes?—On account of the foulness of the water.

3102. (*Chairman.*) The water is dirty, is it?—Very dirty.

3103. And that is the reason why you cannot use it?—That is the reason. At times when we have been cleaning the vessel down, we have had to skim the bucket along the surface of the water on purpose to get the grease and slime off, to get at the water underneath to wash the vessel down with.

3104. (*Mr. Beaumont Morice.*) Why is that?—I should say it is on account of the sewage, or the contents that come from the different sewers.

3105. On the top of the water?—On the surface of the water.

3106. Have you had anything to do with dead bodies that come out of the river?—Occasionally.

3107. In what state have they been?—In a very decomposed state.

3108. When have you had to do with them?—I had one recently that had been in the water four days, and he was lying in the mortuary, and he turned very decomposed.

3109. (*Chairman.*) When was that?—I think he was drowned on the 24th of July, and picked up on the 28th.

3110. (*Mr. Bidder.*) Is that the case in which the inquest was held?—The inquest was held on the body at Erith.

3111. (*Sir John Coode.*) It cannot be the same, because this man was drowned on the 24th, and recovered on the 28th; and in the other case the man was drowned on the 16th, and the inquest was held on the 24th.

3112. (*Mr. Beaumont Morice to the witness.*)—Have you ever noticed at what time the sewage comes out of the outfall?—I have not taken any particular time, because it is such a daily occurrence.

3113. Have you ever noticed when it comes out?—As a rule it has been high water time, and perhaps a trifle before high water, which has caused it to come up the river; that is from the southern outfall; but I cannot state the time.

*G. Mastin.*
21 Nov. 1882

3114. Why do you say that you have noticed that it is sewage coming up?—Because in going up and down the river I always go up and down that shore ; and sometimes when I have been rowing down on the flood tide just below Half-way House, which lies above the sewage, I have met the sewage coming up with the flood tide.

3115. How can you tell that you met the sewage? —By the colour of the water.

3116. What colour is it?—Very black.

3117. Is there any smell from it?—A very offensive smell.

3118. Do you know anything about the Dutch eel-scoots that used to lie in the river?—As a lad I recollect their lying at Erith, but not to form any proper opinion of them. I have seen them lying there.

3119. Do you know how long ago they have dropped coming here?—I could not give a definite date, but it is some years ago; as far as I can guess some 17 or 18 or 19 years ago ; but I should not like to say for a year or two.

3120. Did you see any of the bodies that were drowned in the "Princess Alice"?—Yes.

3121. Where were you then?—In the police-boat at Barking, dragging for them on the morning after the accident.

3122. How many did you get?—I assisted in getting 31 bodies on board the steamboat,—the first bodies that were conveyed to Woolwich.

3123. How long was that after the accident?—But a very few hours.

3124. What state were they in?—They had a very reddish appearance, and they were discoloured.

3125. Did you notice anything else about them excepting that they were discoloured?—I noticed froth coming from several of their mouths.

Cross-examined by Mr. Bidder.

3126. You are not a medical man, I suppose?—No.

3127. You do not know what the symptoms of drowning are?—No.

3128. You said that these 31 bodies were seen by you a few hours after the accident?—Yes.

3129. How many hours after ; four to six hours? —It might have been more. It was under the 24 hours.

3130. You have spoken about the condition of the river. How old are you?—39 last April.

3131. Where were you engaged before you were on the Erith boat?—I was a police officer at Wapping, on the Wapping station.

3132. Which are the bounds of the Wapping station?—As a rule there are beats laid out for the officers to patrol with their boats.

3133. What was the beat that you had to patrol on the Wapping station?—Sometimes it was from Wapping to London Bridge, and sometimes from Wapping to Blackwall.

3134. In point of fact, the station is from Blackwall to London Bridge, and sometimes you have the upper beat, and sometimes the lower beat; is that so?—Just so.

3135. How long were you there?—I think I was on that station about 18 months.

3136. Where were you before that?—On the Gravesend station.

3137. How long were you there?—Nearly four years.

3138. Where were you before that?—On the Blackwall station.

3139. How long were you there?—I should think I was there for about four years.

3140. Where were you before that?—Serving my time on the river in the steamboats.

3141. What sort of boats?—Saloon boats ; the "Alexandra" and the "Palmerston."

3142. Running where?—From London Bridge to Gravesend, Southend, and Sheerness.

3143. (*Sir John Coode.*) How long were you in that service?—Several years.

3144. In what capacity were you working on those steamboats?—As deck hand.

3145. (*Mr. Bidder.*) Now, I understand that you go up as far as Beckton, and down to Erith?—We have no limited distance. It rests with the inspector.

3146. Do you ever get up as far as Beckton?—Daily.

3147. Do you know the Beckton Gasworks?—Yes.

3148. Do you know the sewer there?—No, I do not exactly.

3149. Have you never seen anything of the sewer there?—I have seen the northern outfall at Beckton.

3150. Are you under the impression that when I speak of a sewer at Beckton I am alluding to the sewage at Barking?—I have not seen any sewer at Beckton.

3151. If you tell me that you do not understand the question, I will not ask you any further question. My question is, have you ever seen a sewer at Beckton. Do you understand that question?—Yes.

3152. Then answer it?—You do not refer to the pumping station?

3153. No, I am speaking about Beckton. Do you know Beckton?—Yes.

3154. Do you know the northern outfall?—Yes.

3155. Do you know that the northern outfall is not at Beckton?—I have not been on the ground to know the parish.

3156. (*Chairman.*) You know Beckton, do you not?—Yes, but not the parish of Beckton.

3157. There are some gasworks there, are there not? —Yes.

3158. Is there a sewer there?—I have not noticed one.

3159. You do not know?—No, I do not.

3160. (*Mr. Bidder.*) Have you ever seen anything coming into the river at Beckton?—From the northern outfall?

3161. Is the northern outfall at Beckton?—No.

3162. (*Chairman.*) Have you seen anything flowing into the river at Beckton?—I have not; nothing has come under my notice.

3163. No drain, and no sewer of any sort or kind? —I should not like to say that there is not but I have not noticed one.

3164. (*Mr. Bidder.*) You have never heard of anything coming in there from the gasworks?—No.

3165. When was it that you had to get out of your boat because you felt ill?—I should say that it would be from July to August in the summer before last

3166. When did it last happen?—I did not put it down at the time; but it was about the month of August 1881.

3167. Whereabouts were you?—At Erith.

3168. When you went out of your boat where did go to?—I went ashore.

3169. Where did you go to when you got ashore?— I went to get some refreshment, because I felt so sick and faint.

3170. Did you go to a public-house?—Yes, I could not get any refreshment anywhere else.

3171. Did you stop there long?—No.

3172. When you got to the public-house, what did you have?—I cannot say now, because it is such a long time ago to recollect what I had. I should not like to say.

3173. Are you allowed to land and go to a public-house whenever you please?—No.

3174. You must ask sick-leave?—I was in a boat by myself.

3175. Then you could do as you pleased?—I had no one to ask, if I was in a boat by myself.

3176. Were you in the boat for pleasure, or on business?—I was not on regular duty at the time ; I

*G. Mastin.*

21 Nov. 1882.

was working on one of the boats, cleaning it out; it was in my own time.

3177. Your time was your own?—My time was my own.

3178. Having cleaned the boat out, you landed and went to the public-house?—Before that; I could not stop to finish the boat.

3179. Did you stop long at the public-house?—No, I did not.

3180. Did you go on duty again that day?—No, I did not.

Re-examined by Mr. Beaumont Morice.

3181. Did you leave the boat because you wanted to drink, or because you felt faint?—Because I felt faint.

3182. You felt sick, and you wanted something for it?—Just so.

3183. You have been asked about this sewer at Beckton. Do you know Beckton at all well?—Only from the water side.

3184. You do not know whether there is any sewer there at all?—Not to my knowledge.

3185. But I understand you to say that you have been all your life upon the river?—Yes, I have; ever since I was a lad.

3186. And therefore you have no doubt as to the difference between the state of the river now and what it used to be?—No; there is a great difference.

3187. Can you tell me the distance of Beckton Pier from the northern outfall?—I should say it is from 300 to 400 yards.

3188. (*Mr. Bidder, through the Commission.*) Where were you cleaning that boat?—At the Erith Pier,—inside the Erith Pier.

3189. (*Chairman.*) With respect to these 31 bodies that you got up a few hours after the wreck of the "Princess Alice," did you observe in what condition the clothing upon any of those bodies was?—No, I did not take that notice.

The witness withdrew.

3190. (*Chairman.*) Have you any more witnesses of this character?

3191. (*Mr. Beaumont Morice.*) I have one more, sir.

3192. (*Chairman.*) It is time that we came to something that touches more than the fringe of the case.

Sergeant Charles Gilham called in; examined by Mr. Beaumont Morice.

*Sergeant C. Gilham.*

3193. You are sergeant of the R Division of the Metropolitan Police, stationed at Woolwich?—Yes.

3194. And you have been in the police force for about 10 years?—Yes.

3195. And for, I think, five years you were coroner's officer?—Yes, rather better than that. Before that I was in the navy.

3196. During the time that you have been stationed at Woolwich have you noticed the state of the river?—Yes.

3197. Will you tell the Commission what it is?—Very bad indeed; it is very thick and dirty, too.

3198. (*Chairman.*) Is there any smell?—Yes, very bad in hot weather, especially when they open the penstock from North Woolwich.

3199. (*Mr. Beaumont Morice.*) During the time that you were coroner's officer did you have to do with the "Princess Alice" bodies?—Yes.

3200. In what state were they?—The colour of their clothing was completely changed altogether.

3201. (*Chairman.*) You saw that yourself?—Yes. They were covered with slime and mud. After the bodies were stripped large black blisters came upon the skin, varying in size, some larger than the palm of your hand, and they smelt very badly indeed.

3202. (*Sir John Coode.*) How long after the wreck had these bodies been recovered?—Some the next day.

3203. Is it of those that were recovered the next day that you are now speaking?—Yes, almost all of them. Those which had been immersed longer were worse.

3204. Were the great part of them recovered within 24 hours?—A great many of them.

3205. (*Dr. Stevenson.*) Did you find the blisters in 24 hours, or later?—In 24 hours, that is to say, if the bodies came up anywhere near the Gallion.

3206. (*Mr. Beaumont Morice.*) Was there any stuff on the bodies and clothes?—Yes, a kind of slime, which was very bad. I believe it was sewage.

3207. Was there any smell to it?—It smelt very badly; in fact we had to boil the clothing before we could get it identified in many cases.

3208. (*Sir John Coode.*) Was the object of boiling it to get rid of the accumulation of matter that had taken place in the clothes, or was it to purify the smell?—To purify them; you could not recognise the bodies in most cases. The bodies in many cases were recognised by the clothing, and we had to wash the clothing really because it was in such a filthy state.

3209. Did you take off the clothing and boil it?—Yes, we had one of those steam coppers.

3210. (*Mr. Michael.*) They were put into one of the apparatus that is employed for the purpose of disinfecting clothing, was not that so?—Yes, I believe it was. It was done to identify the clothing.

3211. (*Sir John Coode.*) Did you strip the clothing from the bodies?—Yes.

3212. And then you boiled the clothing?—Yes.

3213. But it could not be identified before it had gone through this boiling process?—No.

3214. (*Chairman.*) What prevented the identification before the boiling process?—The clothes were in such a filthy state, and smelt so badly, that you could not show them to anyone.

3215. (*Mr. Beaumont Morice.*) The clothes were then literally boiled to take the filth off them?—Yes, and dried.

3216. (*Dr. Stevenson.*) Could the clothing have been recognised or not?—Yes, I dare say it could have been recognised. It was not in a fit state.

3217. (*Chairman.*) I understand what you say is this, that they were obliged to boil the clothes because the whole thing was so offensive that they could not show the clothes to the people who came to see them?—That is my meaning.

3218. (*Sir John Coode.*) But in addition to that, I think you said they were boiled for the purpose of identification?—Yes, because it was easier to identify them that way than it would be the other.

3219. Then it was for both purposes?—Yes.

3220. Both for the purpose of purification and for the purpose of identification?—Yes; a great many bodies were entirely identified by the clothing.

3221. (*Mr. Beaumont Morice.*) Subsequently to that, what has been the condition of the bodies that have been taken from that part of the river?—They have been in a very bad state after they have been in the water for a very few hours. After they are stripped and washed they turn quite black in no time.

3222. There is a causeway at Woolwich, is there not?—Yes.

3223. On the ebb-tide what state is that causeway in?—It has to be washed down as the tide recedes. It is very slimy and slippery, and covered with filth—generally black mud.

3224. Is there any smell?—In hot weather particularly.

3225. Have you had to do with any bodies that were taken from any other water except the river?—A good many.

3226. What other water?—From a pond upon the common; from the reservoir.

*Sergeant C. Gilham.*

21 Nov. 1882.

3227. Are they different from those which you take out of the Thames?—Yes; they keep a great deal better. In fact, they turn green before they turn black. It is very seldom that the blisters come on them; in fact, not nearly so quickly. Those blisters that I speak of are of an immense size, some of them containing fluid as black as ink.

3228. (*Sir John Coode.*) Do you mean blisters, or black spots?—Blisters raising the skin right up.

Cross-examined by Mr. Michael.

3229. Do you mean that without the intervention of any other decomposition, the bodies out of the Thames turn black?—Yes.

3230. Like your coat?—My coat is blue; but these are quite black, as black as ink, so that the blisters come out black first.

3231. How long has a body been in the Thames before that condition of things occurs?—I have had them 10, 12, 14, and 20 hours. The longer they are in the quicker they turn black after.

3232. How long after?—Say, for instance, you take a body that has been in the water some 24 hours; before that body is stripped and washed, if it comes from the lower part of the Gallion, particularly off Beckton Gasworks, it will turn bad and blister in less than seven or eight hours after it has been washed.

3233. And it turns perfectly black?—Yes.

3234. You have mentioned the gasworks; do you know the Beckton Gasworks?—Yes.

3235. How do they get rid of all the refuse matter from the Beckton Gasworks?—Well, I believe some of it is sent into the Thames.

3236. How near to the Beckton Gasworks have these bodies been taken out that you spoke of?—I have had bodies right from the Beckton Gasworks close to the pier.

3237. Did they turn black?—Yes, the same thing applied to them as did to the other bodies in other parts of Gallion's Reach.

3238. Are you able to localise the parts of the river from which the bodies turn black when taken out in this way?—I should say particularly from Charlton Pier downwards to the other side of Tripcock Point. I do not know much about the river any further down.

3239. That is from Charlton Pier down to Half-way Reach?—Yes; that would embrace Woolwich Reach and the Gallions. I have not had much to do with the bodies in the river anywhere else.

3240. Were you officer to Mr. Carttar who was here?—I have been.

3241. For how long; for the two and a half years that he has been in office?—I was officer for his father long before that.

3242. Then all the bodies recovered from the river come under your cognizance?—Yes, from that portion of the river, that is to say, below Greenwich, from Greenwich to the lower part of the Gallions, Tripcock Point.

3243. How far does Mr. Carttar's district extend altogether?—It extends right away down the river.

3244. Do any bodies recovered between Rotherhite and Gravesend come within your jurisdiction?—From the lower part of Greenwich to Tripcock Point.

3245. Are you able to say that there is a difference between bodies recovered off Greenwich and bodies recovered off the Beckton Gasworks?—Yes, and there is a considerable difference in those recovered off Charlton.

3246. And those are the ones that turn black, as you have described?—No, they turn more green; in fact they keep better if they come up off Charlton.

3247. Then it is only in a very limited portion of the river that this blackness occurs?—The portion of the river that I am speaking of.

3248. Putting Beckton as the westerly point, how far does it go down to the east?—It comes right up, I should think, to the Woolwich Dockyard.

3249. That is going the other way, to the west?—I do not know of anything below Tripcock Point.

3250. You said something about the discharge from the penstocks at North Woolwich; is the river very bad when those penstocks are opened?—Yes, the water is discoloured for some considerable distance, and in the warm weather it smells very badly.

3251. How often does that occur?—That I could not exactly say; I believe once in every 24 hours; but of that I am not positive.

3252. How often have you seen it?—I have seen it several times, but I could not say how often.

3253. How often has the penstock been opened when you have seen it?—I could not say, but I have noticed it when I was on the water.

3254. (*Sir John Coode.*) When you speak of the penstock at North Woolwich, I suppose you mean the penstock at Barking Creek?—There is a penstock at North Woolwich which contains the sewage of North Woolwich and the sewage of part of East Ham, which is emptied in the river, I think, every 24 hours.

3255. From about what population would the sewage drain into this penstock?—From the whole of North Woolwich and a portion of East Ham.

3256. (*Sir John Coode.*) Have you any evidence as to the population draining into this penstock?

3257. (*Mr. Michael.*) We shall be able to give you the entire details, but it has nothing to do with our sewer.

3258. (*Mr. Beaumont Morice.*) It is within the metropolitan district, I think.

3259. (*Mr. Michael.*) A portion of it is not in the metropolitan district.

3260. (*Mr. Lumley Smith.*) The outfall is.

3261. (*Mr. Beaumont Morice to the witness.*) You say that all that you know is down as far as Tripcock Point; that is nearly opposite Barking, is it not?—Nearly opposite Barking.

3262. And it was opposite Tripcock Point that the "Princess Alice" was run down?—Yes.

3263. You say that coming along Gallion's Reach, up to Woolwich and Charlton Piers, is where the bodies that you have to do with are found?—Yes, principally.

3264. And you say that you find that the bodies which are taken out along that part of the river very soon become discoloured?—Yes, they become quite black.

3265. (*Chairman.*) The bodies which you describe as being blistered you find somewhere near Charlton Point?—In Gallion's Reach, more so than in any other parts.

The witness withdrew.

*Capt. G. B. Lynch.*

Captain George Benjamin Lynch called in; examined by Mr. Beaumont Morice.

3266. I believe you are the principal dockmaster at the Gallion's entrance of the Albert Docks?—Yes.

3267. How long have you known the Thames?—I recollect it well for 40 years.

3268. Do you remember before the outfalls were made?—Yes.

3269. Can you tell us what was the state of the river before that time?—It was sometimes bad and sometimes pretty good. We used to dip our water when we lay off the Custom House, in steamers. I have known it to be a little bad in the summer time, but at other times it was very clear.

3270. Since the outfalls have been made, have you noticed any difference at all?—Yes, the water has been thicker.

3271. Is there anything else?—The accumulation of the mud on the banks is blacker, I consider.

3272. Is there any smell?—Yes, it smells very badly in the hot weather; you do not observe it much in the cold weather.

3273. (*Chairman*). Of what part of the Thames are you speaking?—Between the Victoria entrance and Gallion's entrance.

3274. (*Mr. Beaumont Morice*). That will be from Woolwich, down Gallion's Reach to Tripcock Point?—Yes.

3275. Have you noticed any alteration with regard to the mud about the entrance of the Albert Dock?—Yes, frequently. The water is black at times on the flood tide; you will see black water coming through the piles of the pier heads.

3276. Has there been any increase of this in the last few years?—Yes, I think so, from the accumulation of the mud in the basins of the docks.

3277. Have you more difficulty now in clearing it away than you used to have?—In the Albert Dock it has accumulated very fast in the last two years. The dock has been opened a little over two years, and there is a great deal of mud in that basin.

3278. Have you ever noticed any ill effects from this stuff about the docks?—I have found the men complain of the smell of the water at times.

3279. Do you ever use the water for anything now?—Oh, no.

3280. Why not?—It is not fit.

3281. Why is it not fit?—It is discoloured and dirty.

3282. (*Chairman.*) Is it the colour that makes it objectionable?—And it is thick also.

3283. Have you any other reason for not using it?—There is a sort of oily nature or appearance on the surface of the water at times.

3284. Have you any other reason for not using it?—From knowing that it is dirty and thick, we should not use it for any purpose at all.

3285. (*Mr. Beaumont Morice.*) Have you ever noticed any solid matter floating in the water?—Yes, frequently.

3286. Can you tell us what it has been?—Filth from the closets and that sort of thing.

3287. That you have seen?—Oh, yes.

3288. Often?—Occasionally.

3289. Have you ever noticed the sewage passing up the river?—Yes; the black streaky marks in the tide way.

3290. Can you tell us from your own observation at what time the sewage generally comes out of the river?—I have noticed the discolouration in the water at about half flood.

3291. Have you ever seen any dead fish about the banks of the river?—Yes, frequently.

3292. When did you last see them?—Last summer.

3293. What were they?—Eels and small flounders.

3294. Did you notice them at any particular time of the year?—In the summer months.

3295. Have you often seen them?—Whenever you see eddy tides, at the time the tide is running up generally.

3296. That is the eddy tide inshore, is it not?—Yes; you see these things in where the tideway is.

3297. Is the mud that is deposited in the docks now different from what it used to be some years ago?—Yes, I think it is of a blacker appearance.

3298. Is there any other difference?—It smells very much.

3299. Do you know any of the factories on the shore in that neighbourhood?—Yes, there are several between the Albert entrance and the Victoria entrance.

3300. Do they smell at all?—Yes, a little.

3301. Is there any difference between their smell and the smell of the sewage that you have told us about?—Yes, I think there is a difference.

3302. You cannot mistake one for the other?—I think there are nitro-phosphate manure works; that is about the strongest smell.

3303. That you are able to identify?—Quite so.

3304. Have you ever felt any ill effects from this yourself?—Not particularly.

3305. Have you felt any sickness?—Just a very little.

3306. Have any of your men felt it?—Yes, I have heard them complain. I have seen men sick and known men to be sick from it. It will affect some men more than others.

Cross-examined by Mr. Bidder.

3307. You did not inquire, did you, what these men had been doing or having previously?—They had been working at the lock side or the pier head.

3308. You did not know where they had spent the previous evening?—No.

3309. You have never been sick?—No, not really sick from that cause.

3310. Did I rightly understand you to say that you have observed an alteration at the entrance to the Albert Docks in the condition of the mud and the amount of mud in the docks, of recent years?—Yes, I think so.

3311. Am I not right in this, that those docks were only completed two years ago?—They have been opened two and a half years.

3312. And therefore, the only time during which you can draw any comparison as to the state of the stream or the state of the mud in the basin of the Albert Docks is within the last 2½ years?—Yes. I can compare it with the Victoria entrance.

3313. Which is in quite a different part of the river?—Yes, higher up.

3314. You are speaking now of what takes place at the Albert Dock entrance as compared with what used to take place at the Victoria Dock entrance?—

3315. (*Chairman.*) It is, as I understand, one dock with two entrances from 2½ to 3 miles apart?—Yes.

3316. (*Sir John Coode.*) What is the distance of the Albert Dock entrance from the northern outfall?—It is about three quarters of a mile, I should think.

3317. (*Mr. Bidder.*) And the distance of the Victoria Dock entrance from the northern outfall is about 3 miles?—Yes, a little over 3 miles.

3318. So that when you talk about there being more mud, what it comes to is this; that you find more mud at the Albert Dock entrance than there used to be at the Victoria Dock entrance?—The basins accumulate the mud faster, I think. The mud accumulates in both basins more than it used to accumulate.

3319. Have you ever heard it suggested that the Albert Dock entrance is put in a place that makes it very liable to be mudded up?—It is an eddy tide there on the ebb-tide.

3320. And, in point of fact, so liable is it to be mudded up, that you have had to make two great horn works; that is part of the design, is it not, to keep the mud from the dock entrance?—There are two pier-heads; but that does not keep the mud out.

3321. But that is what they are intended for, is it not?—I think not; I think they are for docking purposes—for docking the ships.

3322. It was hardly necessary to have gone so far into the river for that purpose. How long have you known the Victoria Dock?—Since it was opened.

3323. Was not the Victoria Dock always considerably troubled with mud?—Yes.

3324. When were the Victoria Docks opened?—In the year 1855.

3325. And they were always from the beginning very much troubled with mud?—Yes, we had a little mud.

3326. And very large quantities had to be dredged up and sent away in barges?—Yes.

3327. I will not ask you much about the flounders in the river; but there are a good many fish in the Victoria Docks, are there not?—There used to be.

3328. And there are now?—I think not.

3329. They catch jack there, do they not?—In former years they did; I do not think there is any fishing going on there now.

3330. Are you quite sure?—I would not be quite positive.

3331. How long is it since you have known people

*Capt. C. B. Lynch.*

21 Nov. 1882.

come to the Victoria Docks for a day's fishing?—I have not seen any there for these five or six years.

3332. When you say that you have noticed the sewage on the flood tide, I understand that what you have noticed is a discolouration of the water?—Yes.

3333. Do you say that you have seen that at half flood?—Yes.

3334. When did you last see it at half flood?—A month or two ago. In the hot weather it shows most. I saw it in August.

3335. Do you know North Woolwich?—Yes.

3336. Do you know the penstock there?—No, I do not.

3337. Do you know the place where the sewage discharge from East Ham and North Woolwich is?—No, I do not.

3338. Have you never heard of any sewage discharge there?—No; I have heard of the overflow water discharge.

3339 You are close to the Beckton Gasworks, I believe?—We are.

3340. Do you know anything of the arrangement for getting rid of the refuse from the gasworks?—No, I do not.

3341. Did you ever see a sewer there?—No.

Re-examined by Mr. Beaumont Morice.

3342. Vessels do not dock on the ebb tide, do they?—Very seldom.

3343. Then those piers are made for vessels coming upon the flood in order that they may go into the dock all right?—Yes, they are; those piers are for the express purpose of docking.

3344. And, notwithstanding that, they do not keep out the mud sufficiently?—No.

Examined by the Commission.

3345. (*Chairman.*) How long have you been connected with the Victoria Docks?—Since the opening of the Victoria Docks; 27 years.

3346. You have been asked whether there has not been a great deal of dredging necessary in the docks when did that begin?—We have been dredging in the Albert Dock basin this last month.

3347. That is quite a new dock, is it not?—Quite a new dock.

3348. But Mr. Bidder asked you whether you have not been for a long time obliged to dredge or to clear out the mud in the Victoria Docks?—Yes; about every three months we dredge the basin out there.

3349. (*Mr. Bidder.*) The witness said, in answer to me that they have done so, from the first, about every three months.

The witness withdrew.

Mr. James Henry Showell called in; examined by Mr. Beaumont Morice.

*Mr. J. H. Showell.*

3350. I believe you are an inspector of the Watermen's Company, and you live at Greenwich?—Yes.

3351. You have a district down the river, have you not?—Yes, boarding barges and craft on this river.

3352. On behalf of the Watermen's Company?—Yes.

3353. What is your district?—From the top of Limehouse Reach to Erith, or a little below.

3354. What do you board these craft for?—To see that the Act of Parliament is carried out.

3355. How many years have you been on the river?—It is 24 years on the 13th January since I was apprenticed on the river.

3356. And you know the river from Greenwich down to Erith or Gravesend pretty well?—Yes.

3357. Do you remember the outfalls being opened at Crossness and Barking?—Yes.

3358. Do you remember the river before that and since?—Yes.

3359. Is there any difference in the water?—Yes, very much.

3360. What difference is there?—The filthy state of it, the great amount of sewage in it, and the difference in the colour of the water.

3361. Is there any smell from it?—Yes, there was the summer before last; last summer it was not so bad. It was in the summer of 1880–81 particularly that I noticed the water being so bad.

3362. Have you ever noticed the sewage in the river specially?—Yes.

3363. How do you notice it?—By the thickness of the water; and by the mud, which is in a very bad state to what it used to be; and by the dreadful stink that there is attached to it.

3364. Take the mud all up on the south shore from Erith say up to Tripcock Point, what is the difference between the mud now and what it used to be?—Formerly it used to be of a whiter colour than it is now; it is more of a black colour at the present time.

3365. Is there any smell about it?—Yes, it stinks very much.

3366. Do you remember when the Dutch eel boats used to come off Erith?—I do not remember them so well off Erith, only once I remember bringing a freight of eels in a corfe.

3367. You had to do with them, had you not?—Yes.

3368. How long ago was that?—From the time I was apprenticed at the age of 14.

3369. How many years ago is that?—About 10 or 11 years ago was the last time that I worked for them.

3370. Where did you work for them then?—I first worked for them at Gravesend, lying at the "Lobster."

3371. What did you do?—The vessels used to come from sea and lie at the "Lobster," and we used to work the eels out from vessels in boxes, and bring them up to market every night.

3372. Where do they lie now?—At Hole Haven.

3373. Has anybody told you why they lie down there?—I knew from my own experience.

3374. But you have never been on those boats yourself?—I have worked for them and brought the eels out of the vessels.

3375. And, as a matter of fact, you know that they have been lying down at Hole Haven?—Yes.

3376. Have the people there told you why they were lying at Hole Haven?—It came under my notice principally to arrange the shifting of the vessels down at the time, on account of the water being so bad.

3377. Nobody told you anything?—Nobody told me anything. The Dutch people listened to us because of our knowledge of the water.

3378. (*Chairman.*) It was by your advice that they lay down there?—By my advice as well as that of other watermen.

3379. (*Mr. Beaumont Morice.*) And they took your advice?—They took my advice. There are three companies of those vessels working here, and there were other watermen working for the other companies, and we found that the eels would not live.

3380. So they went down to Hole Haven?—Yes.

3381. In which part of the river is it that this sewage smell is the worst?—The worst that I ever noticed was in Woolwich Reach, on the north shore.

3382. At what time of the tide?—Just on the young flood, just as the tide was making.

3383. That would be nearly low water, would it not?—The tide was flowing.

3384. Have you ever noticed any sewage matter or solid matter floating in the river?—Yes, frequently; and lots of things come down from the sewers as well.

3385. Sewage matter?—Yes.

3386. Have you ever suffered any ill effects from this stink?—In the summer of 1881 I was very sick one day at Woolwich, and I went ashore out of it. I told my men to row the boat to shore, and I got out of it.

3387. And I take it that when you went ashore you did not feel it?—No, I got away from it.

3388. Have you ever suffered from it so as to be unable to perform your duties?—No, I do not know that I have. I have felt very queer, but have still managed to perform my duties.

3389. Can you tell us, from your knowledge of the river, how far the sewage would go down the river on the ebb tide?—I should say about the lower end of Gravesend Reach.

3390. (*Sir John Coode.*) Do you say that from observation?—I should think we should drive that far from the outlet.

3391. But what makes you think it?—By driving. I have driven the tides many times about the river, and I should say from my own judgment that it would be there. I should say that we should drift about that distance with the tide; perhaps not quite so far; but I should think that the sewage would go faster than the tide, because a boat stands up against the wind.

3392. You ground that opinion upon the point to which you think a boat would drift with the tide?—Yes, I should think she would drift about that distance.

3393. (*Mr. Beaumont Morice.*) Have you ever drifted in a barge below Gravesend on the tide?—Yes, in a boat, I have been below Gravesend, but not to take particular notice.

3394. You have come up, have you not, from lower down the river, from the Nore way?—Yes.

3395. In coming up from the Nore into the river, can you tell the Commission what difference there is in the state of the water?—In Sea Reach you will find the water very clear, especially on the flood tide; but as you come up so you will find that it gets thicker and thicker from out of Sea Reach until you get up to the top of Limehouse Reach; and then you will find it will clear a little after that.

3396. Can you tell us at what point you begin to notice that it changes?—You would notice it as you entered the Lower Hope, coming into Gravesend Reach.

3397. Have you ever noticed any settlement of the sewage up and down the river?—Yes, frequently along the shores in the different bights.

3398. Has that been more so within recent years or not?—Yes, more so of recent years.

3399. Before the outfalls were opened was there anything like the smell from the mud that there is now?—No, not down from that part of the river.

Cross-examined by Mr. Bidder.

3400. How old are you?—Thirty-eight on the 10th of next January.

3401. To begin with the Dutch eel-boats, I understand that they used to stop at Erith, and the watermen recommended them to go to Hole Haven?—They stopped at Erith before my time.

3402. You never knew them stop at Erith?—I once towed a corfe with eels from Erith up to London.

3403. When you began, the Dutch vessels used to stop at Hole Haven?—The very first voyage that I ever had was from Gravesend and finished at Hole Haven.

3404. How far is Gravesend from Hole Haven?—about eight miles.

3405. When did you first go to Hole Haven?—I do not know the year; it was when I was apprenticed, and certainly after the sewers were let into the river.

3406. When were you apprenticed?—I was apprenticed three days after I was 14.

3407. How long were you apprenticed?—Seven years.

3408. Then you ceased to be an apprentice 17 years ago?—Yes.

3409. That is just about the time when the outfalls were opened; and the Dutch boats, you say, went to Hole Haven whilst you were an apprentice?—Whilst I was working on the water. I have been working on the water all my life.

3410. Have you anything to do with the Dutch eel boats now?—No.

3411. Do you ever see them?—Yes, but I do not go on board of them. Of course I frequently see them on the river.

3412 You do see the Dutch eel-boats?—Frequently.

3413. When you say that they went to Hole Haven by your advice, you must have been very young to give advice?—I said my partners and the other watermen with me.

3414. I suppose the watermen get a better fare from Hole Haven than from Erith?—No, you cannot call it better, because we used to do it from Gravesend for 20*s.* for a single hand, and after we shifted to Hole Haven we had 25*s.* for two hands; so that it was against our interest.

3415. Do you ever see the Dutch boats on the river?—Yes.

3416. You see them going up the Pool?—Yes, frequently; two came up last week with eels in them alive.

3417. Are the eels in the Pool alive?—Yes, they always were from the time I was an apprentice, in the winter time.

3418. And that is so now?—Yes.

3419. Those eels of course are carried in the well?—Yes.

3420. And I suppose that if one took the trouble to go down to Billingsgate or wherever they lie, one would see those boats in tiers now in the river with their wells full of eels?—Yes; there are some there now to-day. At this time of the year they always come up in the winter time.

3421. You have spoken of the smell in the river; I understand that the place which you identify as being that where you have detected the most distinct and offensive smell is on the north shore at North Woolwich?—Yes.

3422. Was it near the ferry pier?—Close to the pier.

3423. And just about ebb-tide?—No, on the young flood.

3424. Do you know the Penstock at North Woolwich?—Yes, just below Henley's place.

3425. How far is that above the ferry pier?—That I suppose is 500 or 600 yards; but on the flood tide, if anything was coming out, it would certainly go above where I was.

3426. I did not ask you that; I asked how far off it was. Have you ever seen the sewage discharged out of that?—No, it is under water at low water.

3427. It only discharges near low water, does it?—I do not know what time it discharges; I never noticed that. You cannot see the outlet; the tide never leaves it; it is an iron pipe that goes down into the river.

3428. Have you heard complaints about it?—No.

3429. Do you know the Beckton Gasworks?—Yes.

3430. Did you ever see any sewage coming from there?—No. I never did.

*Mr. J. H. Showell.*

21 Nov. 1882.

3431. Have you ever seen any pipe or sewer at the Beckton Gasworks?—I do not know that I ever noticed any.

3432. You never smelt anything coming from them?—As you go by there you can smell the gas liquor that they are loading the barges with.

3433. Have you seen the liquor come into the river?—No.

Re-examined by Mr. BEAUMONT MORICE.

3434. It depends a good deal upon the time of the year when the boats come up with eels, does it not?—Yes.

3435. Does it not depend upon the amount of fresh water that is coming down the river?—Yes, in winter time there is always a good down tide with plenty of fresh water, and the eels would be better in London than they would be even at the top of Sea Reach.

3436. You know the sort of wells that they have in those boats?—Yes, they are copper wells with very small holes in them.

3437. Open to the river?—Open to the river.

3438. You say that you do not know anything about the sewage at Barking or at Beckton?—I do not.

Examined by the COMMISSION.

3439. (*Dr. Stevenson.*) Do the eel-boats come up in the summer in that way?—No, they could not come up in the summer.

3440. Why not?—On account of the badness of the water; it would turn all the eels up.

3441. (*Chairman.*) What makes you say that it would do so?—I have seen that it has done so.

3442. But it does not do so in the winter?—No.

3443. (*Mr. Bidder, through the Commission.*) In the olden time, when you were an apprentice, when they stopped at Erith used they to come up in the winter time?—Yes, all the year round, ever since I can remember, and I have heard people say before me, that they always came up in the winter time.

3444. (*Chairman.*) They come up in the winter time now; but did they come up in the summer time?—No; they used to work the eels at that time of day up in corves through the water from Erith right up to London. Then when the water began to get bad we used to bring them up in boxes from Gravesend, and that is the way they bring them now from Hole Haven.

3445. (*Mr. Bidder.*) Towing them?—No; bringing them up in the boats. They are not in the water now; they are in dry boxes.

3446. (*Dr. de Chaumont.*) Not even during the winter?—We never work them up in the winter from below, because they came to London as they do now.

3447. Then are the eels in the wells now?—Yes, in London, as they lie now.

3448. Have they been in the wells all the way up?—Yes; they tow up by steam and the vessels come through the water so fast that it is does not give the sewage or any filth the opportunity of settling in the wells; they keep getting fresh water.

3449. (*Chairman.*) In point of fact the eels remain in the wells, and they are towed up to the market in the winter time.

3450. (*Mr. Bidder.*) About how many tons of eels are there in one vessel?—About 12 tons. We use to bring out 12 boats of eels, and we reckoned each boat of eels was about a ton.

3451. And those eels as they lie at Billingsgate are supplied with river water?—Yes.

3452. And are living for days on it?—Yes, but they are better at low water than they are on the flood.

3453. (*Sir John Coode.*) You told us that you thought the sewage would extend as far down as the lower end of Gravesend Reach, and that you came to that conclusion because a boat would drift so far; have you ever seen any discolouration of the water as far down as that?—I have noticed the fact of the water being thick there

3454. Thick with what?—With darkness in the water; not clear like it used to be.

3455. Then you say that the water is different in appearance at the lower end of Gravesend Reach from what it used to be?—Yes, in my opinion.

3456. (*Dr. de Chaumont.*) Is it offensive at all to the smell?—Not at this time of the year; you would not notice it so much now.

3457. (*Chairman.*) Is there any sewage discharged into the river at Gravesend?—I think there is somewhere above the canal.

3458. Would that account for the discolouration that you speak of?—I do not know that it would much. That sewer was there when our vessels used to lie there, and it never affected the eels.

The witness withdrew.

Mr. JAMES WILLIAM ROZIER called in; examined by Mr. BEAUMONT MORICE.

*Mr. J. W. Rozier.*

3459. I believe you are the chief inspector of the Watermen's Company?—Yes.

3460. You have been 18 years in the service?—I have.

3461. Will you tell us shortly, do you remember the river before the outfalls were open?—Yes.

3462. What is the difference between then and now, if any?—In the year 1860 I lived at Dagenham, just opposite Crossness. I lived there, I should think, about 12 months. I was living there nearly all the year 1860.

3463. Since that time what part of the river have you been on chiefly?—I have been on all parts of the river.

3464. Do you know the part from Woolwich to Gravesend?—Yes.

3465. Has there been any difference in that since 1860?—Yes, a wonderful difference.

3466. In what way?—There has been a difference in the state of the water; the water has been very bad since then.

3467. In what way has it been bad?—I should lay it to the sewage.

3468. (*Chairman.*) You are not asked what you would lay it to; but what makes you say that it has become bad?—The water has become a different color.

3469. (*Mr. Beaumont Morice.*) Is there anything else besides the colour?—Yes, the stench as well.

3470. Have you noticed anything else about it?—Those are the two principal things.

3471. The colour and the stench?—Yes.

3472. Have you ever noticed bodies that were taken out of the water?—Yes.

3473. In what state were they?—They were black.

3474. Was there anything about their clothes, any mud, or anything of that kind?—Yes, slime. At the time of that sad disaster to the "Princess Alice" I was there every day, and I had a good chance of seeing all the bodies that were picked up, or the best part of the bodies, fetched on shore.

3475. What were they like?—They were black, with filth on their clothes, a kind of slime.

3476. You know the mud on the foreshore down the river; is that different from or like the mud that there used to be?—It is quite like ink in a manner of speaking, quite black.

3477. Is there any smell with it?—Yes; when the weather is warm in the summer time a very offensive smell comes from the mud.

3478. At what time of the tide is this smell the worst?—On the ebb tide, when the tide is any way down drawing towards low water.

*Mr. J. W. Rozier.*

21 Nov. 1882.

Cross-examined by Mr. BIDDER.

3479. When you were living at Dagenham for a twelvemonth what were you doing?—I was taking the fish refuse away from Billinsgate Market.

3480. What did you do with it; where did you take it to?—It went on shore at Dagenham to make manure with.

3481. And at that time there were no offensive smells of any kind on the river?—No; the worst smell that I had to contend with was the smell from what I was taking there at that time.

3482. Possibly you used to row your barge?—It was what they call a lug-boat.

3483. You used to take it full of refuse from Billingsgate?—Yes.

3484. And when you were sitting with this refuse in front of you, you did not detect any smell from the river?—No, only the smell that I had in the boat.

3485. You could smell that?—Yes, quite plainly.

3486. Have you tried the river recently with a boat load of fish refuse to see if you could smell anything else?—No, I have not been engaged in the work since then.

3487. Now about the wind. Where have you been smelling the wind lately?—When I have been in one of our skiffs I have noticed it with the steam boats going down at low water time, the paddle wheels stirring it up.

3488. Did you ever try to smell the mud in the olden days?—Not particularly.

3489. But there again I suppose your fish refuse was a considerable protection to you, was it not?—Well that was a stench, I must admit.

The witness withdrew.

3490. (*Chairman.*) It is the feeling of myself and my colleagues that we have had a great deal of this kind of evidence, and I do not know that you strengthen your case, Mr. Morice, by bringing in more evidence of the same kind. At the same time, of course we do not wish to dictate to you in any way as to how you should conduct your case. Recollect, we are not a jury; but most of the gentlemen about me are gentlemen of great experience and technical knowledge who are able to appreciate this kind of evidence; and we should like to come to something nearer the heart of the matter.

3491. (*Mr. Beaumont Morice.*) I am much obliged to you for the suggestion. A large amount of evidence has been furnished to me to prove the points which I have submitted to the Commission, and it is undoubtedly my case here on behalf of the memorialists who, of course are a somewhat large body of persons, that there is a great deal of evidence to this effect, and there are a large number of persons who are persuaded that this pollution is a nuisance, and has been caused by the sewage from Crossness and Barking. At the same time I have different classes of evidence, and if it meets the views of the Commission, I do not wish to go further with any particular class than the Commission may think fit. But having regard to the number of witnesses, and the various classes of evidence which have been tendered to me, I think, that acting on behalf of the memorialists, I am hardly in a position to withdraw any particular class of evidence from the Commission until the Commission think fit to suggest the same to me.

3492. (*Chairman.*) I think that is very fair; but the fact is that we have had a great deal of this kind of evidence. We do not doubt the respectability and *bona fides* of your witnesses, but we are able to appreciate the weight that is justly due to their evidence, and we doubt very much whether you would strengthen the case by calling three times the number of witnesses into this room for the purpose of repeating what their predecessors have already told us. If you have evidence of a different class to lay before us we shall be only too ready to receive it.

3493. (*Mr. Beaumont Morice.*) Perhaps you will allow me to say that the great point that the memorialists have in view is to show the Commission how widespread the experience and the feeling on this matter is: and that being so, I really think that the Commission themselves would hardly feel satisfied, unless a variety of evidence were brought before them, in order to show the extent to which this feeling exists.

3494. (*Chairman.*) How many more witnesses have you of this character?

3495. (*Mr. Beaumont Morice.*) At the moment I do not think that I have above one or two more of that character, because I was thinking, with your permission, of taking witnesses of a different class to-morrow.

3496. (*Chairman.*) We shall examine the river very carefully ourselves.

3497. (*Mr. Bidder.*) If I might throw out a suggestion to my learned friend, instead of calling a lot of very respectable, but for this purpose, uneducated gentlemen, to say that the mud is brown or black or yellow, he can bring scientific gentlemen to tell us what the mud is.

3498. (*Mr. Beaumont Morice.*) The persons who are affected and who are best able to speak upon a matter of this kind are persons of the class to which my learned friend refers.

3499. (*Chairman.*) Unquestionably; but we have had a great many witnesses who have already spoken on that subject; so many that we must see that their complaints are very well worthy of attention. Whether you would strengthen your case by calling as many more who will come and tell the same story seems to us more than doubtful.

3500. (*Mr. Beaumont Morice.*) I am much obliged to you, sir, for the suggestion, and I will consider it.

Adjourned to to-morrow at 1 o'clock.

# SEVENTH DAY.

## Wednesday, 22nd November 1882.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

CAPTAIN JAMES HUSSEY called in, and examined by Mr. BEAUMONT MORICE.

3501. I believe you are the principal dock-master of the East and West India Docks?—Yes.

3502. How long have you been there?—32 years.

3503. Will you tell us shortly whether there has been any difference in the accumulation of the mud at the entrance of the docks in the last few years?—

*Capt. J. Hussey.*

22 Nov. 1882.

*Capt. J. Hussey.*
2 Nov. 1882.

There has been an enormous difference in the last three or four years, and especially this year.

3504. (*Professor Williamson.*) Do you mean that there has been more mud deposited?—Yes.

3505. (*Mr. Beaumont Morice.*) Do you remember when the outfalls were opened?—Yes.

3506. Is there any difference in the accumulation of the mud between the time before the outfalls were opened and since?—At first there was a decrease in the mud after the outfalls were opened.

3507. And since then what has happened?—Since then it has been gradually increasing, working its way up.

3508. Will you tell us what sort of mud it is?—It has a very large proportion of sewage mixed with it. I may say, for instance, that three years ago, say in 1879, 69,000 tons of mud raised cleared the whole of our docks and basins, which I suppose cover an area of about 120 acres. This year I have already raised 90,000 tons, leaving an accumulation of something like 70,000 tons; in fact I have been obliged to employ a contractor to do one basin, because the mud has overpowered me.

3509. And you say that it is sewage now?—A large proportion of it is sewage. My house is within 20 feet of the river, and after a still night, when there is not much motion, when the mud settles on the banks, the stench from it is something awful in the summer time.

3510. Are there any factories near where you are on the land?—No.

3511. Have you ever suffered any illness?—I have not personally, but my grandchildren and my family who are in the house have suffered. They lived there in the summer time while I was away on my holiday, and they were taken ill; both my son-in-law and his children.

3512. Were they ill while you were there at all?—Yes, when I came back, because they telegraphed for me, and I came back directly.

3513. And you saw them?—Yes.

3514. Can you tell us, from any observation of your own, at what time the sewage passes up by the docks?—It is working up very gradually. It took, I should think, nearly two years, or more than that, say 2½ years, to reach our place from the outfall.

3515. Can you tell us at what time of the tide the sewage comes out from the outfall?—I think it is first quarter ebb.

3516. (*Mr. Bidder.*) Are you down there?—No, I am not.

3517. (*Mr. Beaumont Morice.*) You have not seen it come out yourself?—Yes, I have. Where we land our mud adjoins the pumping station at Crossness.

3518. Have you noticed the sewage come out into the river?—Yes.

3519. Can you tell the Commission at what time of the tide it comes out into the river?—I should say about a third or a quarter ebb.

3520. (*Professor Williamson.*) You mean the first quarter of the ebb tide?—Yes.

3521. (*Mr. Beaumont Morice.*) Have you seen the sewage further up the river at all than the outfall?—We have got it at the back of my house.

3522. How far would that be from the outfall?—Eight miles; and we have it also in our locks, because I am always dredging, and of course I see it every day.

3523. How can you tell that what you are dredging is mixed with sewage?—I can tell that it is mixed with sewage by the effluvium of it; and besides, having so many years' experience of mudding, I can tell by the appearance of it, by the slimy greasy look it has, and by the feel.

3524. Have you ever seen the sewage bove your place?—Yes, it has got up now, I should say, as far as Limehouse.

3525. (*Chairman.*) You have seen it as far up as Limehouse?—Yes.

3526. (*Mr. Beaumont Morice.*) When was it that you saw it at Limehouse?—About a week ago. I tried some of the mud there because our docks extend up to Limehouse.

3527. And you found it mixed with sewage?—Yes; that is the way I test it—by the smell and the feel.

3528. Can you tell us whether the flood tide is stronger than the ebb?—It is.

3529. Would it therefore, or not, bring anything further back than the point from which it started on the ebb?—Yes; it goes some considerable distance down, but the flood tidal wave will overpower it. It is a singular thing that, although the ebb tide runs one hour longer than the flood, the flood seems to overpower the ebb tide. In fact, I have formed an opinion that it will reach up here in about 18 months' time.

3530. (*Mr. Michael.*) From now?—From now.

3531. (*Mr. Beaumont Morice.*) Have you ever had any of the actual sewage from Barking in your docks?—Yes. I suppose it all comes both from Crossness and from Barking too. I cannot distinguish them.

3532. Is there any special time more than another when you have any?—No. Sometimes, when there is an accident at the Barking outfall, they pump it into the River Lea, and then we get a dose of it.

3533. Has that ever happened?—Yes, some stoppage of the pumping station at Barking.

3534. (*Chairman.*) That is up in Barking that they pump it into the Lea?—No; it is at the pumping station at Bromley where they pump it into the Lea.

3535. When there is an accident at Barking, then their sewage, you say, is put into the Lea, and you get a dose of it?—Yes.

(*Mr. Lumley Smith.*) The storm overflow is at Bow Creek in the River Lea.

(*Mr. Michael.*) That is a totally different matter.

3536. (*Mr. Beaumont Morice to the witness.*) On those occasions you have an unusual quantity of it?—Yes.

3537. Have any of your men, to your knowledge, had any illness owing to this?—There is only one man who has. I do not know it from my own personal knowledge.

3538. Can you tell us, from your own observation, how far, up to two years ago, the sewage extended up the river?—No, I cannot. Till it came to our place I did not notice it.

3539. Have you any means of knowing, from your own experience, how far it has been up the river, say from year to year, lately?—According to what I have noticed myself, I have calculated, and it is my opinion, that it works its way higher up at the rate of about three-quarters of a mile a year.

3540. (*Professor Williamson.*) Could you give us some particulars of the observations which you have made upon that point; where it was in some one year, and where it was in some subsequent year?—It seems to me gradual. Our place extends from Blackwall to Limehouse, about 3½ miles; and I have calculated from that, and from the first time I noticed the sewage, which was about the year 1879, up at our docks.

3541. (*Chairman.*) What point had it reached in 1879?—The East India Docks.

3542. Did you notice it the following year?—I did.

3543. How far had it reached the following year?—About 200 yards, I reckon, from our south dock entrance at Blackwall.

3544. Then in the year after that, did you notice it again?—I noticed it again.

3545. What did you notice in that year?—I noticed that it had got to a dry dock about three-quarters of a mile further up, above Cubitt Town Pier, opposite East Greenwich.

3546. Have you noticed whether it has got higher than that since then?—Yes; it is up at our Limehouse entrance of the south dock, and that is as far as my observation goes. I have no business any further.

3547. (*Mr. Beaumont Morice.*) That is a considerable way higher than it came in 1879?—Yes.

Cross-examined by Mr. Bidder.

3548. You are dock-master, I understand?—I am the principal dock-master.

3549. I should like to know where your house is that you speak of, and that you say is close to the river?—Close to the Blackwall entrance to the West India Dock.

3550. Would you mind pointing it out on the map?—Just here (*pointing to the map*).

3551. I understand you to say that not only is the sewage poured in at Barking, but that sometimes, when there is an accident to the pumping station at Barking, they turn it into the Lea?—Yes, that is what I say.

3552. You say that, of course, because you know it is a fact?—Yes.

3553. You are quite certain of it?—Yes.

3554. Should you be surprised to hear that there is no pumping station at Barking?—I did not say at Barking; I said at Bromley. We call it the Barking outfall; I do not know whether I am right in the term; it may be at Barking, but we call them the Barking outfall and the Crossness outfall.

3555. You certainly said, when there was an accident at Barking Pumping Station?—Well, at the Barking outfall; that is the name it goes by in the river.

3556. You do not mean anything at Bromley?

3557. (*Chairman.*) You said that when there is an accident at the Barking outfall some pumping takes place at Bromley?—Yes, at Bromley; that is the overflow pumping station.

3558. (*Mr. Bidder.*) What kind of accidents happen at Barking?—I do not know what kind of accidents they are. I know there was a stoppage at Barking at that time, and I can assure you that it came into the East India Dock in one solid mass of sewage; for I was there.

3559. Not liquid?—Yes, liquid of course, or else it would not flow.

3560. The Lea comes into the river close below your dock entrance, near your house?—Yes.

3561. Are you aware, or can you tell the Commission, whether as a matter of fact the sewage of all West Ham and Stratford is discharged into the Lea near its mouth?—I do not know for a fact.

3562. Do you see on the map places labelled as West Ham outfalls?—Yes.

3563. Are you aware that there are outfalls there?—No.

3564. You never heard of that?—No; I do not know where it would go to.

3565. We can all form a judgment where it would go to; but you personally know nothing about that?—No.

3566. I understand you to say that until the year 1879 a very moderate quantity of dredging sufficed to clear your dock?—Just as much as we could do.

3567. 69,000 tons?—Yes.

3568. And this year you have had practically more than double that quantity to deal with?—Yes. I did not say that it was all sewage, you understand.

3569. I did not ask you that question. You attribute that, I understand, to the sewage having come up from the outfall?—Yes, a good part of it.

3570. Then of course you mean us to understand that all the increase is due to the sewage?—No, I do not.

3571. Then what is it due to?—It is due, this year especially, partially to the sewage, but partially to the large number of heavy tides that we have had this year, bringing down a lot of land water and mud with it.

3572. There is no doubt that a great deal of mud has been brought down by that?—No doubt about it.

3573. It has been very exceptional this year?—Very exceptional.

3574. You said that it took $2\frac{1}{2}$ years to come up to that from Barking?—No, I do not think I said that. From one entrance to the other I think I said; from the Blackwall entrance to the Limehouse entrance, because I said I had no knowledge of it below.

3575. Then you account for that, as I understand you, by the fact, if it is a fact, that the flood tide is practically stronger than the ebb?—Yes.

3576. So that the sewage which is put in at Barking, though it is carried down towards the sea, comes up more than it goes down?—Yes.

3577. And in process of time works its way up the river?—Yes.

3578. And whatever is put into the river at Barking or Crossness gradually works its way up the river?—Yes.

3579. And that has been going on ever since the outfalls were opened?—Yes.

3580. Always working up little by little?—Yes.

3581. And, of course, accumulating in the upper part of the river?—Yes.

3582. Whatever has been put in at Barking or Crossness since the outfalls were opened?—Yes.

3583. When you tell the Commission that it took $2\frac{1}{2}$ years to come up to your entrance, and that now it has got up to Limehouse, I want to know the exact point that you mean it has got up to at Limehouse?—I mean that there is a proportion of sewage which has got up to Limehouse.

3584. You said that you recognised last week that it had got up to Limehouse?—That was not the first time I tested it.

3585. (*Chairman.*) You said that you had seen the sewage as far up as Limehouse, and that you tried some there a week ago; but you did not say that that was the first time you had seen it?—No.

3586. (*Mr. Bidder.*) How do you ascertain the fact of its reaching up as far as Limehouse?—By testing the mud, by smelling it, and by the feel. It has a different feel altogether from common mud; it feels slimy and greasy.

3587. That is what I am to understand you to mean when you say that you recognise the sewage, whether at your own docks at Limehouse or anywhere else, that you feel the mud and it feels greasy and slimy, and that you smell it and it smells bad?—Yes. I did not taste it.

3588. You also went further as regards the mud in your docks, and you spoke of the proportion of sewage mixed with the mud being large; how have you ascertained that?—By the colour of it.

3589. Is it lighter or darker?—Darker. It turns the mud black.

3590. What used to be the colour of the mud in your dock?—Sand colour.

3591. Is it now black?—It is black when it is stirred; when we raise it.

3592. And as to anybody suffering, you said very fairly that you had only heard of one man suffering, and that that was not within your own knowledge?—That is so.

3593. Have you men stationed down at Crossness?—Yes.

3594. I think you have a place where you shoot the mud?—Yes, adjoining the pumping station at Crossness.

3595. How many men have you stationed there?—I do not know. It is under the inspector of mudding. I think there are about 12 men.

3596. Do they live there?—Yes.

3597. And are those men employed for the purpose of barging down your mud; is it their business to go up and down to and from that place?—No; they are stationed there.

3598. Do they live on shore?—They live on shore.

3599. I think that place adjoins the outfall station at Crossness?—Yes.

Re-examined by Mr. Beaumont Morice.

*Capt. J. Hussey.*

22 Nov. 1882.

3600. Has there been any solid matter in this sewage that you have noticed above your entrance?—I take it up in my hand and feel it and smell it.

3601. But is there any solid matter in the sewage in the water; is the water thick, or is it clear?—The water is very thick. Of course, that is a great deal attributable to the large number of steamers that have been employed lately.

3602. (*Chairman.*) In point of fact, the water is thick?—Yes; it comes in very thick.

3603. (*Mr. Beaumont Morice.*) Have you ever noticed any lumps in it?—I have not.

3604. And it is because you have had to dredge it out that you speak about this increase of mud and sewage?—Yes.

Examined by the Commission.

3605. (*Chairman.*) You said that the mud in the dock was formerly sand colour?—Yes.

3606. When did it cease to be sand colour?—The first time I began to observe it was about the year 1876; but I did not take any particular notice of it till about the year 1879.

The witness withdrew.

Mr. George Frederick Fuller called in, and examined by Mr. Beaumont Morice.

*Mr. G. F. Fuller.*

3607. I believe you are a member of the firm of Messrs. G. and A. Fuller?—Yes.

3608. And I think your firm are dredging contractors to the Government?—Yes.

3609. Have you been in the habit of dredging for ballast in the River Thames?—Yes, for the last 20 or 30 years, for ballast and sand.

3610. In what part of the river have you been dredging?—From Woolwich to Gravesend.

3611. In the early part of the time, say 20 to 30 years ago, what did you get from the bed of the river?—We used to get clear sand, building sand, and ballast, at what they call Jenningtree Point.

3612. And at any other places?—At all the points down the river. There are six or seven other points between there and Gravesend. Fiddler's Point is the last one before Gravesend. The sand accumulates around each point when there is a tideway.

3613. May I take it, then, that practically at each point down the river you obtained sand?—Yes; we used to get it as near London as possible; but eventually we were driven right down, and we have now to go to Coalhouse Point, below Gravesend.

3614. Up to what time were you able to get sand at Jenningtree Point?—We began there.

3615. When did you cease?—Soon after the sewers were opened; I should think the first year after. In 1866, or something like that; we ceased to dredge at Jenningtree Point after the sewer was opened on the Crossness side.

3616. Where did you go to then?—To the next point. I forget the names; there are six or seven of them. Tripcock Point, I think, is the next one.

3617. That is opposite Barking?—Yes; they drove us down, year by year.

3618. When did you go away from there?—I cannot say exactly.

3619. (*Mr. Bidder.*) Tripcock Point is higher up the river than Jenningtree Point?—Tripcock Point is the first point; it is higher up than Jenningtree Point. We began at Tripcock Point.

3620. You said just now that you left Jenningtree Point and went to Tripcock Point?—The first point below the entrance below Woolwich is Tripcock Point.

3621. (*Chairman.*) You used to dredge at Tripcock Point. When did you leave it?—About 12 months after the Crossness entrance was opened.

3622. Then you went to where?—We went to the next point, that is Jenningtree Point. We worked at both those points at the same time, and then about 12 months or so after the entrances were opened for the sewage we had to get further down.

3623. Were you obliged to leave both the points at about the end of the year?—Yes, at about the end of the year. There are so many points that I confuse them.

3624. Having left Tripcock and Jenningtree Points, where did you next go to?—We came down to Coldharbour Point then.

3625. That is on the other side of the river, is it not?—Yes.

3626. (*Mr. Bidder.*) Is Coldharbour Point the point opposite Erith Bight?—Yes.

3627. Is that where you are now?—No; the Coalhouse, below Gravesend.

3628. (*Mr. Beaumont Morice.*) How long did you stay there?—They used to go and come, if I may explain it. Sometimes, when there was a good sluice of water down, a lot of water down from the upper river, there used to be sand that would last one, two, or three freights, and they would work that away and then go away again.

3629. (*Chairman.*) When were you first obliged to desert Coldharbour Point?—Three or four years ago, I should think.

3630. For three or four years afterwards you were able to work there unintermittently?—Yes, you might say that, until we were driven away.

3631. Then afterwards you were able to come back occasionally when a heavy flood brought down sand from the country?—Yes; when there was a good flush out it seemed to leave two or three freights of sand, and the men would work that away.

3632. But for three or four years after going down to Coldharbour Point you were able to work there unintermittently?—Yes.

3633. Why did you leave that place?—Because we were driven away by the mud. Customers complained of the filth in the sand.

3634. (*Mr. Beaumont Morice.*) Then after three or four years where did you go?—To Crayfordness.

3635. That is on the south side?—Yes.

3636. When had you to go away from Crayfordness?—I worked, on and off, at Crayfordness for about 10 years. That somehow clears itself in some way.

3637. Crayfordness is the point below Erith, is it not?—Yes.

3638. Do you remember the year that you had to go away from there?—That is something like the other point. They can come back again and get a little there.

3639. (*Chairman.*) Down to the present time?—It is very dirty now.

3640. Do you ever go there now?—No; they will not accept it now.

3641. When did you cease altogether to go there?—We are not supposed to have got any sand from there these last two or three years.

3642. Where did you go to after that?—To Fiddler's Point.

3643. And when did you leave Fiddler's Point?—Within the last few years we have been driven down to Gravesend. Within the last four or five years we have got our sand between Fiddler's Point and Gravesend and Coalhouse.

3644. (*Mr. Beaumont Morice.*) Coalhouse is on the north shore, just beyond Gravesend, is it not?—Yes.

3645. (*Professor Williamson.*) Where is Fiddler's Point; is it opposite Greenhithe?—Yes.

3646. It is marked here "Stoneness"?—Yes, but

we have a name for the Point, and the men know it better by that name. It is called Fiddler's Reach. I am giving you rather the name that the men call it by, if we ask them where they get it from.

3647. (*Mr. Beaumont Morice.*) You say that you found the sand mixed with filth; will you tell us exactly, or as nearly as you can, in what way the filth lay on the sand?—The men had to wash it.

3648. (*Chairman.*) Did you see it yourself?—Oh yes; it is brought back to us, sent home in sample.

3649. In what condition did you find the sewage; was it mixed with the sand?—Yes, it was intermixed with the sand. You can smell it as well when it is dry, and it discolours it and turns it black.

3650. (*Mr. Beaumont Morice.*) Have you seen it brought up by the dredgers from the bed of the river?—Yes, we have it in our barges daily.

3651. What was the condition of the buckets or bags which brought up this stuff?—They have it in a large bag, and they lodge the bag, and they allow as much muck as they possibly can to run over the edge of the bag before they tip it into the barge's hold; and that is all filthy black stuff.

3652. The top of the bag is full of filth?—The top of the bag is full of filth; and they allow the thing to squeeze itself down, and the best part of the muck to run over.

3653. And you say that there is a smell from it?—Yes; it is very unpleasant indeed.

3654. Has that been the case at the different points down the river?—Yes, always the same as we have been going down. It got so bad at last that we were obliged to leave the different places. The customers would not have the sand, and therefore we were obliged to go lower down. It was only reported yesterday that the Gravesend sand was spoilt now.

3655. (*Chairman.*) Did you see it yourself?—No; but one of our men reported yesterday that the Gravesend sand was covered with filth to a depth of 18 inches.

3656. (*Mr. Beaumont Morice.*) Do you know, beyond what you have told us, the condition of the river in the upper part by Woolwich lately?—I know the condition outside both the outfalls.

3657. Do you know the upper part by Woolwich at all?—Our own premises are at North Woolwich. We have got about 1000 feet of frontage at North Woolwich, and that is in a dreadful state; it is covered with about 18 inches of this filthy stuff. That has accumulated in the last 18 months or two years; it seems to have got there since 1879, I think it was, when we took the place. In two or three years 18 inches of mucky, filthy brown or browny-red stuff has accumulated. The top of it is covered with a light brown sort of material.

3658. Is there any smell to it?—Yes, of course it smells; but I do not know that you would smell it now unless you took it up in your hand; but in the summer time it is awful.

3659. Is it different from the ordinary mud?—Yes, it is a different colour; it is a reddy-brown.

3660. Would you call it mud?—No, I should not.

3661. What should you call it?—Sewage.

3662. (*Mr. Bidder.*) Eighteen inches of sewage?—I do not say that there are 18 inches entirely sewage. The stuff is mixed with the mud, but it is coated with a light coat of sewage on the top of it.

3663. (*Mr. Beaumont Morice.*) Have you been in the habit of using this Thames water for the purposes of your business; for cranes and things of that kind?—Yes, for crane boilers; but we have been obliged to stop that within the last two or three years; we cannot use the Thames water for boiler purposes.

3664. Why have you had to stop it?—The water is so filthy.

3665. (*Professor Williamson.*) But what effect does that produce?—It makes the boilers prime, and it adheres to the tubes, and so burns the tubes out.

3666. (*Mr. Beaumont Morice.*) What have you had to do in consequence?—We have been obliged to have the water company's water laid on.

3667. That is an additional expense?—Yes, rather a large expense, because we are out of the way of the water, and we have had some thousand feet of pipe laid there.

3668. Have you ever suffered any injurious effects to your health from this sewage?—For two summers I was very poorly over it; both in July of 1880 and in July of 1881, when the temperature was so high; it was 97° at times in those months, and then the smell was very bad, and it affected me because I was there a fortnight.

3669. In what way did it affect you?—With sickness.

3670. Have you ever had any barges sunk in the river?—Yes, rather too many.

3671. The reason why I ask you that question is this: in getting them up again, in what state did you find them?—There is always a bad sediment on them above Gravesend, perhaps half an inch in a day or 24 hours.

3672. What is the sediment, so far as you can say?—Mud and sewage mixed together.

3673. You say that is above Gravesend. Have you ever had any experience below Gravesend?—Yes, we have had two or three below Gravesend; but we do not find the filth in the sunken barges below Gravesend that we do above Gravesend.

3674. Do you have any difficulty in getting men to attend to them in consequence?—Yes; they seem to require a good deal of refreshment before they will have anything to do with it.

3675. (*Mr. Bidder.*) Do you mean when they are raising barges?—No, when they are throwing muck out.

3676. (*Mr. Beaumont Morice.*) Do you find more difficulty in getting men for the work above Gravesend than below?—Yes.

3677. On what ground?—On the ground of the filth and the smell of the stuff.

Cross-examined by Mr. Bidder.

3678. You appear to carry on two businesses as I understand, dredging sand and dealing with mud?—Yes, they are two distinct businesses.

3679. You have spoken about barges above Gravesend being covered with mud and filth; are you old enough to remember the river before 1864?—Yes.

3680. Was there no mud in the river then?—Yes, but it was a different kind of mud; it was a whitey mud, as far as I can remember it, then.

3681. It did not smell at all?—No.

3682. And in your experience of the river before that date there were no offensive smells at all?—I will not say that; I say the water was very bad at times in very hot summers before the sewage came there. Sometimes the water was very bad and black.

3683. By-the-by, while it is in my mind, what was the nature of your illness which you spoke of in the summers of 1880 and 1881?—Sickness and unpleasant feelings. It turned my stomach, in fact, and I vomited.

3684. Where do you reside?—At Granville Park, Blackheath, but I am almost all day on the water.

3685. As regards the dredging at Jenningtree and Tripcock Points, as I understand, you were driven away from there because the mud came in those parts of the river where you were accustomed to get sand?—Yes.

3686. In point of fact, those are the mud banks that have been spoken about; one of them is right opposite the Crossness Reservoir, is it not, extending up to Jenningtree Point?—Yes.

3687. And the other one above Jenningtree Point?—Yes.

3688. And then there is a third one in Erith

*Mr. G. F. Fuller.*

22 Nov. 1882.

Bight?—Yes; and there is another very large one at Grays. We had a barge sunk last week, or a fortnight ago and they put her ashore in four feet of mud for us and that was a clean hard shore a few years ago. That is new to me.

3689. Whatever caused those mud banks has driven you away from those places?—Quite so.

3690. You said that as regards Crayfordness you went there, off and on, for some years, and you said the same of Coalhouse Point, I think?—Yes; when a flush has come down it has seemed to clear the muck off for a time.

3691. But there is another thing, is there not; it depends upon the tides whether the sand comes up and accumulates; the sand of course comes from seaward, does it not?—I do not think it does; I think it comes down with the wash.

3692. But it fluctuates, and always did fluctuate, and sometimes you have more sand at the points and sometimes you have less?—Yes, it would fluctuate no doubt.

3693. Do you think that the increasing traffic of the river, and the constant stirring up of the mud, has had anything to do with the additional dirt in the water?—No, because we have eight or nine feet of mud where we used to get clean good sand.

3694. You are again referring to the places that I have already mentioned?—Yes; the two or three upper points seem to be the worst.

3695. With reference to your place at North Woolwich, you say that there you have 18 inches of mud, which you call sewage, and you afterwards added that you do not mean that it is all sewage?—No, it is mixed.

3696. Did I rightly understand you to mean that there was a coating of sewage on the top?—Yes.

3697. How do you identify that?—By the colour.

3698. What is the difference in the colour?—Mud has a kind of white appearance at the top; the sewage is a reddish brown.

3699. They are of different colours. Now about the water in the boilers; can you tell me what water the river steamers use for their boilers?—Yes; but they have condensing engines; they condense their water; they use condensers.

3700. Do you know what water they use?—Thames water.

3701. (*Professor Williamson.*) Do you mean that they use surface condensers or injection condensers, because they are quite different things?—They use both. They use clear water to put into the boilers; they do not use this filthy water out of the river to go into the boilers; it would wear their boilers out in a very short space of time.

3702. Do you know that a great number of them use surface condensers, by means of which they can return distilled water to the boilers; I know that a great number of them do.

3703. (*Mr. Bidder.*) How long have you occupied these premises at North Woolwich?—Since the year 1879; and 18 inches have accumulated there since we took them in 1879.

Re-examined by Mr. Beaumont Morice.

3704. Since 1879 there has been that accumulation?—Yes.

3705. With regard to the mud at the two points that you have been asked about, does not this mud apply to all the points that you have mentioned?—Yes.

Examined by the Commission.

3706. (*Colonel Ewart.*) Did you say that you supplied building sand to a large extent?—Yes.

3707. Then for that purpose you want fresh water sand?—Yes.

3708. Has the cost of the sand been altered by the distance that you have to go to get it?—Yes.

3709. The cost has increased, has it?—Yes.

3710. Then again, do you have any questions raised about the saltness of this sand if it is used for building purposes?—Yes, we do unfortunately.

3711. Has there been any question raised in consequence of your having gone lower down?—Yes; they prefer the salt to the sewage in the sand.

3712. But if you go down to those points below Gravesend, would you not get a larger amount of salt in your sand for building purposes?—Gravesend sand is very free from it in some way; they get it at the last of the tide, and at the tearing down of the upper water you have fresh water coming down. We can only get this sand at ebb tide, and therefore no salt water runs over the Gravesend sand; it is purified by the fresh water running over it.

The witness withdrew.

Captain Michael Williams called in, and examined by Mr. Beaumont Morice.

*Capt. M. Williams.*

3713. I believe you are captain of the "Goliath" dredger?—Yes, I am.

3714. Where?—In Long Reach.

3715. How long have you been there?—Three years. I have not been in Long Reach three years; I have been in Long Reach a year and a half; previously to that I was in Erith Reach.

3716. You have been dredging?—Yes.

3717. What have you been getting up?—Ballast.

3718. What sort of stuff have you been getting up?—We are getting good gravel now; but at times we have found a great deal of soil, particularly just astern or lower down from the training ship "Cornwall."

3719. (*Chairman.*) In Long Reach?—Yes; just astern of the training ship "Cornwall" we have found it from eight inches to a foot thick.

3720. For the last year and a half?—For the last 12 months we have had it.

3721. What were you dredging for?—For gravel for ballast.

3722. When did you first find any mud, as you call it?—Just in the middle of last summer.

3723. (*Mr. Beaumont Morice.*) Whereabouts in Long Reach does the "Cornwall" lie?—Very near to the higher end of it, right opposite Purfleet.

3724. That is the top of the Reach?—That is very near the top of the Reach, opposite the village of Purfleet.

3725. How long did you remain there getting up this soil?—We did not stop long at that, because that is not what we required.

3726. Where did you go to then?—Then we moved farther off to get some better ballast.

3727. (*Chairman.*) Where did you move to?—Farther out in the river, but in the same neighbourhood.

3728. Did you move 100 yards away?—No; perhaps not 100 yards, but very nearly 100 yards.

3729. Fifty yards?—Fifty yards; just as we found it necessary.

3730. You moved about 50 yards away?—Yes.

3731. Did you find it all right there?—We found it better.

3732. Did you find any mud when you moved the 50 yards?—I cannot say rightly now, to be positive.

3733. Did you remain there till the present time?—We shifted to different places.

3734. Why did you shift?—When we shift sometimes it is dirty, and sometimes the gravel has been all taken up.

3735. (*Mr. Beaumont Morice.*) Why did you shift

about so much?—Sometimes when we lowered the ladder down to get ballast, if you understand it, we have frequently just astern of the training ship "Cornwall" found it dirty; that is quite sewage.

3736. Then you went more out into the stream?—Yes, where the current of water is running strong, and that keeps the gravel cleaner, because it washes it.

3737. I understood you to say that you left Erith Reach because of the mud?—Yes, it got so thick that we could not do anything with it. In some parts of Erith Reach, for instance, in the upper part of it near the coal hulk, I should think it is very nearly 2 feet thick, nothing but sewage matter; so that it was not at all profitable work, and sometimes it was very offensive.

3738. In dredging in Long Reach, are you obliged now to go into the strength of the stream?—We are in a great measure, to have it clean.

3739. Since you have been dredging, has there been an increase of this mud and stuff on the banks of the river?—Yes. I have not been many years at it; but in the little time that I have known it there has been an increase.

3740. Is that mud, or is it anything different from mud?—It is sewage matter, I should think; it is very offensive; when it is stirred up you can hardly endure it.

Cross-examined by Mr. Michael.

3741. Will you point out to me on the map behind you where the sewage matter is?—I cannot say that I can see that clearly.

3742. Is it on the Erith side or on the other side?—I think all the way down the Erith side is full of mud.

3743. I understand that you have been three years engaged in dredging?—Yes.

3744. During that time have you noticed the mud increasing in Long Reach?—That is a question that I can hardly answer.

3745. (*Chairman.*) I understood you to say that you had been only a year and a half at Long Reach?—I have been about a year and a half in Long Reach, and about a year and a half in Erith Reach.

3746. (*Mr. Michael.*) You have been for three years engaged in this portion of the river; is that so?—I have been engaged for three years in the river.

3747. Have you been noticing the increase or otherwise of mud in this part of the river between Erith and Long Reach during the last three years?—That is a point upon which one can hardly answer yes or no.

3748. (*Chairman.*) Have you noticed any increase?—I think it is increasing.

3749. Have you noticed it?—I cannot say that I have noticed it.

3750. (*Mr. Michael.*) Then you have not noticed, one way or the other, whether it is increasing or no; is that so?—That is it.

3751. On either side, whether at Purfleet or Erith?—I am quite satisfied that in Erith Reach it greatly increased during the little time that I was there.

3752. Is that in the last 18 months, or in the 18 months before that?—In the 18 months before that.

3753. Then in the 18 months before the last 18 months you noticed that the mud was increasing at Erith?—Yes.

3754. How much ballast do you take up in a boat a week?—I do not think that is the question, if you will excuse me.

3755. That is the question I put to you. How many tons of ballast do you ordinarily take up in a week in a boat?—We take it in barges. I should say that we average about 3000 tons per week; but it varies.

3756. How many boats will be engaged in order to get the 3000 tons?—Some boats will take 20 tons, and others will take 150 tons, so that it is difficult to say.

3757. Are you always engaged in one boat?—I am the captain of the dredger.

(*Mr. Beaumont Morice.*) I do not think it is a question that it is possible for the witness to answer.

3758. (*Mr. Michael to the witness.*) What is the tonnage of the dredger?—I could not say.

3759. What is the horse-power of it?—About 30 horse-power.

3760. How much does the dredger raise in a week?—I told you I should say about 3000 tons, but it varies; it depends upon the customers who come. Sometimes we may have a good many barges.

3761. Is that the dredger in which you are engaged?—Yes.

3762. How many dredgers are there at work getting ballast?—That is not for me to answer.

3763. Do you know or not?—I do not know.

3764. What is the name of your dredger?—"Goliath."

3765. Do you know the names of any others?—Yes, there is one called the "Hercules," belonging to the same corporation that I belong to.

3766. (*Mr. Abernethy.*) 3000 tons is very moderate work for a dredger, is it not?—It is a very good week's work.

3767. (*Chairman.*) Is it necessary to pursue this in detail?

(*Mr. Bidder.*) It is a material point in our case, though I cannot disclose at the moment what the materiality of it is. It is not a question of the credibility of the witness, but we want the fact for a reason of our own.

3768. (*Chairman to the witness.*) Your own dredging vessel is the "Goliath," and it dredges 3000 tons?—I do not know that I should be right to say how much business we do do, but I should say about 2000 to 3000 tons a week.

3769. The question put to you is whether you know the other dredging machines?—Yes, several.

3770. Will you give Mr. Michael the names of those machines?—There is the "Hercules," belonging to the same corporation as I belong to; that is one. Then there is the "Bee," belonging to Mr. Williams. Then there is another, called the "Ant," belonging to the same person. That is all that I could say. I believe the Conservancy have two or three, but where they are employed I could not say.

3771. (*Mr. Michael.*) Those four are employed in Long Reach?—Yes.

3772. Are they of the same power as yours?—I could not say that. I do not know what power they are.

3773. And you cannot tell me about how much they raise per week?—I should think about the same as ours, and perhaps rather over.

Re-examined by Mr. Beaumont Morice.

3774. I understand that you raise the stuff according as customers come for it?—Yes; it is just like a grocer's shop; if many customers come we serve them, and if they do not come we do not sell anything.

3775. Therefore you may raise more one week than another?—Yes, and we very often do. Sometimes we raise 5000 or 6000 tons a week.

Examined by the Commission.

3776. (*Dr. Stevenson.*) You say that you went further out into the river; are you allowed to go as near as you like to the shore when you are dredging?—We are not. We have restrictions as to how near to go to the banks of the river. There are two points lately put up, and at first we had an order to keep 300

*Capt. M. Williams.*

22 Nov. 1882.

feet away, and now we have had an order just issued to keep 900 feet away.

3777. Then you are not allowed to go so near in as you were formerly?—No; that is the place where we want to get.

3778. Had those restrictions anything to do with your going further out into the river?—Yes, partly. At one time we had no restrictions at all.

3779. (*Chairman.*) Who imposes those restrictions? This order is issued from the Conservancy.

3780. (*Dr. Stevenson.*) Do you know why they imposed those restrictions?—They thought we were damaging the embankment.

3781. Has it given way at all?—It has been giving way for all time, from what I can learn. They have been repairing it for many years.

3782. But had it given way during the year and a half that you were working there?—No, not to my knowledge, although they say it has; but we think it has not.

The witness withdrew.

Captain Joseph Richard Whitehorn called in, and examined by Mr. Beaumont Morice.

*Capt. J. R. Whitehorn.*

3783. I believe you are captain of the "Hercules" dredger?—Yes.

3784. How long have you been there?—I have been on board 27 years.

3785. Where is she dredging now?—Between Greenhithe and Purfleet.

3786. For how long have you been dredging there?—For six months past.

3787. That will be in Long Reach?—Yes.

3788. Where were you dredging before that?—In Erith Reach.

3789. How long were you dredging there?—We have been on and off there for about 10 years.

3790. What used you to dredge for?—Gravel.

3791. Why did you leave Erith Reach?—On account of the badness of the stuff, the material coming so bad.

3792. (*Chairman.*) What do you mean by "bad"?—Soft stuff that came up. With a bucket of gravel we should have a quantity of sewage matter, as we term it.

3793. (*Mr. Beaumont Morice.*) Will you tell the Commission how you noticed that there was sewage amongst the gravel?—The lightermen will not take it if there happens to be any bad stuff in it. It must be all clean gravel, because it is for concrete purposes.

3794. (*Chairman.*) You do not know anything about it, but you merely judge from what the lightermen say?—We see it coming up in the buckets, and we take it out of the buckets with a spud and smell it.

3795. You smelt it and saw it?—Yes.

3796. And from your eyes and from your nose could you form any judgment as to what it was?—We attributed it to the sewers, and to nothing else. We never had it before the sewers came there.

3797. You believe it was sewage matter?—I believe it was sewage matter.

3798. (*Mr. Beaumont Morice.*) What was the colour of it?—Very black.

3799. Was it different from mud?—Yes, quite different from mud.

3800. Was there any stench with it?—Yes.

3801. Was it in any particular part of the bucket that it came up; was it mixed with the sand?—It was all mixed with the sand.

3802. Then you had to go from Erith Reach?—Yes, to shift away down till we came to cleaner stuff, to Long Reach, to Purfleet, where a greater rise of tide would keep the ground cleaner. We used to work opposite the sewer at one time in Halfway Reach.

3803. You say that you worked at Erith for 10 years?—Yes, on and off.

3804. It is only six months since you came into Long Reach?—The stuff was so bad that we had to shift.

3805. You worked at Erith for 10 years up to within the last six months?—Yes, and in Half-way Reach as well.

3806. In whose service are you and the last witness?—In the service of the Trinity House.

3807. You have been dredging for 27 years, and therefore you knew the river before the outfalls were opened?—Yes.

3808. Where were you dredging before the outfalls were opened?—Above the sewer in Barking Reach.

3809. What did you get there?—Very clean stuff; it was rather fine sand, but it was very clean. There was no mud with it.

3810. When did you have to go lower than Barking Reach?—About eight years back.

3811. But you have been 10 years in Erith Reach?—We come up and down to try the stuff. We do not always stop in one place.

3812. (*Chairman.*) The question is, when did you leave Barking Reach for good?—Perhaps 12 or 14 years ago; but we have worked up and down, and kept shifting about during the time that I have been on board the vessel.

3813. (*Mr. Beaumont Morice.*) Then you were working in Erith Reach, and I suppose down Erith Rands, for about 10 years?—I daresay I was.

3814. In what part of Long Reach particularly are you working now?—On the south shore, about halfway down, off Little Powder-monkey Creek.

3815. Have you any difficulty in getting sand there now?—No, we have got a bit of ground there now.

3816. How far up the river can you go to get gravel at the present time?—I do not think we should find anything above Erith, not to say good clean gravel now.

3817. (*Mr. Bidder.*) Have you tried?—Yes.

3818. (*Mr. Beaumont Morice.*) You have been trying, I understand, for 27 years altogether?—Yes, on and off.

3819. (*Chairman.*) When did you try for the last time up in the direction which the learned counsel is asking about?—Between two and three years ago, as well as I can recollect.

3820. Where did you try then?—At Dagenham.

3821. With what result?—It was no good at all. It was all mud and sewage with it, and we had to leave it and go away again.

3822. Was it like ordinary mud, or what was it like?—It was very soft stuff, and not exactly like the mud you would see in the streets; it is of a bluish cast, and very soft, and it does not smell very nice either. It is a different kind of mud from what you see on the shore.

3823. What do you mean by its not smelling very nice?—In the summer time we worked off the sewer, and we smelt the stuff.

3824. When you say that it did not smell very nice, do you mean that it smelt like sewage?—Yes.

3825. (*Mr. Beaumont Morice.*) Will you give us in your own words what sort of a stench it was that this stuff smelt like?—On a summer's morning I have been on deck and I have had to go below when the sewage matter has been coming out from the sewer; and it has been quite as black as ink, with a faint smell.

3826. Has there been anything of a similar smell about the muck that you got up with the sand?—Yes, it is similar; you can tell it directly. We have had so much of it that we know what it is.

3827. You have no doubt about it?—I am sure of it.

Cross-examined by Mr. Bidder.

*Capt. J. R. Whitehorn.*

22 Nov. 1882.

3828. As I understand, the times when you have smelt it badly and have had to go below have been when you have been moored opposite the outfall?—Yes, or at Barking; anywhere near there.

3829. You do not cruise about very much with your dredger; you are usually moored somewhere?—Yes.

3830. And when you were dredging at Dagenham you were just opposite the outfall?—Yes.

3831. When the sewage was discharging close to you it smelt strong and faint?—Yes; it was high water, and we were not dredging at the time.

3832. I did not say you were. Do you go and dredge wherever you like?—No.

3833. Who settles where you are to go and dredge?—The Thames Conservancy.

3834. You were mainly in Half-way Reach for 10 years?—Yes, there and in Erith Reach combined.

3835. You could not be in two places at once. You were working in Half-way Reach, you told us, for 10 years and then you went to Erith Reach?—Yes.

3836. During those 10 years, I presume that you dredged a very large quantity of stuff in Half-way Reach?—Yes.

3837. What is the capacity of your dredger?—We average 2000 tons per week at the present time.

3838. Is it not the fact that where you were dredging in Half-way Reach was at a place called Dagenham Shoal?—Yes.

3839. And that, until about 15 or 16 years ago, or more, was a shoal that contracted the channel and the depth of the river?—Yes, it would do so.

3840. And I think the Conservators cut off the hard cap of the shoal that prevented the ordinary dredger being able to touch it?—Yes.

3841. And after they had done that the dredgers set to work?—Yes, so they did.

3842. Were there other dredgers at work at it besides the "Hercules"?—Yes, the "Thorpe," the "Sampson," and the "Goliath." They were all work-in the reach at that time.

3843. And they were all engaged for the best part of that time on that shoal?—No; the "Thorpe" was not there very long.

3844. But the other three were there steadily?—Yes; not in one spot, but in the reach.

3845. At the end of the 10 years, where there had been a shoal you had dredged a very deep hole, had you not?—Yes, of course we had.

3846. How much deeper did you make that part of the river than it was when you began?—We would make it something like 28 or 29 feet deep.

3847. Do you mean 28 or 29 feet at low water?—Yes.

3848. What was the depth of it when you began?—About 22 feet to 24 feet more or less.

3849. It was not so much as that on the shoal, was it?—Not on the top of the shoal, but the Conservancy moved that away.

3850. The depth of water over the shoal was not above 13 or 14 feet, if I recollect rightly?—It was more than that; it was about 16 feet.

3851. And then on each side it shelved down, and your dredgers cleared away the whole of this, and got a depth of 28 or 29 feet, and then the mud began to collect?—It would not have done so if the sewer had not been there.

3852. And then the mud began to deposit?—It naturally filled in.

3853. Now then I will take you down to Erith; were you employed at Erith also, at a place called Erith Rands?—Yes.

3854. Is that a shoal that used to exist off the point on the north side of the river, opposite Erith Bight?—Yes, there was a shoal there called the Rands.

3855. (*Mr. Beaumont Morice.*) That is below Erith though?—Yes, it is below.

3856. (*Mr. Bidder.*) Perhaps I have got the wrong name, but there was a shoal opposite Erith Bight at Coldharbour Point?—I do not know of one there, only Erith Rands; not to say a shoal.

3857. Will you put your finger upon the place where you mainly dredged at Erith?—There (*pointing it out*).

3858. There was a shoal there, was there not?—Not that I know of. We never saw much of a shoal in Erith Reach.

3859. (*Chairman.*) But you dredged there for a number of years?—Yes.

(*Mr. Bidder.*) Being a marine captain you understand a chart; look at the Admiralty chart (*handing a chart to the witness*). Do you mean to say that you did not know that there was a shoal at that place on the Admiralty Chart?

(*Mr. Beaumont Morice.*) There is a little spit running out; that is what my learned friend means, I think.

3860. (*Mr. Bidder.*) I prefer to call it a shoal. (*To the witness.*) Calling it whatever you please, there was a place there where the bed of the river was shallower than the rest of it?—In places all over the river.

3861. But I mean in this particular place where you dredged; and you dredged that entirely away, did you not?—Yes, we should take it away as we came to it.

3862. You did take it all away?—I cannot say that we took it all away. If the stuff was not good we should not take it.

3863. (*Chairman.*) You did take away a quantity of stuff?—I cannot say that we took it all away; we may have left some.

3864. But you did take away a great quantity of material from that place?—Yes, we have done so.

3865. How long were you dredging round that place?—We would go a certain distance, and come back again. We were dredging there for 8 or 10 years, as far as I can guess.

3866. Then for 8 or 10 years you were dredging all round that point?—Yes.

3867. (*Mr. Bidder.*) That was at Dagenham, was it not?—All the way down, because we work down a reach and then go up again.

3868. (*Chairman.*) I asked you how long you were dredging upon the portion that you pointed out to the learned counsel?—About 8 or 10 years. I have been 27 years on the ship between Woolwich and Erith. We do not stop in one place.

3869. (*Mr. Bidder.*) Will you point to the different places in that reach down to Erith where the water was shoal?—Where the gravel was clean; we go wherever we find the stuff clean; we do not go for shoals.

3870. At Erith was the result of your dredging to greatly deepen and widen the channel on the north side of the river?—We did do so unquestionably.

3871. And all the way up on the north side as far as Dagenham?—Yes, on account of the gravel being cleaner on that side.

3872. (*Chairman.*) I suppose we shall get this accurately from a comparison of the charts?

3873. (*Mr. Bidder.*) At the proper time we will give it you. (*To the witness.*) You work for the Conservators, do you not?—No, for the Corporation of the Trinity House.

(*Mr. Beaumont Morice.*) I am informed that as a matter of fact the Conservators do not tell the Trinity dredgers where to go.

3874. (*Mr. Bidder to the witness.*) You said just now that the Conservators tell you where to go?—If we get too near the shore they find fault with us. We are under the jurisdiction of the harbour-master.

(*Mr. Lumley Smith.*) If they get too close to the shore they are warned off.

3875. (*Chairman to the witness.*) You are an officer of the Trinity House, and if you encroach upon the domain of the Conservancy, the Conservancy and their employés will warn you off?—Yes.

*Capt. J. B. Whitehorn.*

22 Nov. 1882.

(*Mr. Bidder.*) The whole river is the domain of the Conservators in the same sense.

(*Mr. Lumley Smith.*) These dredgers are the servants of the Trinity House, and they are allowed to go where they like to get ballast for their own profit. If they get too near the banks in places where they will do harm they are warned off either by the Trinity House or by the Conservators; but they are not ordered to go to any particular place.

(*Mr. Beaumont Morice.*) And they go for the purpose of getting ballast, and not for the purpose of dredging.

3876. (*Mr. Bidder.*) It is the first time that I ever heard that the business of the Trinity House was to sell ballast; I thought that they had a deep interest in the navigation of the river. (*To the witness.*) After that, as I understand, recently you went to Long Reach?—Yes.

3877. In order to get a better quality of gravel?—Yes.

3878. And there you got what you wanted?—Yes, and we get it at the present time.

3879. It is quite different from the sewage mixed stuff that has been spoken of higher up?—Yes.

3880. Do you mean that it is sharp and clean?—Yes; there is clean red gravel there at the present time.

3881. If you go to Half-way Reach, or to Erith, then you get a nasty soft mud, and if you go into Long Reach you get a clean red gravel or sand, I suppose?—Yes, there is some sand with it.

Examined by the Commission.

3882. (*Mr. Abernethy.*) Can you find that gravel in all parts of Long Reach?—No, not in all parts. It is deep water in the centre of the reach; there is very good gravel on the south shore, and very good on the north shore. We are not allowed to work in the channel on account of the large ships that come up and down; the harbour-master orders us to one side or the other.

3883. Do you find red gravel all over that reach?—We are not allowed to go all over it.

3884. (*Chairman.*) But in all such parts as you have been over you have found nothing but clean gravel?—Yes, clean gravel.

3885. As high up as Purfleet?—Yes.

3886. Do you know the mud up there?—No; I have been down with the staff below Purfleet, and found nothing but soft sewage matter and mud.

3887. But that is in Long Reach?—At the bottom of Long Reach, on the north shore.

3888. You find mud there?—Yes, on the shore.

3889. (*Mr. Abernethy.*) You told Mr. Bidder that you found nothing there but shoal?—Not with the dredger. The shore in the river is not so clean as it used to be. I do not say with the dredger because we cannot go on the shore.

3890. (*Chairman.*) Have you found any of this offensive matter in Long Reach?—No, not at present.

3891. You tell us that you get up beautiful red sand and gravel by dredging; but I ask you whether below Purfleet you find any of this dirty stuff that you have been speaking about?—We have not done so yet with the dredger.

3892. I am not asking you about the dredger, but as an experienced man, and knowing that part of the river, will you tell me where you have found any of that dirty stuff?—Where there is an eddy-tide there seems a settlement of mud.

3893. Whereabouts?—On the north shore away down to what they call Sun Point.

3894. Below Purfleet?—Yes, right down to the point. I see it on the shore.

The witness withdrew.

Captain Walter Shepherd called in, and examined by Mr. Beaumont Morice.

*Capt. W. Shepherd.*

3895. I believe you are the captain of the steam tug "Wildfire," belonging to the East and West India Dock Company?—Yes.

3896. How long have you known the River Thames?—Over 40 years.

3897. Do you remember the outfalls being opened?—I recollect their being opened, but I could not tell you what year it was in.

3898. Could you tell us if there has been any alteration in the river since the outfalls were opened?—The river has been in a very bad state.

3899. What do you mean by being in a bad state?—It smells very badly. There is a lot of refuse swimming about. I should suppose it was refuse from a sewer.

3900. Is there a smell to it?—Yes, a very bad smell, an odious smell.

3901. What kind of smell is it?—I can hardly tell you; it is a regular stink.

3902. (*Chairman.*) A stink of what kind?—Of sewage.

3903. (*Mr. Beaumont Morice.*) Has there been any increase of that during the last few years?—It was worse two years ago than it is now. We had hot weather in the summer months, and that caused it to be much worse.

3904. This summer it has been cooler?—Yes, it was cooler this summer.

3905. Can you tell us, from your knowledge of the river, how far sewage would go down the river on an ebb tide?—I should not think it would go further than the Lower Hope, the lower part of the Hope.

3906. Can you tell us how far it would go back on the flood?—I should not think it would reach much farther than Crossness. You mean from the Hope up.

3907. It would go as far as the Lower Hope, and then it would meet the flood?—Yes.

3908. Is the flood tide as strong as, or stronger than, the ebb?—The ebb tide is the strongest.

3909. Which will run for the longest time?—The ebb tide runs the longest.

3910. Can you tell the Commission how far you think it will come back on the flood?—To Crossness, or further.

3911. Why do you say that the ebb tide is the strongest?—The longest, I understood you.

3912. Is that so or not?—The spring tides are the strongest on the flood.

3913. But, taking the tides ordinarily, which tide is the strongest, and which would run the longest?—The ebb tide runs down seven hours, and the flood tide runs up five hours.

(*Chairman.*) There is all the difference between the spring tides and the neap tides, I suspect.

(*Mr. Bidder.*) Of course the ebb tide has to take down the fresh water as well as the salt water that comes up.

3914. (*Mr. Beaumont Morice to the witness.*) Have you ever ascertained how far anything starting on the flood would come back up the river?—That would all depend upon the weather.

3915. (*Chairman.*) Have you yourself noticed how far a thing would go up?—No, I have never noticed that.

3916. (*Mr. Beaumont Morice.*) Have you ever suffered any ill effects from this sewage?—Not any, any more than that I have felt a little bit queer, when I have called at Crossness, from smelling the odour. I have felt a sickness.

3917. You know the state of the mud, do you not, on the banks up and down the river?—Yes.

3918. Can you tell the Commission what that is like?—It is black and greasy.

3919. Is there any smell to it?—Yes, a very bad smell.

3920. What kind of smell?—It smells like sewage.

3921. Has there been, to your knowledge and observation, any increase of that deposit of mud or sewage in recent years?—There is not so much water in Halfway Reach as there was before the sewerage.

3922. Is that the case, not only in Halfway Reach, but in other reaches?—In the other reaches; but I can speak more of Halfway Reach, because I tried there, and I know by that.

3923. Do you know the lower reaches around Erith Bight?—Yes.

3924. Can you tell me whether there has been any increase there?—I could not say, because I do not travel so far down as that.

3925. But you say that where you have seen it, the increase is of this sewage type?—Yes, because I have picked it up on my anchor when I have had occasion to let go my anchor.

3926. And, therefore, you have no doubt about its being sewage?—No; you have to handle it then.

3927. Have you ever noticed any lumps floating about in the sewage?—Yes, any amount of them, balls of sewage.

3928. Have you seen them often?—Yes, very often; but not lately.

3929. When was the last time you noticed them?—I think I saw one on Monday, but previously to that I had not seen any for a long time, say a twelvemonth or more.

3930. Have you ever noticed any dead fish in the river, and on the banks of the river?—Yes; eels.

3931. When did you last see that?—About a fortnight ago. They were not on the banks of the river, but floating in the river, dead.

3932. Have you often noticed that before?—Yes, at times of the year.

3933. At this time of the year generally?—I believe these eels come down with the land water, and they get smothered down there at Crossness, and then you see them floating dead after that.

3934. Have you ever been down with barges drifting down the river?—Yes.

3935. On an ebb tide?—I have generally worked the short distances. I have been more used to sailing and steam boats, and tugging.

Examined by Mr. Lumley Smith.

3936. You have not, as I understand, made any observations or experiments to see whether the tide is stronger on the ebb or on the flood.

*Mr. Bidder objected to the question.*

*The Chairman ruled that the question might be put.*

3937. (*Mr. Lumley Smith to the witness.*) When you speak about the ebb tide being longer or stronger in its operation than the flood, have you made any observations at all for the purpose of seeing whether that is so or not?—No.

Cross-examined by Mr. Michael.

3938. You are, I think, the captain of the "Wildfire"?—Yes.

3939. Are you engaged every day in towing down barges to a point in the river near Erith?—Yes.

3940. How many barges do you tow down?—Five.

3941. Once a day?—Once a day.

3942. Do any of your men live in a hulk on the river itself?—Yes.

3943. That is moored, I think, close to Crossness?—Yes.

3944. How many men live there?—There are three stationed there, but they are not all there at one time.

3945. They live there and sleep there, do they not?—Yes, in their turns.

3946. How many men do you employ altogether?—There are five lightermen, and those three men down there.

3947. Do the lightermen take their turns with the three other men?—No; we go away with the steamboat to Erith, and are only too glad to get out of it.

3948. How long do those three men who are in this hulk stay at a time?—Perhaps an ebb tide. Then they moor their craft on the next flood, and then the other men take their turn.

3949. Where is it that you have noticed the smell from the water that you speak of?—When I turn the vessel round at Crossness.

3950. And how far does it extend?—When we turn round we are only too glad to get out of it; we do not stop to see how far it extends; but at Erith we have found plenty of refuse from the sewers, and we can smell it there.

3951. At what time of the year is this?—It is at all times of the year. It has not been so bad these last six or eight months as it was previously.

3952. And that is the only place where you have the smell from the water?—No, we have it coming up the river; up as far as Blackwall I have smelt it.

3953. The water itself?—The water itself.

3954. At what time of the year?—I daresay it was 12 months ago when I first saw it there.

3955. But I am speaking of the smell that you say arises from the water?—You get so used to the smell, because you are smelling it all up the river so far as it goes.

3956. How far up?—As far as Blackwall; as far as I go.

3957. Then all the time, and at all periods of the year, you smell the water as you go through it?—Yes; and sometimes it is worse than at others.

3958. (*Chairman.*) But you can smell it at all times as far as Blackwall?—You can smell it at all times as far as Blackwall, and you can see refuse.

Re-examined by Mr. Beaumont Morice.

3959. I understood you to say that you make short trips?—Yes.

3960. And you have not been in the habit of going up and down the whole length of the tide?—No.

3961. Therefore you cannot speak with any certainty with regard to how far the tide will extend, one way or the other?—No, I cannot.

3962. I understand you to say that the smell is not confined to Crossness, but that you smell it all up and down the river?—Yes.

3963. And that even when you go out of it to Erith, you find it bad enough there?—Yes.

The witness withdrew.

Mr. Augustus Robert Edmunds called in, and examined by Mr. Beaumont Morice.

*Mr. A. R. Edmunds.*

3964. What are you?—I am a barge builder.

3965. And you live at Blackheath, I think?—Yes.

3966. How long have you known the River Thames?—All my life.

3967. (*Chairman.*) Shall we say 50 years?—Yes.

3968. (*Mr. Beaumont Morice.*) Do you remember the outfalls being opened?—Yes.

3969. Has there been any difference in the state of

*Mr. A. R. Edmunds.*

22 Nov. 1882.

the river from the time that the outfalls were opened?—Yes.

3970. In what way?—The upper reaches of the river, that is to say, from London Bridge to Limehouse, have become purer, and the lower reaches have become more foul year by year.

3971. What do you mean by saying that they have become more foul?—The water has been thicker, and the smell has increased.

3972. (*Chairman.*) In sweetness?—No. There was always a bad smell in the upper reaches before the cholera; and that same kind of smell is now in the lower reaches.

3973. (*Mr. Beaumont Morice.*) What was the smell like?—It is a closet smell, but weaker, and more sickening.

3974. Has that been increasing year by year?—In the lower reaches.

3975. Have you ever felt any ill effects from that?—In the summer time almost every morning; in fact every morning.

3976. In what way does it affect you?—I leave home quite well (my works are in the marshes down at Point Wharf, East Greenwich), and as soon as I get to the steamboat pier at Greenwich I feel unwell. Then I am on the river almost all day; my counting-house is almost on the water.

3977. In what way do you feel the effects of it?—In the summer I have my breakfast at Blackheath at 8 a.m., and sometimes I am not able to eat again until 5 or 6 in the evening; and that happens for weeks together.

3978. (*Chairman.*) Then it is loss of appetite that you suffer from?—Loss of appetite and faintness. Of course from want of food I am faint.

3979. Do you know the state of the mud on the banks of the river about Blackwall, or below there?—Just round the point in Bugsby's Reach I know it well; I pass it every day.

3980. That is the reach below Blackwall, is it not?—Yes, below Blackwall Reach; the next reach to Blackwall Reach is Bugsby's Reach. My works are at Blackwall point, East Greenwich.

3981. Do you go there?—Yes; there are my works (*pointing them out*). Every day I come there, and every day I cross Bugsby's Reach to go on the other side of the river.

3982. Can you tell us the state of the mud on the banks of the river up to the point you go to?—It is brown on the top and black as ink underneath.

3983. Is it mud?—Yes, it is thick mud and very stinking.

3984. Is there any particular smell to it?—A very bad smell indeed. As I row past it every day in the summer time it is exceedingly offensive.

3985. (*Chairman.*) What kind of smell?—Precisely the kind that I have described, a closet smell, but fainter. That is the nearest description of it I can give.

3986. (*Mr. Beaumont Morice.*) Have you noticed that at more than one part of the river?—Yes, at Cubitt Town my nephew has a place, and it is very black there.

3987. I believe you pass several of the steamboat piers during the day?—Yes, continually.

3988. Do you notice it there at all at the different piers?—There is the same description of mud at almost every pier, but it is better as you go higher.

3989. Have you ever had any persons in your employ who have suffered illness from this?—Yes, 30 years ago.

3990. Within the last few years have you had any sickness amongst your men?—No, I have not had any sickness amongst my men, not sickness unto death; none of them have died.

3991. (*Chairman.*) Have you had any sickness amongst your men during the last few years?—No.

3992. (*Mr. Beaumont Morice.*) You go down the river in a steamer very often, do you not?—Yes.

3993. Have you noticed the water of the river that is stirred up by the steamers?—Yes.

3994. What is that like?—It is of the same smell and the same colour as I have described.

3995. (*Chairman.*) Is this between Greenwich and Blackwall?—Right away up to Limehouse.

3996. (*Mr. Beaumont Morice.*) Have you ever gone further down the river than you have been telling us about?—Yes, continually.

3997. How far have you gone down the river?—To Gravesend.

3998. Have you ever noticed anything of this kind with regard to the mud or the smell that you have been mentioning lower down the river?—It is bad right away from Blackwall to Gravesend.

3999. (*Mr. Bidder.*) The smell, or the mud, or the water?—The smell, and the mud, and the water.

4000. (*Mr. Beaumont Morice.*) Are there any parts where you have specially noticed it?—Especially where the sewage outfalls are, at Crossness and Barking, and right away to Gravesend, and especially at Gravesend, as I have sat there.

4001. Could you tell, from your experience on the river, how far anything would be taken down on an ebb tide?—Yes.

4002. (*Mr. Bidder.*) Have you made observations?—Yes; when I was young I served my time as a lighterman, and I know exactly how far a barge will drift on the tide.

4003. (*Mr. Beaumont Morice.*) Speaking from your experience, how far would a barge drift on an ebb tide starting from a given point?—It would drift from Crossness to Gravesend on an ebb tide, but not further.

4004. You have actually noticed that?—Yes, I have rowed a barge down.

4005. (*Chairman.*) Then that is more than drifting?—Scarcely more, because you lay the barge athwart, and it drives.

4006. (*Mr. Beaumont Morice.*) If you got as far down as Gravesend on the ebb, and then started back on the flood, how far back would you be likely to drift?—The barge would drift almost as far back, I should think.

4007. (*Chairman.*) Have you tried?—Yes, I have brought a barge back from Gravesend in one tide. A barge would come back as far, and I conclude that the sewage would come back as far too.

4008. But you have tried a barge, and a barge has come back as far as from Gravesend to Crossness?—Yes.

4009. You have drifted down in a barge from Crossness to Gravesend on the ebb tide?—Yes.

4010. And then on the flood tide you have come back from Gravesend almost as far as Crossness?—Yes.

4011. (*Mr. Beaumont Morice.*) Have you ever noticed any lumps floating in the water?—My men have picked them up. I have not noticed them myself.

4012. Have you ever noticed anything on the top of the water, any grease, or anything of that kind?—Continually, slime.

4013. Has there been any increase of that lately, in the last few years?—There is an increase of it every year.

Cross-examined by Mr. Bidder.

4014. How often do you go down the river below Blackwall to Gravesend or Barking?—Formerly?

4015. Now, I mean?—Four or five times during the summer.

4016. For amusement, or on business?—For business and amusement.

4017. When you tell the Commissioners that the lower reaches are worse, you mean from Limehouse, how far?—Right away to Gravesend.

4018. About Limehouse you say it is better?—Above Limehouse I know it is better.

4019. This smell that you speak of, I understand, you notice everywhere every day?—In the summer time every day.

4020. And the mud; is that confined to the summer, or is it always so?—It is not always so; it is confined to the summer mostly.

4021. I do not know whether you can charge your memory with the appearance of the mud in the river 20 years ago; do you recollect what the mud used to be like?—I can remember it 30 years ago.

4022. Did you ever see mud at that time which was brown above and black beneath?—Yes, in the upper reaches at Limehouse, and near London Bridge at Fresh Wharf.

4023. And lower down too?—Lower down not so much.

4024. Still it was to be found?—Yes, but rather of a more yellow quality; not so black.

4025. But the yellow is above and the black is below?—Yes.

4026. You do not suggest that this brown at the top is a coating of something different from the rest of it?—I should think that it was made brown by the action of the atmosphere on it, but I am not chemist sufficient to tell you the reason for it. It might be a kind of oxygenizing.

Re-examined by Mr. Beaumont Morice.

4027. In fact, 30 years ago the upper reaches were worse, and the lower reaches were better, than they are now?—Yes.

4028. And now the matter is just changed?—Yes, that is so.

The witness withdrew.

Mr. George Saunders called in, and examined by Mr. Beaumont Morice.

4029. I believe you live at Erith, and you are foreman to Messrs. Beadel Brothers?—Yes.

4030. Have you lived near the Thames or about 21 years?—Yes, I have lived there 21 years.

4031. How have you been engaged during that time?—I have been engaged under Mr. Beadel in that time, and I have been foreman for him for about 16 years.

4032. But what have been your duties during the time?—Working on the wharf and about the wharf.

4033. Then you have been alongside the river mostly?—Yes.

4034. Do you remember the river before the outfalls were opened?—Yes.

4035. Can you tell us if there is any difference between then and now?—Yes, there is a great difference.

4036. In what way?—The water is much thicker, and there is dirty stuff in it now, and a great accumulation of sewage stuff in the berths where the ships come, and we have great difficulty in keeping them clean.

4037. Accumulation of what?—Accumulation of mud—sewage stuff.

4038. How can you tell that it is sewage stuff?—Because it smells so strong.

4039. What kind of smell is it?—A nasty sort of smell, something like what comes out of sewerage.

4040. Have you ever had any barges or vessels sunk in the river off there?—Yes, we have.

4041. How long ago?—We had one sunk about two years ago.

4042. When she was raised, in what state was she?—In a fearful state.

4043. (*Chairman.*) What do you mean by a "fearful state"; what was the condition of the barge when she was raised?—There was a kind of sewage mud in the barge when she was raised.

4044. Have any of your men been ill owing to this?—Yes, I have had several of them laid up these last two or three years.

4045. (*Mr. Beaumont Morice.*) Do those men work at discharging the ships?—Yes.

4046. Has that happened more of late years than it used?—Yes, more lately, because I have got a club on the wharf to which they pay 6*d.* a week, and I used to be able to keep that up, and now I cannot; so Mr. Beadel helps me a little to keep on with it.

4047. Has there been more illness amongst your men of late years than there used to be?—Yes, there has.

4048. Have you much mud up above Erith?—I do not know much about above Erith.

4049. Do you have more mud now in the berths where the ships are than there used to be?—Yes, a great deal more, because we only used to have one man in occasionally, and now I am obliged to have one regularly, and sometimes three, and sometimes more, to keep the berths clear.

4050. What sort of stuff is that mud?—It is a kind of sewage, black mud.

4051. How long was this vessel that was raised under water?—She was under water for about two days, I think.

4052. (*Professor Williamson.*) What do you suppose was the cause of the illness of your men?—I can hardly say.

4053. You have no reason to attribute it to any one thing?—No, to no one thing in particular.

Cross-examined by Mr. Bidder.

4054. These men actually work in the mud, clearing the channel, do they not?—I have got three doing that.

4055. Were any of those men laid up this year?—Yes; I have got some of them laid up at the present time.

4056. How many of them?—I have got three laid up now.

4057. Is a doctor attending them?—Yes.

4058. We will hope that he knows what is the matter with them?—I daresay he does.

4059. What is the name of the doctor?—Jesset is the doctor's name.

4060. Do you suggest that they are all laid up on account of the smell of the river?—I cannot say.

4061. I suppose you have had this sick club for many years?—Yes, I have had it for 14 years.

4062. And you have had men from time to time laid up, and upon it?—Not at all times; sometimes we are pretty free; but they have been worse lately.

4063. Lately you have had more occasion to have men working in the mud than you used, have you not?—Yes.

4064. And in the water too, I suppose, because they have to get wet working in this mud?—No, the tide leaves the berths altogether.

4065. They go in in long boots, do they not?—In long boots.

4066. You say that there is more mud than there used to be on your side of the river?—There is.

4067. You call it sewage stuff; may I assume, that like other witnesses, your reason for that is simply because it looks nasty and smells nasty?—Yes, that is it.

4068. You have not analysed it, I suppose?—I have not; but it smells very strong in the summer time.

4069. By-the-by, when you talk about the mud smelling strong, do you happen to have the Erith sewer discharging at your wharf on to the mud right under your nose?—No; there is a sewage place just below there; but I do not think it is from that, I could not say. There are some pipes laid down just below the wharf.

4070. Are they sewage pipes?—I believe so.

4071. Is the Erith sewage discharged through them?—Yes.

4072. On to the mud in front of your wharf?—No, not in front; a good bit below the wharf.

4073. How much below the wharf?—Well, I could not say. I have not measured it.

4074. (*Mr. Abernethy.*) Do you mean to say that

*Mr. G. Saunders.*

22 Nov. 1882.

all the sewage of Erith is discharged through those pipes?—No, not half of it, I believe.

4075. (*Mr. Bidder.*) A considerable portion of it is discharged through them, is it not?—Yes, I believe so; but I could not say how much.

4076. Is it about 100 feet from your wharf?—It is further than that; it is nearer 100 yards, I should think.

4077. We can have it measured afterwards. Of course that is washed up with the flood and down with the ebb, I suppose?—Yes, I suppose so. I have never been down to the place.

4078. Would you say that that Erith sewage does not smell?—I could not say. I have not been down to the end of the pipes.

4079. You have never been conscious of any smell from it?—No.

4080. Do you happen to know the other Erith sewer (because we had some doubt about it in the case of the previous witness) which discharges at that causeway?—I have never seen one there.

4081. (*Mr. Abernethy.*) What is the size of the pipe?—It is about a 6-inch pipe, I think.

4082. (*Mr. Bidder.*) Is it not a good deal more than 6 inches? It is suggested to me that it is 15 inches. Will you undertake to say that it is not more than 6 inches?—I could not say.

4083. I have a reason for asking, because I am told that it is larger?—I will not undertake to say.

(*Mr. Beaumont Morice.*) I propose to have the surveyor here next time; and I do not propose to ask this witness any question on the point because, of course, he knows nothing about it.

The witness withdrew.

Mr. Thomas Marshall called in, and examined by Mr. Beaumont Morice.

*Mr. T. Marshall.*

4084. What are you?—By trade a wheelwright.

4085. You live at Erith, do you not?—Yes.

4086. And I believe you are also the sexton of Erith?—I held that appointment.

4087. How long have you been at Erith?—17 years.

4088. (*Chairman.*) How long have you been sexton?—About 14 years.

4089. (*Mr. Beaumont Morice.*) I believe you had to do with a great many of the bodies from the "Princess Alice" disaster?—Somewhere about 30, I think; it might have been 32 or 33, I suppose.

4090. (*Mr. Bidder.*) You buried them, I suppose?—No.

4091. (*Mr. Beaumont Morice.*) When did you first have to do with them?—The first I had to do with drowned bodies, generally, was some 14 years ago.

4092. You had to do with some of the bodies of the "Princess Alice"?—Yes, with about 30, I think.

4093. When did you first have to do with them?—Some of them were brought ashore the very night of the accident.

4094. (*Chairman.*) You received some of the bodies on the night of the accident?—Yes.

4095. How many bodies did you receive?—I think on the night of the accident we received about 10.

4096. (*Mr. Beaumont Morice.*) Can you tell us what time of night it was?—They commenced coming very shortly after the accident; I think about two or three came in the very first boat that was brought ashore.

4097. But what time of the day was it?—At about 9 o'clock at night, I take it.

4098. In what condition were those 10 bodies?—In a very dirty condition.

4099. Will you explain what you mean by saying that they were very dirty?—The pockets of the men and the clothing of the women were one mass of mud, filth of some kind.

4100. What kind of mud or filth was it?—It looked like sewage; and I take it that it was sewage by the smell.

4101. When did you receive any more bodies from the "Princess Alice"?—We received them the next day and the following days for something like a week.

4102. In what condition were those that you got the next day?—They were in a very much worse state.

4103. What do you mean by "very much worse"?—The bodies smelt very much worse.

4104. (*Chairman.*) Not the clothing?—The clothing or the bodies, I could hardly distinguish which. There was a very much worse smell the longer they were in the water.

4105. (*Mr. Beaumont Morice.*) What kind of smell was it?—I could hardly describe it; it was a very horrible smell, almost as bad as a bad privy.

4106. Were they in a different condition from those that you had out of the water 14 years ago?—Yes.

4107. You stated that you had bodies out of the water 14 years ago; where did you receive them from?—From all parts of the Thames within the district of Erith; from just the other side of Crossness where it joins Plumstead, to Crayfordness.

4108. What do you mean when you say that they were in a better condition?—They were not so foul not so full of muck and mess as they are now.

4109. Have you received bodies taken from other waters except the Thames?—Yes, I have had three bodies out of the spring ditches, out of the marshes, and in different parts of the parish of Erith.

4110. In what condition were they?—There was nothing the matter with them; no more than you would see in an ordinary corpse.

4111. None of the sewage that you mention?—Oh dear no!

Cross-examined by Mr. Bidder.

4112. I suppose that if a body falls into clean water and it is got out again, you find the clothes, though wet, to be moderately clean?—Certainly.

4113. But if it falls into mud you find the clothes dirty and muddy?—Yes.

4114. And if the mud happens to be mud that smells badly, the body and the clothes smell badly?—Naturally.

The witness withdrew.

Adjourned to Tuesday next at half-past 12 o'clock.

# EIGHTH DAY.

## Tuesday, 28th November 1882.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary*.

28 Nov. 1882.

(*Mr. Beaumont Morice.*) Perhaps it might be convenient if I now mentioned to the Commission that I have considered the suggestion which they threw out at their last sitting with regard to the class of evidence that I have been tendering to them. I have carefully considered the bulk of the evidence which has been laid before me and which still remains to be tendered, and I think it is only right to inform the Commission that, although there is a number of persons in different ranks of life who would be prepared to give evidence with respect to this matter, yet my case is that there is a widespread feeling of a particular kind. The evidence which I have called, more of which is still in reserve, undoubtedly goes pretty much to the same point, viz., that the pollution of the river is a nuisance and has been caused by this sewage. But beyond this, and beyond the class of evidence, mainly of persons who have spent their lives upon the water, or on the banks of the river, and who are therefore, I submit, well able to speak, from the actual experience which they have had upon this matter, so far as any scientific analysis is concerned, I am not prepared to go. The Commission will bear in mind that it is a matter of great expense to the various parties concerned, in any case, but especially so to the memorialists whom I represent here. Therefore they, having been instrumental in obtaining the appointment of the Commission upon the representations to which I have referred, have thought it right to bring forward a mass of evidence for the purpose of placing it before you. But inasmuch as I have already called before you a number of witnesses who have given more or less the same kind of evidence, without desiring to close my case, or to be thought to close my case, relying upon the evidence of those whom I have already called, I would wish to put before the Commission that there are in reserve a large number of witnesses who have already been tendered to me, but who, I am bound to say, will to a great extent say the same thing as has already been given in evidence here on previous occasions. That being so, I have to-day directed to have brought here the surveyor whom the Commission intimated their wish to examine with regard to the drainage of Erith. I have also summoned Dr. Jessett, who is the medical officer of Erith, to speak with regard to some matters which the Commission wished to know about; and further, witnesses, more or less drawn from different parts of the river, who will be quite sufficient to occupy the rest of this sitting. But having mentioned that, I should be glad if the Commission would make some intimation to me with regard to the remaining evidence, which, on my own responsibility, I am hardly in a position to say that I am not prepared to call; because it is the case of the memorialists, who have been put to considerable expense in this matter, that the nature and character of this nuisance is widespread; and that is the matter which they chiefly wish to lay before the Commission.

(*Mr. Bidder.*) In fairness to my learned friend I ought to point out this: I can readily believe that, as we have already had a considerable number of witnesses who complain of things which they think, and no doubt sincerely think, are attributable to the outfalls, so probably there are a considerable number more who will come and do the same; but it must be distinctly understood that at the proper time, so far from admitting that the nuisance is attributable to the sewage outfalls, I shall be prepared with evidence of various descriptions, scientific and otherwise, to satisfy the Commission that my learned friend's clients are under a misapprehension as to the cause of that which they complain of.

*The Commission deliberated.*

(*Chairman.*) You have produced a large number of witnesses, Mr. Morice, and we have no doubt that you could produce a large number more, to prove the fact that where the sewage falls into the river, lower down, and perhaps even further up, a good deal of unpleasantness is felt by persons who are on the river or in the neighbourhood of the river. But assuming that to be the case, there still remains the important question, which has been barely touched upon by one or two of your witnesses, and that is how far it affects the health of the people there. Reference was made to a Dr. Jessett. If you could give us some evidence to show that the health of the people suffered from this flow of sewage into the river, it would, I think, be very material, and we should be glad to hear any evidence of that kind. I do not mean to say that a nuisance may not exist without being prejudicial to health; but we want to keep the two things distinct; first, whether there be a nuisance, and secondly whether that nuisance is prejudicial to health. And in considering that latter point you will not forget the hint that was thrown out just now by Mr. Bidder, that it is not enough to show that people are sick in that neighbourhood, but it must be shown that the sickness arises from the sewage, and not from other causes to which in the course of his cross-examination he has more than once referred.

(*Mr. Beaumont Morice.*) I have requested the medical man, Dr. Jessett, to be here in the course of the day, and he will speak with regard to that. I quite appreciate the distinction between the nuisance *per se* and the injury to health, and it has been principally with regard to the nuisance *per se* that I have endeavoured to produce evidence. But I thought it my duty to mention this, having regard to the fact that I have been supplied with a large number of witnesses who would testify to pretty much the same thing, and the Commission might naturally expect that I should give them some information as to the course that I proposed to pursue.

(*Chairman.*) The Commission will, in all probability, at a very early date, take other means of ascertaining whether it is a nuisance or not. We shall visit the place ourselves and examine it carefully, and then we shall be in a better position to test the value of the evidence laid before us.

(*Mr. Beaumont Morice.*) I thought if I formally tendered the remaining witnesses that I have, then, perhaps, the Commission would state whether they thought it desirable to hear any further evidence.

(*Chairman.*) I think we have had quite enough of that kind of evidence for the present, and perhaps you would now give us some evidence relating to the health question. I think you mentioned that you had the surveyor here.

(*Mr. Beaumont Morice.*) I believe he will be here directly. I have understood that he is coming up this morning.

Mr. RICHARD JOHN NAYLOR called in, and examined by Mr. BEAUMONT MORICE.

*Mr. R. J. Naylor.*

28 Nov. 1882.

4115. I believe you live at Woolwich?—Yes.

4116. And you are an ironmonger there, I think?—Yes.

4117. And you are one of the overseers of the poor?—Yes.

4118. How long have you lived at Woolwich?—Nearly 17 years.

4119. How long have you known the River Thames?—I have known the River Thames over 30 years.

4120. Do you remember the outfalls being made?—Yes; I think it was about the year 1865.

4121. Has there been any difference in the state of the river since the time when the outfalls were opened?—I should think that the river has been in a much worse condition since the outfalls were opened than it was before.

4122. In what way?—I notice that as soon as the tide begins to flow a thick muddy substance comes up with the tide, and the smell in hot weather is something intolerable, at times. Of course it depends upon the wind; sometimes it is not so bad as at other times.

4123. Have you had anything to do with dead bodies in the river?—Yes; I had a very great deal to do with dead bodies during that lamentable accident which occurred to the "Princess Alice."

(*Mr. Bidder.*) We have had the coroner and the deputy coroner and his officer up.

4124. (*Mr. Beaumont Morice to the witness.*) In what state did you find those bodies?—They were in a filthy black state, as if they had been black-leaded; they were a sort of blue black.

4125. (*Mr. Bidder.*) Do you mean that they were shiny?—Yes, they looked shiny, as if they had been black-leaded. I think we might attribute that to sewage matter, for this reason: many years ago, before the system of pans and trapping closets was introduced, I have noticed that the insides of water-closet doors were of a bluish-black colour, the same as I have described that these bodies were, and I could only attribute that to the smell that arose from the closet.

4126. (*Mr. Beaumont Morice.*) Was that so on the bodies generally?—On the whole of them. On one day I had occasion to see nearly 500 bodies, and they were all alike.

4127. (*Chairman.*) Nearly all black?—Nearly all black.

4127*a*. (*Mr. Beaumont Morice.*) Have you ever had anything to do with bodies out of other waters?—I have occasionally seen drowned bodies that have been recovered from other rivers, but very seldom.

4128. Has there been any difference between those and the bodies that have been recovered from the Thames?—I have noticed that they have been of a natural colour, and that, as a rule, they were covered with weeds; but in this case the clothing was filthy, and covered with a slimy matter.

4129. Do you know anything about the tides in the river?—No, I do not.

4130. Do you know anything about any sewage coming in near Woolwich, besides the outfall?—Yes; I know that the whole of the sewage from North Woolwich is discharged into the River Thames.

4131. (*Chairman.*) Do you mean at the Crossnes outfall?—No, I am speaking of Woolwich proper.

4132. (*Mr. Bidder.*) Nothing to do with th metropolitan outfall?—No; this is a metropolita outfall on a smaller scale.

4133. (*Mr. Beaumont Morice.*) What do you know about it?—I think about 10 years back a large reser voir was constructed, 250 feet in length and about or 10 feet in diameter, for the purpose of receiving th sewage from that portion of Woolwich which i situated on the north shore, that being discharge into the River Thames by the opening of a penstock which is opened, or should be opened, at every tide but, as I understand, it is not opened at every tide except in wet weather. This particular outfall tha I am alluding to is situated in the parish of Woolwich

4134. Is it marked on the map on the wall?—Yes I think I could point it out to you there. This por tion is in the county of Essex, and in the parish o East Ham, and this northern portion of the parish o Woolwich is in the county of Kent (*describing on th map to the Commission*). This portion might be 25 yards from the hotel in North Woolwich Gardens t the Barge House at North Woolwich. The norther outfall actually discharges its sewage in the metro politan area, which I believe the Act of Parliamen distinctly states that it shall not do. I might say tha they are breaking the law. Then the sewer that am speaking of is somewhere about here (*pointing t the map*); it is just a very few yards above the Nort Woolwich landing pier. I can show it you better o this hand map that I have here (*producing a map an laying it before the Commission*). That black spo denotes Henley's Telegraph Works, and you will se there a roadway called Henley Road. Underneat that road this reservoir is constructed, and the pen stock is opened at low water. That reservoir wa constructed at the expense of the Metropolitan Boar of Works.

4135. (*Chairman.*) Do I rightly understand you t say that that large reservoir is one of the works o the Metropolitan Board?—Yes; and I think the cos was 1,500*l*.

4136. (*Mr. Beaumont Morice.*) Do you notic much drainage coming from there?—Every time it i opened; in fact, it was made larger because it wa not large enough to contain the sewage of the neigh bourhood. At the time I am speaking of there wa a small reservoir there.

4137. (*Chairman.*) Mr. Morice's question is, D you notice sewage coming out of it?—Yes.

4138. (*Mr. Beaumont Morice.*) How often is i opened?—Every 12 hours; every tide, as the tid suits; and the man who opens it is in the employ o the Woolwich Local Board of Health. You must als understand that this portion which I point out here which is called North Woolwich, in the county o Essex, and in the parish of East Ham, also drains int the Woolwich sewer because they have no other mean of drainage.

4139. Therefore, I take it that a considerabl amount of drainage comes out of that sewer?—Cer tainly; I think there are about 250 houses in th parish of Woolwich at that particular spot, and should think there are nearly double that number, o about 500, in the parish of East Ham.

Cross-examined by Mr. BIDDER.

4140. Do you represent this sewage work at North Woolwich as being offensive?—Yes, certainly.

4141. And causing considerable smell?—Yes; I do not say it is all caused from that one particular spot where the small reservoir is, but from the larger one, the northern outfall.

4142. You represent that one as causing a bad smell in the neighbourhood?—Yes.

4143. And a sewage deposit on the mud?—That is so.

4144. That you say from your own knowledge?—From my own knowledge.

4145. And to a considerable extent?—To a con siderable extent. I have occasion to cross the wate very frequently on business matters.

4146. By the Woolwich ferry?—Yes.

4147. That is where you principally notice th smell in the river?—Yes, because sometimes we hav occasion to wait upon the pier for a quarter of a hour or 20 minutes.

4148. I do not know how you came in contact wit those 500 bodies; were you a coroner's officer?—

was overseer. I was called upon as one of the overseers, under this Act of Parliament, to bury the unclaimed dead.

4149. We need not discuss the Act of Parliament. I understand you to say that they looked as if they had been polished with blacklead?—Yes.

*Mr. R. J. Naylor.*

28 Nov. 1882.

Examined by the COMMISSION.

4150. (*Dr. Stevenson.*) How long had those bodies been in the water when you saw them?—Some of them only a short time. The accident occurred on the Tuesday evening, and it was on the Saturday evening and Sunday that the larger number of bodies were brought on shore, but those that were brought on shore earlier were black.

4151. But when did you see them black?—On the Saturday. I was not called upon to see them until the following Saturday.

4152. (*Chairman.*) The accident occurred on Tuesday, and you saw them on the following Saturday?—Yes.

4153. (*Dr. Stevenson.*) Had most of them been taken out of the water on that day?—Most of them had been taken out of the water on Saturday and Sunday; but there were some taken out the same evening. There were some remaining there for upwards of a week, which were not identified.

4154. (*Chairman.*) The accident occurred on a Tuesday; when did you first see any bodies?—About 11 o'clock on the Saturday morning after the accident. That is the first time I saw any bodies.

The witness withdrew.

Mr. WILLIAM EGERTON re-called. Further examined by Mr. BEAUMONT MORICE.

4155. I think you are the surveyor to the Erith Local Board?—I am.

4156. And you have already given evidence here, I believe?—I have. I should like to make a correction with regard to one statement that I made. I made a mistake about the position of Jenningtree Point; I was not aware of the position of it at the time; I thought it was higher up than it really is.

4157. What you are referring to is what you said in answer to question 934, when you were asked about the factories?—Yes.

4158. Will you give the Commission some information with regard to the drainage of Erith. First of all, can you tell us how many houses there are in the parish of Erith?—1883 rateable houses.

4159. How is that number made up?—I do not remember the figures exactly; but if you follow the figures down you will see that they come to 1883.

4160. Of those 1883, how many are drained into the Thames?—507.

4161. That leaves 1376; what is their system of drainage?—They drain into cesspits.

(*Chairman.*) We need not trouble ourselves about them; they do not interfere with the Thames.

4162. (*Mr. Beaumont Morice to the witness.*) For the purpose of draining those 507 houses what sewers are there leading to the Thames?—The public sewer, the outlet to a sewer that runs off the South-eastern wharf; that is a 15-inch iron pipe at the outlet.

4163. Is that what you call the public sewer?—That is the public sewer. There is another public sewer from the Bexley Road across High Street into the Thames; that is a 12-inch pipe.

4164. (*Mr. Bidder.*) Where does that go into the Thames?—Opposite a beershop in the occupation of a man of the name of Wiggins.

4165. Is it near the causeway?—No, it is farther east than the causeway.

4166. (*Mr. Beaumont Morice.*) Is there any other?—There is another that comes down Cross Street, which I think is about a 9-inch pipe, but I am not quite sure. I could not see the outlet; that is only a branch.

4167. (*Chairman.*) Where does that discharge?—That discharges close by the steam flour mills.

4168. (*Mr. Beaumont Morice.*) That is a little above the causeway?—It is.

4169. Is that an iron pipe?—No, it is an earthenware pipe.

4170. Are there any others besides those three?—Not public sewers. There is another 6-inch outlet from some works occupied by Messrs. Shuttleworth and Chapman; it comes out opposite their works.

4171. What are they?—Engineers and shipbuilders. Their works are on the Wheatley Terrace Road.

4172. Is that below the first public sewer that you have mentioned?—Yes.

*Mr. W. Egerton.*

4173. Are there any other sewers besides the three public sewers and the one at Shuttleworth's?—Not that I am aware of.

4174. Are there any what you may call little drainings from the houses?—Ther e may be.

4175. (*Chairman.*) But do you know whether there are?—No, I do not.

4176. (*Mr. Beaumont Morice.*) As the surveyor to the local Board, are these all the sewers that you know of?—All that I am aware of that empty into the Thames. Of course they all empty into the Thames.

4177. (*Mr. Bidder.*) Have you a plan upon which they are marked?—I have not.

4178. (*Mr. Beaumont Morice.*) Do you know anything about the gulleys which lead into those sewers?—Yes; from all the public roads where the surface water is drained into the sewer there are catch traps or gulleys.

4179. Are those attended to from time to time, to your knowledge?—Yes they are.

4180. How often are they attended to?—They vary from a week to a month. If there are heavy rains they are attended to every week; and in dry weather, when there is very little water going in, perhaps they are not attended to for three weeks or a month.

4181 But you know as a matter of fact coming within your own knowledge that they are attended to from time to time?—I do.

4182 Have you any information as to how many persons there are in those 507 houses which are drained into the Thames?—We generally reckon about five to a house, and that would make it about 2500.

4183. You know where the mud lies about Erith?—Yes.

4184. Are there any sewers where the mud lies thickest?—No; where the mud lies thickest is nearly opposite the two ballast wharves. I might remark that where the largest sewer is there is less mud and filth; that is the 15-inch sewer.

4185. That is opposite the South-eastern wharf?—Yes.

4186. That will be below Erith Pier?—Yes. I noticed it this morning more particularly; I have been round there this morning.

4187. Can you tell us how far that main sewage pipe runs into the river at low water?—I could scarcely tell you; I should think 80 yards, but I have never measured it, and I could only guess at it.

4188. (*Mr. Abernethy.*) Does it run to low-water mark?—No.

4189. (*Mr. Beaumont Morice.*) Can you tell us how far it is out of the water at low water?—No, I could not.

Cross-examined by Mr. BIDDER.

*Mr. W. Egerton.*

28 Nov 1882.

4190. First, with regard to these sewers, the rest of the houses, you say, drain into cesspools?—Yes.

4191. Have those cesspools no overflow?—No, they have not.

4192. None whatever in any case?—Not that I am aware of.

4193. They are absolutely self-contained?—So far as I know.

4194. You have mentioned several outlets into the river; am I right in identifying the 15-inch pipe, that you mentioned first, as being situated opposite the Erith Gardens, a little below the pier?—Yes.

4195. I am told that what are called the Erith Gardens are not gardens now?—No, they are not; it is the South-eastern wharf.

4196. And close to the wharf of that gentleman who gave evidence the other day, and said that his men complained of the smell when they were clearing away the mud?———

4197. (*Chairman.*) Is it near the house of Mr. Beadel?—No.

4198. Near whose place of business is it?—It is near Mr. Beadel's place of business; it is known as the South-eastern wharf. Mr. Frank Beadel lives not far from the outfall. Messrs. Easton, Anderson, and Company's and Messrs. Shuttleworth and Chapman's are the two places of business.

4199. (*Mr. Bidder.*) I am right in identifying this pipe as being near that wharf?—Yes.

4200. About how many feet is it from it?—As I have already said, I think it might be about 80 yards.

4201. Is the end of the pipe in a fractured condition, so that the sewage does not go to the end of it?—I do not know.

4202. Is there also an outlet which I do not identify with any of those you have mentioned, about 15 inches in diameter, close to the Erith Causeway?—No; there is one that I said was about 12 inches near the Erith Causeway.

4203. Perhaps we are talking of the same thing; is it immediately above Erith Causeway?—No, below it.

4204. How far from the causeway?—Perhaps 50 or 60 yards; I will not say exactly.

4205. Are you not aware that there is an outlet from which either sewage, or water, or some liquid, is discharged into the river immediately above the Erith Causeway?—That is the one that I spoke about as being a 9-inch earthenware pipe.

4206. How far is that from the causeway?—Perhaps it might be 30 yards, but I have not measured it.

4207. According to your memory, there is one 60 yards below and another 30 yards above?—Yes.

4208. Many of those sewers, whatever the amount of the population may be, are very offensive in the matter that they discharge, are they not, and cause a considerable nuisance upon the banks of the river?—I do not know, I am sure. I should think there is more caused by the mud that accumulates from the outfall than there is by them.

4209. Did your board some four or five years ago invite an engineer of eminence to report upon the sewers of Erith?—I do not know that they did.

4210. Did you ever hear of Mr. Edward Easton?—I know Mr. Edward Easton, and I know that he prepared a scheme for draining Erith.

4211. Did he report upon the state of the drainage?—Yes, he did.

(*Mr. Bidder.*) I should like to ask my learned friend, Mr. Morice, whether he produces that report?

(*Chairman.*) I have no doubt that you will produce it if he does not; and, therefore, it seems to me that you will probably supply us, by some evidence of your own, with very far more authentic evidence of what you are trying to prove through this witness.

(*Mr. Bidder.*) So I shall at the proper time; but now the surveyor of Erith is here, and it is my bounden duty to put to him, and to give him an opportunity of contradicting, if he thinks proper, that which I am going to rely upon.

(*Mr. Beaumont Morice.*) I have no doubt that I shall be able to supply the report which my learned friend alludes to.

4212. (*Mr. Bidder to the witness.*) I want to know whether these are facts within your knowledge. To begin with, there is a sewer with a 15-inch pipe, which I have no doubt is the one you have already mentioned; do you know how many houses that drains?—No, I do not remember.

4213. Now, with regard to some other matters which I did not ask you about before, you have frequently had occasion to be consulted as to steps being taken with regard to the nuisance, smell and otherwise, arising from the factories at Erith about which complaints have been made?—Yes.

4214. Did you have a petition to the local authority in September 1880, two years ago, by a number of the ratepayers of Belvidere in respect of the serious nuisance arising from the factories on the river banks?—I could not say; it might have been handed to the local board, and I might not know about it. I do not remember it.

4215. I find from a paper of that date that this purports to have happened; that a memorial signed by 69 ratepayers——

(*Mr. Balfour Browne.*) That is not evidence.

(*Mr. Beaumont Morice.*) I do not want to interrupt my learned friend unnecessarily, but I really must take exception to this.

(*Chairman.*) The question is whether a certain memorial, of which you are seeking to give the contents, was presented to the Erith Board. If that memorial is to be in evidence it should be put in. If it is not, then it is a question whether the witness can charge his memory with the contents of that memorial.

(*Mr. Bidder.*) The people of Erith are here as memorialists complaining of smells and other nuisances in that neighbourhood, and attributing them to the outfalls of the Metropolitan Board. At the proper time I shall endeavour to show by evidence of my own that they are not attributable to the outfalls of the Metropolitan Board; I also venture to say that to a great extent they are attributable to other causes. Part of the evidence bearing upon that, it is not within my power to produce, because, for instance, the Acts of the local board are within their own knowledge, and more accessible to them than to the Metropolitan Board; and the best opportunity I can have is, when I get officials of the local board into the box, to cross-examine them as to whether complaints were not made or proceedings taken with reference to these other nuisances.

(*Chairman.*) You want to elicit a fresh fact, viz., that there has been a complaint in writing. If that complaint has been made in writing, the only way for you to bring it out in evidence is to produce that writing.

(*Mr. Bidder.*) It is not for me to produce that writing; I have not got it.

(*Chairman.*) I do not think that the question can be admitted.

4216. (*Mr. Bidder to the witness.*) Is it not within your knowledge that, in consequence of representations made to the local board, officials of the board were put in motion to take steps with reference to nuisances caused by the factories, in the autumn of 1880?—I do not know when the time was; but I believe it was so.

4217. Who is Mr. Ogston?—He is a professor of chemistry, I think; an expert.

4218. Was he employed by the local board?

(*Mr. Beaumont Morice.*) I think, if my learned friend will refer to the previous examination of this witness, he will see that we have had this before. At question 1027 he was asked about all these factories.

(*Mr. Bidder.*) I am not asking about the fish manure. Would you mind, sir, intimating to the other side that, in the opinion of the Commission, the original memorial should be produced? I cannot produce it.

(*Chairman.*) You can give them notice to produce it.

(*Mr. Beaumont Morice.*) I shall be very happy to produce anything that the local board possess upon the subject.

4219. (*Mr. Bidder.*) Then I pass on from that. (*To the witness.*) In January 1881, did you, as surveyor, report to the board upon a ditch at the back of Messrs. Price's works as being a nuisance?—I do not remember the date, but I have reported upon that.

4220. Was that a serious nuisance, in consequence of the offensive matter in it?—I should consider it a serious nuisance.

4221. Producing offensive smells, which were annoying to the residents in Erith?—Yes.

4222. (*Chairman.*) Was it an open ditch?—Yes.

4223. (*Mr. Abernethy.*) What was the size of that ditch?—I should think it was about 6 feet wide. The water in the lower part was not more than a yard wide at times; but in times of heavy rains it was much fuller.

4224. (*Colonel Ewart.*) Is this ditch in direct communication with the River Thames?—Yes, it has an outlet into the Thames.

4225. (*Mr. Bidder.*) Have the complaints on the part of the inhabitants as to the factories continued down, I may say, to within a few days of the present time?—Not that I am aware of.

4226. Was not a letter of complaint received by your board, and read at a meeting on the 17th of last October, with reference to the smell from the oil mills?—It may have been, but as I am never in the board room during the time of meeting, I cannot say.

4227. (*Chairman.*) Did you hear such a letter read at the board?—No, I did not.

4228. (*Mr. Bidder.*) You are directed to report upon these cases afterwards, are you not?—I have not been directed to report upon that case so lately as the 17th October.

4229. When were you last asked to report upon the oil works?—I do not remember.

4230. In this present year?—It may have been; I cannot say.

4231. (*Chairman.*) Are you speaking of Price's oil works?—Yes.

4232. (*Mr. Bidder.*) Have you any book, or account of your official work?—I have no diary.

4233. Have you any book in which you record them when you make inspections as surveyor?—No, I do not know that I have; I may have it in some of my pocket books.

4234. Am I wrong in saying that you have frequently had, as part of your duty, within the last two years to visit and report upon various factories which have been complained of as nuisances?—Yes, I think I have within the last two years.

4235. Frequently?—I do not say frequently.

4236. (*Mr. Abernethy.*) Do any of these factories discharge refuse into the Thames?—No, except the ditch at Price's factory that I have been speaking of before.

4237. (*Mr. Bidder.*) Is there a dung wharf fronting the river at Erith?—Yes.

4238. At which manure is loaded or discharged?—At which manure is discharged, not loaded.

4239. Have there been many complaints as to the nuisance caused by that dung wharf?—Not this year that I remember. I have had no complaints this year, but I have had complaints previously respecting the smell from the dung wharf.

4240. But you do not recollect having had any in the year 1882?—No.

4241. Have your board gone so far as to prosecute people for landing particularly offensive manure there?—I think so in one instance, but that I am not sure of; it was, I think, for letting manure remain a longer time than it should remain.

4242. But the cause of the prosecution was, of course, the nuisance created to the inhabitants?—It was for letting the dung remain too long.

4243. (*Chairman.*) You were not prosecuting, were you?—No, the board prosecuted.

4244. (*Dr. Stevenson.*) I suppose you would take out the summons?—No, I leave that to the solicitor. I think it was the clerk who filled it up, and I got it signed by the magistrates.

4245. (*Mr. Bidder.*) Did you give evidence?—Yes.

4246. Did you also make a formal report on various factories, very late in last year, in the November of last year?—I do not remember without referring back to the dates.

4247. Have you copies of your written reports?—I think I have.

4248. Can you produce them now?—I cannot.

4249. Do you remember, in the November of 1881, reporting on Messrs. Callendar's works, Messrs. Price's works, Messrs. Berger and Spence's works, and Messrs. Collins' works?—I think it is very likely that I did, but I do not remember the time.

4250. Did you report, as you told one of the Commissioners just now, to the effect that there was no drainage from those works?—

(*Chairman.*) Was the report in writing.

(*Mr. Bidder.*) If I cannot get the report, I must get the best I can.

(*Chairman.*) You cannot put in secondary evidence in this sort of way.

(*Mr. Bidder.*) But those who have the report do not produce it.

(*Chairman.*) You do not call upon them to produce it.

(*Mr. Bidder.*) Then I invite them now to produce it at the next sitting of the Commission.

(*Mr. Beaumont Morice.*) I am not aware at the moment that there is such a report; but I will endeavour to ascertain whether there is, and if there is I will undertake to produce it. But I would draw the attention of the Commission to what has already taken place here as to this matter. At question 1067 this witness was asked about having seen these factories, and whether they had been better or worse. Then he was asked whether any action was taken by the board, and his answer was "No; only notices were given, and "some alterations were made in the machinery and "in the condensers and the furnaces. (*Q.*) Was that "in consequence of a report made to the board?" (*A.*) It was"; so that my learned friend has really what he wants.

(*Mr. Bidder.*) My learned friend suggests that because he, in re-examination, asked a certain question and got a certain answer which pleased him, I am not entitled to cross-examine the witness.

(*Chairman.*) If these matters were really material, I should be more inclined to waive the question about the strict admissibility of the evidence, but I do not see what the point of it is at present. That you will be able, Mr. Bidder, to give us evidence that there are a number of offensive factories on the banks of the river I have not the slightest doubt, because it is a matter of notoriety.

(*Mr. Bidder.*) I am going to suggest to the Commission, when it comes to my turn, that the offence and nuisance of which the people of Erith complain is attributable, and is attributed by themselves, to a distinct cause; and, therefore, when I have the surveyor of Erith in the box giving evidence, it is my right, and not only my right but my duty, to put it to him.

(*Chairman.*) If you want his reports to his board, the proper course is to give the board notice to produce those reports, and no doubt Mr. Morice will at once produce any documents that you may require and that he possesses.

(*Mr. Beaumont Morice.*) Certainly.

4251. (*Mr. Bidder.*) I indicate a report which was presented at a board meeting held on the 8th November 1881. I will give my learned friend a list if there are any others that I want. (*To the witness.*) Is it a fact (because you said just now that there was no offensive drainage from these works) that from Messrs.

*Mr. W. Egerton.*

28 Nov. 1882.

Collins' works you have found both offensive stagnant water and offensive drainage?—That was from the hides and material lying on the river wall, which drained into the Thames.

4252. (*Chairman.*) You found offensive matter?—Flowing from the refuse that lay on the river wall, on the surface. There is no drain there.

4253. (*Mr. Bidder.*) But it drained into the Thames?—It drained into the Thames.

4254. (*Mr. Abernethy.*) Did that arise from rain falling on it?—Yes, that is all.

4255. (*Dr. de Chaumont.*) Are you inspector of nuisances for the local board as well as surveyor?—Yes.

4256. (*Mr. Bidder.*) Is it within your knowledge that about the close of last year a communication was made to your local board from the Local Government Board with reference to the complaints of persons of the offensiveness of those factories?—I am not aware of it.

(*Mr. Bidder.*) I ask my learned friend to produce a communication from the Local Government Board to the Erith Local Board.

(*Mr. Beaumont Morice.*) If my learned friend will give my clients notice, I will endeavour to do everything that is possible in the matter.

4257. (*Mr. Bidder to the witness.*) Do you remember that a committee of your board was appointed at the end of last year to investigate the question of the nuisances produced by the factories?—No.

4258. (*Chairman.*) Do you attend the meetings of the board?—No; I am not admitted to the board room. I get my instructions after the board meeting is closed.

4259. (*Mr. Bidder.*) At the end of last year did you assist a committee of the board in investigating the question of the factory nuisances?—I did some time last year, but I do not remember the time.

4260. Who were the members of that committee?—I do not remember who the gentlemen were.

(*Mr. Bidder.*) I will ask my learned friend to produce the report of that committee, if it exists, upon the question of the nuisance.

(*Mr. Beaumont Morice.*) We have the result of that in evidence already.

(*Chairman.*) Mr. Bidder's clients will of course give Mr. Morice's clients notice of the documents that they require, and they will be produced, I have no doubt, and we shall have authentic evidence on all these matters.

4261. (*Mr. Bidder to the witness.*) Have you been engaged also in this present year in reporting upon the nuisances of the factories?—No, I have not, since the new Act came into operation.

4262. When did the new Act come into operation?—On the 1st of January, I think it was.

4263. Besides the factories, have you recently had complaints of local nuisances, from cesspools and other offensive matters, compelling the people to keep their windows shut?—No.

4264. Did you not report, in May of this present year, upon a nuisance of that nature affecting houses in Picardy Street, Belvidere?—Not so bad as to have to close the windows. I may have reported, but I cannot say exactly.

4265. (*Chairman.*) Was it to you that the complaint was made?—I do not remember whether it was or was not.

4266. (*Mr. Bidder.*) You say that you had to report upon it?—If the notice was sent to me I should give them notice at once to abate the nuisance, and I should see that it was abated.

4267. But did you not make a report to the board?—I cannot remember.

4268. Do you know a gentleman of the name of Clare, who lives in Picardy Street, Belvidere?—I do not remember the name. I do not know the occupiers of the whole of the houses in Picardy Street.

4269. Have you had frequent occasion lately to serve notices to abate local nuisances?—I have served some notices.

4270. Are there certain manure works at Belvidere?—There are Collins and Company's works, and Proctor and Bevington's works, as I said before; but, as I have already said, I have not visited them this year.

4271. Were there complaints of these manure works in the summer of this present year?—I do not know.

4272. Was Mr. Ogston called in to report upon them, to your knowledge?—No, I do not think he was.

(*Mr. Bidder.*) I think perhaps it will save time if I ask my clients if there are any further reports that they desire to have produced, and then a list of them shall be made and furnished to my learned friend, Mr. Morice.

Re-examined by Mr. Beaumont Morice.

4273. You had complaints with regard to Picardy Street and other streets in the ordinary course of your business?—Yes; and I have copies of all my reports and notices, and they can be produced at any time.

4274. You have been asked about a ditch; can you tell us whether any action was taken with regard to that ditch?—Notice was given to Messrs. Price and Company in the ordinary course to abate the nuisance.

4275. Do you know whether there has ever been any alteration in the ditch?—Yes; they have had it all cleared out since.

4276. When was that?—Last year.

4277. With regard to these reports and inspections that you have made, what did they refer to?—Very great alterations in the process of the manufacture, and a very great abatement in the nuisance.

4278. Did you, as local board surveyor and inspector of nuisances, inspect those factories?—I did very frequently at one time.

4279. And until the coming into operation of the Alkali Act did you continue to do so?—Yes.

4280. And since you have inspected those factories has the smell from them been better or worse?—Very much better indeed.

4281. Do you know what became of that prosecution about the dung wharf?—No, I do not.

4282. The wharf is merely used for the purpose of landing; is that so?—That is all.

Examined by the Commission.

4283. (*Colonel Ewart.*) Are those 507 houses which you spoke of, which are drained into the Thames, modern houses or old houses?—A great number of them are cottages. Very few are old houses; they are mostly modern houses.

4284. Have they been built, do you suppose, during the last 17 years?—Yes; some of them; some of them were built previously to that time; some have been built 20 years.

4285. They are mostly cottages, you say?—Mostly cottages.

4286. Is there any distinction between those that have cesspits and those that are drained into the Thames as regards their age; are the cesspit houses the old houses or the modern houses, generally speaking?—I should think there are rather more new cottages that are drained into the Thames than old houses.

4287. Has there been any great increase in the population of Erith in the last 17 years?—Yes, there has been a great increase in the population.

4288. Do you know the number?—No, I do not, but I should think about a third more.

4289. In the case of those houses that drain into cesspits, what becomes of the slops, as they are technically called. The solid matter goes into the cesspits, I suppose?—And the slops the same. It all goes into the cesspits.

4290. But you said that they had no overflows?—They have no overflows from the cesspits.

4291. Are those porous cesspits?—Some of them

are, to a certain extent, where they have got into the gravel. In some places it is like putting the sewage into a pan, and they are emptied and taken away—on to the land mostly—by the farmers in the night.

4292. Are they frequently emptied?—It depends very much upon circumstances. I have had one cesspit emptied twice this year, and it was eight years since it was emptied before.

4293. Then the slops do not go into these drains which you have spoken of, which discharge into the sewer?—The slops and all go into the sewer where they are drained into the sewer.

4294. That is in the case of the 507 houses; but not from the other houses?—No; not from one of them that I am aware of.

4295. Have you any gasworks?—Yes.

*Mr. W. Egerton.*

28 Nov. 1882.

4296. What becomes of the refuse from those?—The ammoniacal liquor is put into barges and sent to London for some purpose; I do not know what.

4297. Nothing goes from these works into any drain?—Nothing.

4298. (*Dr. Stevenson.*) When you visit these factories, do you make your reports to the board in writing?—Yes.

4299. And you take notes when you visit them?—Yes, I take notes, and there are copies of all my reports.

4300. Although you do not keep a diary, you have notes of all your visits to those places?—Yes.

The witness withdrew.

Mr. JOHN WILLIAM SHOWELL called in, and examined by Mr. BEAUMONT MORICE.

4301. I believe you live at Greenwich?—Yes.

4302. And you are the deputy harbour-master?—I hold the warrant.

4303. And you are the inspector of nuisances and explosives, and things of that kind?—Yes.

4304. What part of the river is your particular district?—The lower part.

4305. Can you tell us the limits?—From Greenwich to Greenhithe and Long Reach.

4306. How long have you known the river?—From my boyhood; all my lifetime.

4307. You remember the outfalls being opened at Crossness and Barking?—Yes.

4308. Has there been any difference in the state of the river before and since that time?—Yes, a great deal of difference.

4309. In what way?—By reason of the pollution of the river and the bad water.

4310. In what way specially?—From the sewage.

4311. Do you see any difference in the water?—It is a different colour.

4312. Is it thicker?—A great deal thicker.

4313. Is there anything else that you notice?—There is a great deal of filth and sewage with it.

4314. Has it any smell?—There are great smells from it.

4315. You know the mud up and down the banks of the river?—Yes.

4316. Has there been any alteration in that lately?—None.

4317. Has there been any alteration in it as compared with the time before the outfalls were opened?—The mud is a different colour.

4318. Is it like ordinary mud?—No; it is more like a black substance, filth, and such like.

4319. Is that the case in one part more than in another?—No, along the shores.

4320. I suppose you know about the tides in the river pretty well?—Yes.

4321. Can you tell us how far anything put into the river at Crossness would get down on a neap tide?—I should think somewhere about the upper part of Gravesend Reach.

4322. Can you tell us how far it would come back on the flood?—To the best of my judgment I should think about Tripcock Point.

4323. That is above Crossness?—Yes.

4324. Do you consider that the flood is stronger than the ebb, or not?—You would drive further on the flood than you would on the ebb.

4325. So that it would drive further back than it would go down?—Yes.

4326. Can you tell the Commission from what you have noticed whether the sewage matter passes down the river or settles down in portions of it?—It settles down in portions of it.

4327. Whereabouts do you say it specially settles?—From which sewer; at Barking or Beckton?

4328. Say Crossness?—Then it settles about the lower part of Halfway Reach, and off mid-channel and then round Erith Bight.

4329. You know Erith Bight and all round there?—Yes.

4330. Can you tell us what the stuff that settles there is like?—Human dung.

*Mr. J. W. Showell.*

4331. Has there been any increase in that during the last few years?—A great deal.

4332. In the case of Barking what becomes of it?—Down along below Barking there is a great settlement of mud or filth, and right away to the lower part of Dagenham.

4333. Is the stuff that settles there like what you have told us in the other case?—Yes.

4334. Your duties are, I believe, to look after what comes into the river?—Yes.

4335. Can you tell us, from your own knowledge, what gas or chemical or other manure drainage comes into the river?—There is none that comes into the river, only through the sewerage.

4336. Is it a part of your duty to investigate anything that does come in?—Yes, it is.

4337. What would you do in the case of anything coming in?—I carry bottles, and I should take a sample from any works where I saw anything coming in.

4338. As a matter of fact, have you had occasion to do that during the last few years?—I have not.

4339. Therefore, in your opinion, is it true that chemical or manure drainage has killed the fish that used to be in the river?—I should think so; the sewerage.

4340. Due to what cause?—From the filth and that which comes through the sewerage.

4341. Can you tell the Commission how deep any of these deposits that you have told us about are?—I have let go my anchor, and I have found that there has been 8 or 10 feet in some places; I have not been able to reach it with my boat-hook.

4342. What has that been?—All slime and slush.

4343. What used there to be there years ago to your remembrance?—Hard shores.

4344. Do you know the chemical factories down the river in your district?—Yes.

4345. What are they, starting from Crossness?—There is only the factory belonging to Messrs. Price, the oil refiners.

4346. What are there above, between that and Barking?—There is nothing on the south shore. On the north shore there is the factory belonging to Messrs. Davis, the tar distillers, in Barking Creek; and that is all above Barking.

4347. Are you prepared to say that no refuse comes from them into the river?—I am.

4348. Had you anything to do with the Dutch eel-boats that used to come up the river?—I used to have to do with them.

4349. How many years ago is that?—40 years ago.

4350. Can you tell us from your own knowledge why they ceased to come up the river?—On account of the water going bad.

4351. How many years ago was that?—It is about 30 years since they first shifted.

4352. Where did they go then?—To Stoneness Point.

(*Chairman.*) We have had nobody called who says that he caught those eels or that he had to do with them, but it is all hearsay.

(*Mr. Balfour Browne.*) We propose to call the persons themselves.

Cross-examined by Mr. Bidder.

*Mr. J. W. Showell.*

28 Nov. 1882.

4353. What are your duties?—To see that there is nothing polluting the river.

4354. By whom are you appointed and to whom do you report?—The Thames Conservancy Office.

4355. How long have you held the appointment?—I have held the appointment of inspector for these six years.

4356. I believe you have other duties, have you not; such as superintending the removal of powder, and things of that kind?—I have to see it.

4357. You say that to your knowledge, since you have been inspector, there have been no offensive matters within your district poured in the river, excepting from the sewers of the Metropolitan Board?—That is all I have taken notice of in my travels.

4358. Do you know the Beckton Gasworks?—Yes.

4359. Are you aware of a sewer there?—I am aware of a large pipe there.

4360. What is its diameter?—I have not measured it.

4361. Is it about three feet in diameter?—I should think so.

4362. Is liquid discharged from that pipe into the river at the present time?—No.

4363. How long is it since any was discharged into the river from that source?—I cannot say; I have never seen any.

4364. Will you undertake to say that that pipe has not been discharging frequently during the present year?—Not that I have seen.

4365. When did you visit it last?—I was there last Friday.

4366. For the purpose of inspecting?—Yes.

4367. What was your business then?—Looking at other places, and different things.

4368. Do you go into that pipe?—No, I did not.

4369. When did you last inspect that pipe to see if anything was coming from it?—You can see the water, but you cannot walk to it in the mud.

4370. When did you last, in the discharge of your duties, inspect that pipe to see whether offensive matter was discharging through it into the river?—I was there about a fortnight ago.

4371. Did you go for the express purpose?—No.

4372. I did not ask you when you were in the neighbourhood of the pipe; but when you were there last what purpose were you there for?—To look at other things up and down along the shore.

4373. Being there, did you go in to inspect the pipe?—Not purposely.

4374. You simply passed it in the boat rowing along?—Yes.

4375. When did you go for the purpose of making an inspection of that pipe?—A fortnight ago.

4376. You say that you happened to be going on other business?—No, I did not.

(*Chairman.*) He said that he was going on a variety of business, and that as he was going he did inspect that pipe.

4377. (*Mr. Bidder to the witness.*) At what time of the tide was it?—It was about half-ebb.

4378. Was the pipe uncovered?—No.

4379. How could you, without going in for the purpose, the pipe being covered, casually passing by and being on other duty, tell whether the matter was discharging from that pipe?—By the colour of the water and the mud on the shore.

4380. Have you ever, during the present year I will say, gone to look at that pipe at a time when the water would permit of your seeing it for the purpose of ascertaining whether there was a discharge from that pipe?—I have.

4381. When?—On several occasions.

4382. When last?—I will not say exactly when last. I have walked there.

4383. This year?—Yes, this year.

4384. When did you go there last?—I cannot say what the date was.

4385. Was it in the summer?—In the summer, and since.

4386. Have you seen it at low water?—Yes.

4387. You have never seen anything discharging from it?—I have seen the water running from it.

4388. You told me before that you had not?—Nothing offensive, I said; but you can always see water running out of it.

4389. Since you have been appointed inspector you have never seen anything offensive coming from that pipe?—No.

4390. Have you frequently reported to the Conservators offensive discharges into the river?—No.

4391. Have you reported on any this year?—No.

4391*a*. Or last year?—No.

4392. Or the year before?—No.

4393. Have you ever reported on one?—No.

4394. In point of fact is not your time principally taken up in superintending the powder business?—No.

4395. Now as regards another matter; you have said that the sewage deposits are at several places, and I want to see whether I have rightly ascertained those places. Am I right in saying that one of them is a large bank on the south side of the river opposite to and below Crossness?—Yes.

(*Chairman.*) All this we have had. There can be no question of the existence of these mud banks, can there.

(*Mr. Beaumont Morice.*) Not at all. The point that I put was merely the composition of them, according to this witness's knowledge.

(*Mr. Bidder.*) I thought that mud bank question had been pretty well disposed of. The witness comes and gives evidence as to where the sewage deposits; therefore I ask him a question in order to identify the place with the mud banks which we have already discussed. That is surely a proper thing for me to do, in order to show that this witness is speaking of the same mud banks as the other witnesses.

(*Chairman.*) Of course.

(*Mr. Bidder.*) If it is taken that he is, I am perfectly content.

(*Chairman.*) I did not understand him to start any fresh mud banks upon you.

4396. (*Mr. Bidder.*) If that is clearly understood I am entirely relieved from cross-examining him any further upon that matter. (*To the witness.*) One question about the tides; have you ever made any experiments upon the tides?—No.

Examined by the Commission.

4397. (*Dr. Stevenson.*) What is the colour of the water that comes out of this pipe at Beckton?—We should see if there were any different colour in it from the pure water; it would soon show itself.

4398. Then it is not the water that comes out of the pipe that is of a different colour?—No; if it had any colour at all it would lie on the mud and you would see it.

4399. (*Chairman.*) You say that when you inspected this pipe last Friday week, or fortnight, it was under water?—Partly under water.

4400. Could you see anything coming out from the pipe?—No.

4401. Then how could you tell whether there was any noxious matter coming out?—The water was coming out; but the noxious matter would soon colour the water there.

4402. (*Professor Williamson.*) Can you tell me whether the pipe which you mentioned as coming from the Beckton works discharges water in dry weather as much as in wet weather?—Not so much in dry weather as in wet; it does not run so long.

Re-examined by Mr. Beaumont Morice.

4403. Do you know whether this pipe takes off the land drainage?—That is what it is for, for taking off the surface water, the land drainage.

4404. Do you know further whether what comes out is filtered before it comes out?—I do not know.

*Mr. J. W. Showell.*

28 Nov. 1882.

The witness withdrew.

Mr. William Evans called in, and examined by Mr. Beaumont Morice.

*Mr. W. Evans.*

4405. I believe you live at Woolwich?—Yes.

4406. And you are an under-waterman?—Yes.

4407. What are your duties on the river?—Our under-water work is grappling, dredging, and feeling for things, and putting dogs into the cast, and lifting the things from underneath the mud.

4408. To take it shortly, your duty is grappling for things in the river?—Yes.

4409. From the opportunities that you have of seeing it in carrying out your work, can you tell us what is the state of the river?—The state of the river is such that when I put my grapplings overboard, I cannot go but a very little distance before they are choked, and they are no good to me; there is so much filth underneath of all sorts.

4410. There is a lot of filth, is there?—There is a lot of filth, sewage sort of stuff, which is nothing but slime and filthy stinking mud; and when we move it, it is like a lot of oil on the top of the water, and you can hardly bear the stench of it in the summer time.

4411. Have you ever seen any worms?—I have. I have seen some long red worms, several inches in length on my grappling ropes, my boats' cables. It is not a fish-feeding worm, it is a long red worm that eats all the substance of the rope if it is in the water many days; it rots the rope.

4412. It is not a fish-feeding worm you say?—

4413. (*Mr. Bidder.*) It is a rope-feeding worm?—Yes.

4414. (*Mr. Beaumont Morice.*) That you find on the muck and stuff that comes up?—Yes, on the rope.

4415. Have you ever, in going up and down the river, noticed when the sewage comes out at the outfalls?—I have rowed by on a moonlight night, when I could see the clock, as near as I can say between one and two and three o'clock, and it has been about three hours flood; I have rowed from Grays Black-shelf after having laid to there about three hours; and by the time I wash up my nets and get under weigh, and get up to the sewerage, it is about half-flood, about two hours before high water, and the water coming out of this outfall has shoved my boat on one side.

4416. That you say is before high water?—Yes.

4417. Have you ever noticed the river, especially at low water, when steamers have been going up or down?—Yes, up.

4418. What has been the effect of steamers going up the river at that time?—I have seen a boat trying to anchor in the Government moorings, outside the "Fishguard," opposite the stairs, and I have seen that boat get aground. Where the channel is now, instead of being the south channel it is the north channel.

4419. (*Mr. Bidder.*) Where is this?—Right opposite the dockyard stairs at Woolwich, outside where the "Fishguard" lay, which lies at Greenwich now.

4420. (*Mr. Beaumont Morice.*) When the steamer was passing up was there any stench from the water?—She was aground.

4421. As the steamer passed up was there any particular stench or stink?—Yes, very bad indeed in the summer time; shocking bad, and as black as ink.

Cross-examined by Mr. Bidder.

4422. When was it that you saw the sewage coming out before high water?—That was, I think, in the latter part of last July twelvemonth.

4423. Where were you coming from?—From Grays Shelf, what they term Black Shelf, just below Greenhithe.

4424. Did you start from there at half flood?—About half an hour or three-quarters of an hour after low water.

4425. What were you doing there?—Catching shrimps on Grays Shelf.

4426. Do you know at what time it was high water that night?—I cannot exactly say, but I think it was between about three and four o'clock, or after that; it must have been about five o'clock.

4427. You do not recollect the day?—No, I do not. I had no occasion to take notice of the day.

The witness withdrew.

Mr. Frederic Bowreman Jessett called in, and examined by Mr. Beaumont Morice.

*Mr. F. B. Jessett.*

4428. I believe you live at Erith, and you are the medical officer of health for the district?—I am.

4429. How many years have you been there?—Between 12 and 13 years.

4430. During that time what has been the condition of the River Thames?—Of late years it has been very bad. When first I came there young men used to bathe off the end of the pier constantly at high tide, in the early morning, before they went up to London to their business. Now such a thing would be totally impossible.

4431. Why would that be impossible?—Because of the contaminated state of the river.

4432. From what cause?—Undoubtedly from the sewage from the outfalls.

4433. Has that been increasing much during the last few years?—Considerably.

4434. Have you ever had occasion to treat persons for illness caused by this matter?—I have. There are several cases that I could name in which, I believe, the illness has been chiefly owing to the contaminated state of the river. I remember one case in which a new man came down to the cutter "Spray," the Thames Police yacht, and he had not been on board above a week before he was seized with most violent diarrhœa and sickness.

4435. When was this?—About the spring or the middle of last year.

4436. (*Chairman.*) What was the man's name?—I cannot tell you his name from memory.

4437. (*Mr. Beaumont Morice.*) He was suffering from diarrhœa?—He was suffering from diarrhœa and vomiting.

4438. In your judgment was that due to the state of the river?—I treated him on board the yacht for some few days, and finding that he got no better, I removed him; and shortly after his removal, within a day or two, he got completely well.

4439. (*Professor Williamson.*) Had the man been sleeping on board the yacht?—He had.

4440. (*Mr. Beaumont Morice.*) And you removed him on shore?—Yes.

4441. (*Professor Williamson.*) Did he get better afterwards on shore, or did he continue to be sick?—He got better very shortly after being on shore.

4442. (*Chairman.*) And recovered?—And recovered.

4443. (*Mr. Beaumont Morice.*) Can you tell us of any other cases?—A number of men who have been working in the mud, moving the mud from the different wharfs, have come to me from time to time suffering from diarrhœa and sickness.

*Mr. F. B. Jessett.*

28 Nov. 1882.

4444. You have attended men at the ballast wharf too, have you not?—I have.

4445. And you say that their illness is due to the same cause?—I believe it to be.

4446. (*Chairman.*) What were those men from the ballast wharf engaged in doing?—Removing the mud from the ballast wharf to keep the way clear for the vessels to come up.

4447. (*Mr. Beaumont Morice.*) Can you say whether this has been so to any general extent with persons working upon the banks of the river?—We have never had any epidemic of it.

4448. But have there been many cases of it amongst persons who have been working upon the banks of the river?—A fair number; I will not say many, but there have been several cases.

4449. What is the condition of health of the parish of Erith?—It is very healthy.

4450. Can you account for its being very healthy, notwithstanding the state of the river?—I believe that there are several causes. I believe one cause is that it is entirely a new place; the cottages are nearly all recently built; and in Erith proper the greater number of cottages are drained; and lately we have closed nearly all the wells in the place, and they have the company's water laid on. Further than that, I think that the fact of the soil at Erith being a good sound gravel tends to the healthiness of the place. We have had a number of wells closed within the last six or seven years, because we had some cases of typhoid fever in the town, and we find that wells contiguous to the river are polluted with sewage. Of course I cannot prove it, but I have very little doubt that all those wells are tidal wells, that is to say, that at low tide the wells are empty and at high tide they are full; and I think it quite possible that where the water can run away through any chink, or what not, the sewage might soak back and so contaminate the wells close by the river.

4451. By virtue of your position as medical officer of health, I believe you have recommended the closing of many of these wells?—I have, of several of them. They have been analysed by the public analyst and condemned.

4452. (*Dr. de Chaumont.*) Were the cases of typhoid fever chiefly in the houses that had tidal wells?—Yes, chiefly. It is generally on account of cases of typhoid fever that our attention has been drawn to the state of the wells, and we have had the water analysed.

4455. (*Dr. Stevenson.*) What is the condition of the cesspools there generally?—In that district there are very few cesspools. In Erith proper the houses are nearly all drained. At Abbey Wood, Belvidere, and Northumberland Heath the houses are not drained.

4454. (*Dr. de Chaumont.*) Did typhoid fever occur to any extent in houses that had cesspools?—In some cases. At Northumberland Heath, for instance, the year before last there was a family that had typhoid.

4455. Was the proportion of typhoid larger in the houses that had the tidal wells?—Yes, undoubtedly; but we have not had any typhoid for some few years.

4456. (*Mr. Balfour Browne.*) When you say that you have not had typhoid fever there for several years, of what place are you speaking?—I am speaking of the parish of Erith.

4457. (*Mr. Beaumont Morice.*) How long ago were most of these wells closed?—Last year we closed six or seven, and we have closed, I suppose, every year, more or less. I daresay we have closed six or seven wells almost annually for four or five years past at any rate.

4458. Do I correctly understand that those were nearer the river side than others?—They were.

4459. The upper part of Erith, you say, is healthy?—I say the whole of Erith is healthy.

4460. Do you still think that the sewage passing down the river is likely to exercise an evil effect?—I have not a doubt of it. I, myself, have been yachting. Only last summer I went out yachting and on returning with the flood tide there were large masses of sewage, as large as the table in front of me, floating about; and ladies on the yacht were sick and could not eat their tea on account of the atrocious smell from those masses of sewage that were floating about in the river; and that was on the flood tide, and not on the ebb. I may say, on the early flood tide.

4461. (*Chairman.*) Where were you then?—Off Purfleet.

4462. (*Mr. Beaumont Morice.*) That is just down at the bottom of Erith Rands?—Yes.

4463. That was on the flood tide, you say?—Yes, that was on the flood, about last July, which was a very hot month.

4464. Have you often noticed this on the river?—Yes, I have, and especially on the mud at low tide. You see the gases bubbling up through the mud at low tide constantly.

Cross-examined by Mr. Bidder.

4465. There is no doubt, is there, that the health of all Erith at the present time is exceptionally good?—It is good, certainly; I will not say exceptionally good.

4466. Is it not exceptionally good in this sense, that it is better than the average of London?—I think not. I think last year, if you look at the Registrar General's returns, you will find that the whole of England was very much healthier than it has been for years.

4467. I am not asking you about the whole of England; but is it not the fact that the statistics show that the health of Erith is better than the average health of London?

(*Chairman.*) That will appear by the Registrar General's returns.

(*Witness.*) I know that the last year's returns were lower; but last year was an exceptionally healthy year. You must remember that Erith is a country place, and not a town like London.

4468. (*Mr. Bidder.*) You said that one of the causes to which you attributed the healthiness of Erith was that it is a new place, to a great extent?—New cottages have been built.

4469. Are you aware that a large proportion of the houses of Erith do not drain into the river at all, but depend upon cesspools?—I am aware that in some part of Erith they do.

4470. Would you be surprised to hear that the surveyor has told us to-day that 507 houses drain into the river, and 1300 do not?—But you must look at the map of Erith itself in order to understand that. If you take the town of Erith proper, you will find that nearly the whole of the town of Erith drains into the sewers, but just the outskirts of the town, the branches you may say, do not. The 1300 refers to the houses in Belvidere and Northumberland Heath.

4471. Do you make annual reports?—I do.

4472. Do you happen to have your last annual report here?—I have it in my pocket.

4473. Will you produce it?—With pleasure, if you will hand it back to me again.

4474. (*Chairman.*) Is that the original?—This is a press copy of the original.

(*Chairman.*) We must have the original, and then it will be put in.

4475. (*Mr. Bidder to the witness.*) Is it the fact that the death rate of Erith has been decreasing year by year?—It has not.

4476. What is the death rate in the last completed year, 1881?—It was a very low rate, 114 deaths.

4477. What is that per 1000?—I do not know that I can calculate that out at a moment's notice. In 1878 there were 147 deaths; in 1879 there were 165 deaths; in 1880 there were 165 deaths; and in 1881 there were 114 deaths. There was a great fall in 1881, but in the two previous years there was an increase.

*Mr. F. B. Jessett.*

28 Nov. 1882.

4478. Will you tell the Commission, if you can, the death-rate per 1,000 in each of the last three years?—I do not know that I can do that. It so happens that the number is not down here. I have only the year 1880, when the death-rate was 14·63 per 1000.

4479. Did you officially report the death-rate in 1880 to be 14·63 per 1000?—I reported in 1880 that allowing for an increase in population according to the usual rate ——

4480. (*Chairman.*) Was this report in writing?—It was in writing.

4481. (*Mr. Bidder.*) Did you report the death-rate of 1880 to be 14·63 per 1000?

(*Chairman.*) That will appear from the written report.

4482. (*Mr. Bidder to the witness.*) You will be able to give me that report hereafter?—Yes. If I had had notice that the question would be put, I would have brought it with me, but I had no notice to bring these papers.

4483. Can you remember whether, according to your judgment, the death-rate of last year works out at less than 14·63 per 1000?—Last year it was 11·1 per 1,000.

4484. Has there been a remarkable absence of cases of death from diseases which would be attributable to causes such as sewage contamination?—There has been a great diminution in all deaths from infectious diseases or typhoid fever, because the sanitary arrangements of the place are very much better than they used to be.

4485. The deaths from typhoid are very few, are they not?—Very few. I think last year there were only one or two.

4486. The deaths from diarrhœa are very few, are they not?—I cannot remember straight off.

4487. And there have not been many deaths from diphtheria, have there?—There has been only one death from diphtheria to my knowledge.

4488. You have told the Commission, as I understand, that in the case of the wells that have been closed you are inclined to attribute their polluted condition to a percolation of sewage from the river?—I have promulgated that as my opinion some years ago; in fact I reported it to the local board as my opinion.

4489. What wells were closed last year?—I can tell you by looking at my report; but I cannot tell you straight off the reel.

4490. Were they not principally wells in the cottages behind West Street?—I do not think that well was closed. If my memory serves me rightly, I wished to have that well behind West Street closed, but it was not closed.

4491. Where were the wells that were closed; were they not in the same neighbourhood?—No, they were not; they were more in the High Street, if I remember rightly.

4492. Are they all in the neighbourhood of the river?—Yes, all except those in Belvidere: those in Belvidere were not in the neighbourhood of the river.

4493. Are not most of these wells in immediate contiguity to cesspools?—Not to my knowledge; not the ones in Erith proper.

4494. The well in West Street unquestionably was?—Yes, the well in West Street was, but that was not closed, although twice samples were sent to the public analyst.

4495. Were any others analysed by the public analyst?—All of them that have been closed.

4496. Have you the reports, or have the local board the reports of the public analyst?—I think there are reports upon all of them.

4497. Which could be produced?—I have no doubt they could.

The witness withdrew.

Mr. Richard Armitage called in, and examined by Mr. Beaumont Morice.

*Mr. R. Armitage.*

4498. You live at Woolwich?—Yes.

4499. What are you?—A fisherman.

4500. How long have you known the river?—I was apprenticed when I was 16 years old, and I am 66 now; that would be 50 years.

4501. Do you remember the outfalls being opened?—Yes, perfectly well.

4502. Is there any difference between the river now and what it used to be before the outfalls were opened?—A great difference, indeed.

4503. In what respect?—We could catch fish at Woolwich 50 years ago, or less than that. Twenty years ago there were plenty of fish at Woolwich.

4504. (*Chairman.*) Used you to catch fish 20 years ago there?—Yes.

(*Mr. Bidder.*) Many days ago, when Lord Bramwell was in the chair, I told my learned friend that I admitted that fish could be caught in that reach formerly and that they were not caught now, and we were told that that was an end of it.

(*Mr. Beaumont Morice.*) I know that the matter with regard to the fishing is done with. I am only going to ask the witness one question as to a date.

(*Chairman.*) I understand the admission to be that there used to be fishing up the river in the direction that the witness speaks of, and that now no fish can be caught there.

(*Mr. Bidder.*) That it used to be worth fishing, but that now it is not; I do not say that there are absolutely no fish.

4505. (*Chairman, to the witness.*) Practically, are there any fish above Gravesend?—No, we cannot get any fish above Gravesend.

4506. (*Mr. Bidder.*) It does not quite go so far as that; but practically for a considerable distance the river is not worth fishing?—Since the outfalls have been opened, there have been no fish. There are no fish this side of Gravesend. If they do come any higher up than Gravesend, they get killed by the sewage water.

(*Mr. Bidder.*) The last witness but one had been on a shrimping expedition at Grays.

4507. (*Mr. Beaumont Morice.*) And another tried to fish and got nothing.

(*To the witness.*) When did you find that you could not get any more fish in the old fishing grounds?—We have done no good in the way of fishing since the southern outfall has been built.

4508. (*Chairman.*) You have done no good there?—Not this side of Gravesend, not to get a good living, since the southern outfall was opened. We used to get a good living off Erith.

4509. (*Mr. Beaumont Morice.*) What is the state of the water at the present time down the river?—Very bad; very black indeed at certain times of the tide.

4510. Is there any smell or stench from it?—Yes, very bad indeed.

4511. You know the mud stuff along the banks, what is that like?—The settlements along the shore are quite black, and of a slimy nature.

4512. Is that only at one part, or does it extend away down?—At Long Reach it is very bad indeed; that is just above Greenhithe.

4513. Are there any other parts?—At Erith in particular; that is the worst place there is. There are solid banks of mud rising up there 7 or 8 feet high.

4514. Anywhere else up the river?—Yes; there is the northern outfall in what they call Gallion's Reach.

4515. Are there any more of the deposits of mud that you have been talking of further up than Erith Reach?—Oh, dear me; Yes.

4516. Where?—At Dagenham in particular.

4517. Then you say that all the way from Dagenham, round Erith, through Erith Bight, and down Long Reach there are these deposits?—Yes.

4518. Have they increased during the last few years?—Yes, they have increased very much indeed.

*Mr. R. Armitage.*
28 Nov. 1882.

4519. Is it ordinary mud, or what is it like?—What used to be bright mud is now quite black.

4520. Do you know how far anything will go down on the ebb tide if it is put in, say, at Crossness?—Yes; it might drive to Gravesend.

4521. Have you ever tried anything of the kind?—No, I have not; but I should judge that that is where it would drive to.

4522. Do you know whether the deposit stuff settles in the river, or whether it is carried down?—All the thickest of it settles along the shore, and nothing can live nigh it. It has killed all the red worms in the mud and all the bright worms; and there is no food for fish. If the fish came up they could not live.

4523. Do you know where it settles?—Yes; off Jenningtree Point and off Dagenham Docks.

4524. And all the way down the river?—From the northern outfall downwards.

Cross-examined by Mr. Bidder.

4525. You find no worms now in the mud?—No.

4526. No long worms that feed on rope or anything else?—No; there is nothing for them to eat now.

4527. If anybody says that they find long red worms in the mud of the river now they are talking nonsense?—That is wrong; there are none this side of the Lower Hope now. I have looked after them; in fact, we used to get them for bait at one time.

4528. And you cannot get them now?—We should be very glad to find them now.

4529. You used to fish above Gravesend?—Yes, but we cannot do so now.

4530. What did you get?—Shrimps, flounders, eels, and smelts.

4531. Where do you sell your eels?—I generally bring them to Erith.

4532. How do you take them?—In a corfe.

4533. You do not put them in the water?—No.

Examined by the Commission.

4534. (*Chairman.*) Have you ever tried any grappling in the mud?—Yes; occasionally we go grappling and dredging.

4535. In grappling you have never found any long worms?—No; if it is only a bit of rope, anything that we pick up on the grapnel is all black and slimy.

The witness withdrew.

Mr. James Adams called in, and examined by Mr. Beaumont Morice.

*Mr. J. Adams.*

4536. You live at Grays?—Yes.

4537. That is on the north shore?—Yes.

4538. And you are master of the barge C.T.F.?—Yes.

4539. How long have you known the Thames?—40 years and over.

4540. Will you tell us what difference there is in the state of the river, if any, between 30 years ago and now?—Yes, I can. Years ago, before the Crossness Outfall was built, I have seen ships lying just below there, colliers drawing from 14 to 15 feet of water.

(*Mr. Bidder.*) I have admitted long ago, formally, that banks have grown up at Crossness, and at Dagenham, and at Barking, which were the subject of the previous arbitration.

4541. (*Mr. Beaumont Morice to the witness.*) What is the condition of the river now?—There are not 5 feet of water.

4542. What kind of water is it?—Very bad indeed; filthy.

4543. In getting your anchor and chain up, do you find anything on it?—It is smothered with filth; there is nothing but sheer matter on it; it takes us half our time to sluice it with water to get the muck off it.

4544. Is there any smell about it?—Oh yes, enough to knock you backwards; dreadful.

4545. In going up and down the river have you ever noticed at what time the sewage comes out of the outfall?—At about half flood; about three hours before high water.

4546. (*Chairman.*) You have noticed that?—Yes, plenty of times.

4547. (*Mr. Beaumont Morice.*) Can you tell us, from your own knowledge, how far sewage coming out at half-flood would go up the river?—I should think it would go to Blackwall.

4548. Have you ever tried how far it would go up?—No; but we know by letting go our anchor, and getting our anchor, by the chain.

4549. Have you noticed whether this stuff in the river settles down, or whether it goes out to sea?—It goes away down.

4550. Where does it go to?—It would go as far as Long Reach, I should think, below Purfleet.

4551. Can you tell us how far it would come back on the flood?—I do not know that I could do that.

4552. Does this stuff affect the paint on the barges at all?—Yes; we frequently bring up at Crossness, which is an anchorage for us, and it turns the paint all manner of colours when we lie there, because we lie there seven hours ebb when we bring up at high water.

Cross-examined by Mr. Bidder.

4553. What is your business principally?—Carrying cement from Purfleet to the Docks and the Pool.

4554. When did you see the sewage coming out at half-flood?—I see it frequently; some two or three times a week.

4555. When did you last see it coming out at half-flood?—It was dark when we last came by; but we saw it about a fortnight ago.

4556. You saw it coming out at half-flood about a fortnight ago?—Yes.

4557. At what time in the day or night?—In the afternoon.

4558. Were you going up on the tide?—No, coming down.

4559. With your barge?—Yes.

4560. And you saw the sewage coming out?—Yes.

4561. What sort of barge is yours?—She will carry 80 tons.

4562. Is it a rowing or a sailing barge?—A sailing barge.

4563. Are you accustomed to come down then on the flood tide?—Yes; we come down at all hours of the night and day, just as the tide suits.

4564. The tide would not suit if it were half-flood, would it?—We come over the tide with a fair wind frequently.

4565. Where were you coming from?—We were coming from Beckton.

4566. Would you mind fixing a little more definitely what time of day it was?—I should think it was about 3 o'clock in the afternoon, but I would not be sure.

4567. Do you recollect at what time it was high water that day?—I almost forget now about what time it was. I could refer back and see if I had an almanac.

4568. What did you see on that occasion?—It seemed like nothing but grease.

4569. Where?—I should think 100 yards away all round from the sewer where it comes out.

4570. Did you look at the outfall itself?—Yes; we could see the pumping out; we could see it coming right out.

4571. In large quantities?—In large quantities; it would take your barge away from your helm.

4572. You say that this was at half-flood?—Yes.

4573. And about a fortnight ago?—Yes.

4574. (*Mr. Beaumont Morice.*) That is not the only time you have seen it?—No; I have seen it more than once.

4575. (*Mr. Bidder.*) Do you know the sewer at Beckton?—Yes.

4576. Have you ever seen anything going out of that?—Yes. It is in a frightful state; it is just as bad off the sewer there as it is in Half-way Reach.

4577. Is the stuff that comes from that sewer offensive?—Yes; if you let go your anchor it is just the same as it is at Crossness.

4578. (*Chairman.*) What do you mean by Beckton?—The gasworks, just below where the sewer is.

4579. (*Mr. Bidder.*) You have seen the stuff coming from the sewer?—Yes.

4580. And it is offensive?—Yes.

4581. Does it come in considerable quantities?—Yes, and it is just as bad as it is at Crossness.

4582. (*Chairman.*) Do you say that there is a sewer at Beckton?—Yes, a pumping station; it comes out of there.

4583. At Beckton?—Just below Beckton.

4584. (*Mr. Bidder.*) You are speaking of the northern outfall?—Yes.

4585. Do you know the Beckton Gasworks?—Yes.

4586. Do you know the sewer pipe that comes out there?—I never noticed it.

The witness withdrew.

Mr. Thomas Brown called in, and examined by Mr. Beaumont Morice.

4587. Do you live at Gravesend?—Yes.

4588. And I think you are the master of one of Messrs. Knight, Bevan, and Co.'s barges?—Yes.

4589. How long have you known the River Thames?—Forty-four years I have been master of a barge running from Northfleet to London.

4590. Do you remember the outfalls being made?—Yes.

4591. Can you tell us if there has been any difference in the state of the river between what it was before that time and what it has been since?—I know that ships lay afloat in 12 to 13 feet of water in Half-way Reach where I cannot now lie afloat with my barge.

4592. What is the state of the water itself?—It is in a most filthy state; nothing but impure matter. My cable and the anchor when I heave it up are blacker than my clothes.

4593. Where are you talking about now?—Half-way Reach.

4594. Do you find this impure matter and filthy stuff in other parts of the river as well?—In Erith Reach as well.

4595. What is the colour of the water?—As black as ink.

4596. Is there any smell to it?—Yes; enough to knock you down when they let the water out of the sewer.

4597. When have you noticed the sewage coming out of the outfall?—Two hours before high water in Half-way Reach.

4598. Have you noticed that more than once?—Scores of times. As soon as we come from Beckton with coke we catch it there, as it comes out, and it slews my barge all on one side.

4599. Is there any alteration in the colour of the water in the river when it comes out?—Yes.

4600. What is it like then?—It is nothing but a body of grease at the top, and underneath it is quite black, of a different colour altogether from the other water.

4601. Can you trace that down the river at all?—I have traced it down as far as below Erith.

4602. Have you ever followed it down on the top of the ebb?—That is when we very often come down, and sometimes we are two or three hours before high water, and it will follow us down, looking as black as my clothes.

4603. Have you ever started at the top of high water and gone with it as far as it went?—No, because we have no occasion to go any farther than our destination.

4604. You have gone as far as where?—To the Northfleet works, Messrs. Knight and Bevan's.

4605. Have you traced the sewage there?—No; I do not find a great deal in Northfleet Hope, not at the anchorage.

4606. Do you know the banks of the river all up and down on the south shore?—Yes.

4607. What is the stuff that is deposited there like in popular language; is it mud?—It is nothing but stinking filthy matter.

Cross-examined by Mr. Bidder.

4608. You apply that description, as I understand, to the mud off Crossness?—I apply it to what comes from the common sewer which causes this matter to be lying in the bottom of the river.

4609. Do you mean off Crossness amongst other places?—What was in Barking Shelf might come from the north side.

4610. When you describe the mud in that way, you are speaking of the mud that is in Half-way Reach off Crossness?—There is not such a great deal of mud there now, because just as you go below the creek in Half-way Reach it is all stonework; the wall is all stone.

4611. Where you used to have a great deal of water you now anchor, and you find that there is a great deal of mud and it comes up filthy on your anchor; that is off Crossness, is it not?—Yes.

4612. And you describe that mud as being what you said?—Yes, I do.

4613. What kind of barge is yours?—A 90 ton barge.

4614. Is it a rowing or sailing barge?—A sailing barge.

4615. Is it your business frequently to go down to Beckton with coke?—We load from there every freight.

4616. Have you noticed a sewer pipe at Beckton?—No; there is an outfall there.

4617. Did you ever see anything coming out of it?—Yes, but it is clear water; it is clearish water.

4618. Have you ever smelt anything coming from it?—Well, I cannot say that it is altogether sweet.

4619. Is it offensive?—It is not very pleasant.

4620. What sort of a smell is it?—It is not so bad as the sewer.

4621. "Comparisons are *odorous*" they say; but what sort of smell is it?—I cannot exactly tell you what sort of smell it is; it is not very pleasant.

4622. What sort of colour is the water that comes from it?—It is rather a muddy colour; there are no settlings in it. The water that comes from there is clear, but it is a kind of yellowish colour.

4623. Have you seen it lately?—Not the last fortnight.

4624. This summer?—Yes.

4625. Often?—Yes, and last summer.

4626. And you have complained of it, I daresay?—We must not complain of such things as those.

4627. You said, as I understand, that not long ago you went down with a cargo of coke and saw the sewage coming out of the Barking Outfall?—No; in Half-way Reach.

4628. Was it the Crossness Outfall?—Yes.

4629. How long ago was that?—It would be a fortnight ago to-morrow.

*Mr. T. Broum.*

28 Nov. 1882.

4630. That would be the 15th of November. What time in the day was it?—That was in the night.

4631. What time in the night?—About 11 o'clock, I think.

4632. You saw the sewage coming out of the outfall?—It will tell you itself when it comes out, because it throws the barge on one side by the force of it.

4633. Did you see it coming out of the outfall?—I could tell that it was running out.

4634. Did you see it coming out of the outfall?—Yes.

4635. There was no moonlight, if I remember rightly, a fortnight ago?—No.

4636. Do you know at what time it was high water?—About 1 o'clock.

Re-examined by Mr. Beaumont Morice.

4637. You say that you know by its slewing the barge round?—Yes; it is so strong when it comes out that we have to put the rudder over to port to keep her straight.

4638. Why do you not complain of such things as these?—It is not in my power.

4639. But it is not because you do not smell them?—No.

4640. What do you mean by saying that the water from this pipe at Beckton is clear, but yellow?—It goes through some process before it comes out into the river, and that turns the water a different colour. It comes from the tar or something.

4641. You say it is of a yellow colour, but clear?—Yes, there is nothing in it that I can see.

4642. What do you mean by saying that there is nothing in it?—No settlings.

Examined by the Commission.

4643. (*Chairman.*) You said that you could tell that sewage was coming out because it slewed your barge?—Yes; it comes out with such force.

4644. Then it was because your barge was slewed that you knew it was coming out, and not that you actually saw it coming out?—No; the pipes are under water. I cannot see it, but I can tell by the water.

4645. You supposed that it must be that because you felt your barge slew round?—Yes.

(*Mr. Bidder.*) It may interest the Commission to know that it was close upon dead low water at the time the witness mentions.

4646. (*Chairman to the witness.*) Was this at Crossness or at Barking?—I cannot tell you that. If I had known that I should have been asked these questions I might have brought my notes from the office.

4647. You are sure that it was a fortnight ago to-morrow?—No, I am not certain, because we do not take any notice of particular dates; but if I had known it I might have got my notes.

4648. (*Dr. Stevenson.*) What is the difference between the tide there and at London Bridge. If it was low water at half-past 4 at London Bridge, at what time would it be low water at the point you mentioned?—There would be about 40 minutes difference, I should think.

(*Mr. Bidder.*) There would be about half-an-hour's difference.

4649. (*Mr. Beaumont Morice to the witness.*) You are going up and down continually?—Yes.

The witness withdrew.

Mr. Robert Plumb called in, and examined by Mr. Beaumont Morice.

*Mr. R. Plumb.*

4650. You live at Gravesend, I think?—Yes.

4651. How long have you known the River Thames?—About 47 years. I am 57 years old, and I was at work with my father when I was 10 years old.

4652. During those 47 years has the river improved in its condition?—Well, we have to go further away after the fish.

4653. At what time did you have to remove further down the river for your fish?—Some 12 or 14 years ago, as nearly as I can remember. We used to go up to the top of Long Reach, and stand with what we called a sprat net, after eels. That was when we used to go up there. There used to be plenty of eels then up at the top of Long Reach.

4654. (*Chairman.*) Did you fish for them 14 years ago?—Yes. When the dead tides used to be the water was pretty middling, so that the eels would be between the two waters. As soon as the spring tides began to come, then down came the bad water, and we could not get any more eels, and we used to have to sweep them out of the wells to save their lives.

4655. (*Mr. Beaumont Morice.*) How many years ago is that?—That is 12 or 14 years ago.

4656. Can you tell us which is the stronger of the two tides, the flood tide or the ebb tide?—The ebb tide, I fancy, because there is more slack water on the flood tide round the points.

4657. Have you ever seen yourself how far anything would go down the river on the ebb tide, supposing you put it in at Crossness?—We know by the drive of the gear. I can go by where I drive with the tide.

4658. You have never tried yourself how far you would go down with the tide?—Only by the drive of the gear. We drive with the tide with a trawl overboard, and we can drive from Gravesend to about Leigh Middle; but then there is no tide on the bottom, scarcely.

4659. Is there any difference between the flood and the ebb as to the strength of the tide at the top and the bottom?—I do not think there is much. There is more slack at the top of the tide on the flood round the points than there is on the ebb.

4660. Where do you fish and get shrimps now?—Mostly in Sea Reach. Sometimes we have got a few in Gravesend Reach this summer, but very few. Sometimes we go down to where the Cutter in the Hope is.

4661. You get them in Sea Reach?—Yes.

4662. Have you to do anything with them before bringing them up to Gravesend?—We boil them.

4663. Why do you boil them?—Because we cannot keep them alive.

4664. Could you keep them alive in the water?—At one time of day I have laid off Gravesend with 20 gallons in the well all night.

4665. Why can not you keep them alive in the water?—Because as soon as you shoot them in the well now down they go, and they never rise any more, because the water is so bad.

Cross-examined by Mr. Bidder.

4666. I suppose you do not know the reason of their dying?—I know that the water is bad.

4667. How do you fix the 14 years which you have given us?—I say 12 or 14 years.

4668. How do you fix it?—I do not know what you mean by "fixing it."

4669. What makes you able to say that it is 12 or 14 years?—I know it is. You do not think I am such a dunce as not to know that.

4670. I have not said so yet?—I know it by the time that I have been on the water.

4671. You have been 47 years on the water?—

Yes; I have got boats of my own, and I know when I bought them and how old they are.

4672. You are more than 14 years old?—Well, I rather think I am.

4673. I understand you to say that you used at one time to catch them at the top of Long Reach, and that now you go further down. Are the fish brought up in the water now?—You cannot keep them alive as far as Gravesend.

4674. Nothing will live beyond Gravesend?—No.

4675. You never heard of the eel boats going up with the eels in the water?—They used to at one time of day, but they take the eels up in boxes in the boat now from Hole Haven; they would not live in the water.

4676. You have seen that?—Yes; always for these several years; I do not know how many years; ever since they have been down at Hole Haven.

The witness withdrew.

Mr. George Martin called in, and examined by Mr. Beaumont Morice.

4677. I believe you live at Gravesend?—Yes.

4678. I believe you are a free waterman?—Yes.

4679. How long have you been on the river?—Ever since I was 10 years of age.

4680. For about 40 or 50 years, I suppose?—I am now between 57 and 58 years old. I was born in 1824.

4681. You have known the river for nearly 50 years?—Yes.

4682. Do you remember the outfalls being opened?—Yes.

4683. Is there any difference between the state of the river now and what it was then?—Yes, very much.

4684. In what way?—I remember when we could well drink the water of the river at any time of the tide previously to these outfalls being opened.

4685. (*Chairman.*) At Gravesend?—No, in Halfway Reach and Barking and along the river. We used, when I was a hatch-boat boy, carrying the fish out of the smacks, to fill our water cask up there.

4686. (*Mr. Beaumont Morice.*) That you have not been able to do for some time?—No, not since the outfalls have been opened.

4687. Is there any alteration in the state of the river?—It very much fills up with mud and slush and muck, and it is in a filthy state.

4688. Is there any smell?—It stinks filthy.

4689. And is the stuff, which you say is on the banks of the river, mud, or what is it?—I do not know what to call it; it does not look like mud; it looks more like filthy muck.

4690. Has there been any alteration in that in the last few years?—It is very bad compared to what it was some few years ago; it is quite a filthy stench.

4691. Have you ever noticed when the sewage is coming out of the outfalls?—I have never seen one of the outfalls opened but once since I have been up and down the river, and that has been on high water, or sometime just before high water; and then I know the stench of it was something horrid.

4692. Is there any difference in the colour of the water?—It is as black as a coal.

4693. Have you been able to trace how far it goes down the river?—I have never known how far it goes down?—I have smelt it about as far down as Erith and Long Reach.

4694. Can you tell us how far anything goes down on the ebb tide if it is put in at Crossness?—I should think, according to my own mind, to about Gravesend Reach.

4695. Have you ever tried anything which would show that?—No, I have never had an opportunity of doing that.

4696. Do you know the fishing that takes place by Gravesend now?—I know but very little about fishing. I have never been in the habit of catching fish I have been in the habit of carrying many fish.

4697. Where do you carry them principally?—From Gravesend to Billingsgate.

4698. (*Chairman.*) Do you do that now?—Yes; I come up with fishing smacks from Gravesend, where I take charge as waterman down to Billingsgate.

4699. (*Mr. Beaumont Morice.*) How long have you carried them up from Gravesend in that way?—I should suppose about 38 years and over.

4700. Have you ever tried to bring the fish up in the well of a boat?—I have seen them brought up in what they call corves; things which are made like a boat full of holes on purpose to keep them in, like a trunk; but that is some years ago.

4701. How many years ago?—I suppose it would be 16 or 17 years ago.

4702. Is that done now?—No.

4703. Are you quite sure about that?—I am positive.

4704. Can you tell us why it is not done?—On account of the water; the fish would not live, the water is so bad; but I have noticed up as far as Greenwich that the water has been very good there lately, I suppose on account of the fresh water.

4705. That is in the upper part?—Yes, but below that it is very bad.

4706. Can you tell us whether below that it has been getting better or worse lately?—Really I could not tell you that; but I know it is very bad from Halfway Reach down to Erith and Purfleet.

4707. Can you tell us whether it makes any difference to a fisherman sending fish up by water or by rail?—I should imagine that it did, because I remember that some few years ago they used to bring fish to Gravesend and they used to be in the well for two or three days; but now they cannot do so.

4708. Do you know whether it is more expensive to send fish up by rail?—Yes, a deal more expense.

Cross-examined by Mr. Bidder.

4709. Do I rightly understand that you have been for 38 years engaged in taking fish from Gravesend to Billingsgate?—Yes.

4710. In your boat?—No, in a fishing cutter. They go to the North Sea, and they have the fish put into the vessels there, out of the vessels that catch them.

4711. Are you still engaged in that business?—No.

4712. Are those fish alive?—No, they are all dead and packed.

4713. They are dead long before they get to Gravesend?—Yes.

4714. And they are brought up in the hold of the vessel?—Yes.

4715. You are not a fisherman?—No, I am a waterman.

4716. You have nothing to do with the live fish?—No.

4717. When you said that the river was very bad from Halfway Reach to Gravesend, what is it exactly that you had in your mind?—No more than that the water is bad and smells beastly; that is all that I have in my mind, and I could prove it.

4718. The Commissioners could go and smell it all the way down to Half-way Reach?—I believe they could.

4719. As far as Gravesend?—No, I do not say that; I say as far as Long Reach.

4720. You say that the fish will not live if they are

*Mr. G. Martin.*

28 Nov. 1882.

brought up to Billingsgate in corves now?—I do not believe they would.

4721. Eels would not live?—Yes, and I will tell you how they live. They bring them through Halfway Reach with a tug, and directly they get above Halfway Reach or to Greenwich they have the water pure. They are in the wells on board the vessels.

4722. (*Chairman.*) So that they get the river water there?—Yes, they get by Halfway Reach as quickly as possible, on the low water if they can, and then they get clear of that water that is so bad.

4723. But they do come through Halfway Reach and carry them up to Billingsgate at the present time?—Yes.

4724. (*Mr. Bidder.*) And they come up alive?—Yes.

4725. And that has been done very lately?—Yes.

4726. (*Mr. Abernethy.*) Is that a common way of bringing fish up?—Eels in particular.

4727. (*Colonel Ewart.*) Would that be done in summer?—I believe so.

4728. (*Mr. Balfour Browne.*) Have you seen it done?—Yes, I have, or else I could not say so.

4729. (*Chairman.*) What did you say about their coming up at low water?—If they can get by there at low water, before any of this stuff is poked out, as I term it, they do not feel the effect of it as they would if it came out on high water. I have known it push boats on one side when it has been coming out.

The witness withdrew.

Mr. John Tall called in, and examined by Mr. Beaumont Morice.

*Mr. J. Tall.*

4730. You live at Gravesend, I think?—Yes.

4731. And you are a waterman and lighterman?—Yes.

4732. How long have you been on the river?—About 36 years.

4733. You remember when the outfalls were made?—Yes, well.

4734. Has there been any difference between the state of the river before and since?—A great deal.

4735. In what way?—It is worse, a great deal.

4736. What is the river like now?—It is dirty, filthy, black mud.

4737. Is that at one particular part or at different parts?—Between Erith and Woolwich, principally.

4738. Can you tell us what it is like?—The mud is thick black mud.

4739. Is it like ordinary mud; is there anything that you can tell it by?—You can tell when you get into where the drainage is by the chain that you ride by.

4740. How can you tell it?—Because it turns the chain black.

4741. Is there any smell to it?—Yes, it stinks very much; it has a very nasty smell.

4742. Have you been up the river at any time when the sewage has been coming out?—Yes, a great many times.

4743. Have you noticed what time of the tide it has been coming out?—I have not taken notice of any particular time. I have never passed it without seeing it coming out.

4744. Can you give us from your memory what time of the tide it was when you saw it coming out?—I have been in the habit of passing it at all times of the tide. I have been up and down the river six times a week; so that I have occasion to pass there a great many times.

4745. Have you noticed the mud and stuff up and down the banks of the river?—On the shores.

4746. What is that like?—It is a soft slough stuff.

4747. Is it mud?—It is more like slime.

4748. Is there any smell from that?—Yes.

4749. Has it been increasing lately?—It has been increasing fast.

Cross-examined by Mr. Bidder.

4750. The smell or the mud?—The mud.

4751. In Halfway Reach?—Yes.

The witness withdrew.

(*Mr. Bidder.*) You will understand that although I do not ask this gentleman any questions upon his evidence as to the mud, I do not admit that it is correct.

Mr. William Brown called in, and examined by Mr. Beaumont Morice.

*Mr. W. Brown.*

4752. You live at Gravesend, I think?—Yes.

4753. And you are a fisherman?—Yes.

4754. How long have you known the river?—56 years. I have been master of a little fishing boat.

4755. Do you remember the outfalls being made at Barking and Crossness?—I do perfectly well; but I cannot tell you how long ago it is.

4756. Has there been any alteration in the state of the water since the outfalls were made?—A wonderful sight of difference.

4757. (*Chairman.*) For better or for worse?—For worse.

4758. In what respect?—As far as my knowledge goes, we could get a living in the winter seasons.

4759. But how is the river worse?—Because nothing in the world will go up into it to breed.

4760. But what is the matter with the river?—That is a question I cannot answer, because I cannot tell what goes into it.

4761. You say it is worse?—It must be if nothing will live in it.

4762. It does not look worse, does it?—You cannot see it on the top so much.

4763. Is it the ordinary colour?—When it is hot weather you can see a difference.

4764. Is the water the same colour as it used to be?—I do not know that I can exactly say.

4765. Has it the same smell as it used to have?—I do not know that it ever had a smell.

4766. Has it a smell?—Not to my knowledge. I have not been up the river above Greenhithe for some time.

The witness withdrew.

Mr. Henry Evans called in, and examined by Mr. Beaumont Morice.

*Mr. H. Evans.*

4767. You live at Woolwich, I think?—Yes.

4768. What are you?—I am an under-waterman and sand dredger.

4769. How long have you been there?—All my life.

4770. Do you remember the outfalls being opened?—Yes.

4771. Has there been any difference in the state of the river since that time?—A vast deal.

4772. In what way?—In regard to the refuse and

rubbish at the bottom of the river, and likewise the sand that we dredge, sometimes with dredging irons and sometimes with a shovel. At Jenningtree Point, which I used to frequent nearly every day in the week 30 years back, the sand was always very good and clear, but of late years it has been very filthy and dark. There was a kind of streak of sand and then a streak of greasy black mud, and it was scarcely any use to us; and in warm weather we could scarcely stand to our tools to work it for the stench and the refuse under the bottom of the sand.

4773. Have you been up and down the river much?—Ever since I was a boy, two or three times a week.

4774. Can you tell us at all whether you ever noticed when the sewage comes out of the outfalls?—Yes, at the southern outfall in particular. I have been rowing down from Woolwich, say, two hours before high water, and when I have got down about Barking Creek round by Tripcock Point I have seen the water coming up when it has been blowing a little breeze, a little roughish on one side and the other side smooth, and it was the stuff lying on the water that caused the smoothness. It was broken water on the north side, and on the south side it would not break. We always work up this greasy water because it is smooth water.

4775. And you have noticed that more than once?—Frequently I have noticed it come out two hours before high water.

4776. How often do you go up the river?—Sometimes four, sometimes three times a week, and sometimes every day in the week, according to what we have to do.

Cross-examined by Mr. Bidder.

4777. You have been going down the river, and you have noticed that one side of the river was roughened by the wind and the other side was smooth?—Yes, at times.

4778. And you attributed that to the greasiness which came from the sewers?—Yes.

4779. And you inferred from that that the sewage was coming out?—I have been there when the current from the sewage has driven my boat away.

4780. What sewage?—The sewage from the southern outfall.

4781. You told my learned friend that this was at half flood?—Two hours flood. It takes me half an hour to row down from Barking Creek to Woolwich; it would be about an hour and a half's flood by the time I got to Barking.

4782. And then, seeing the greasiness made you believe that the sewage was coming from Crossness?—Yes, because I never found it before the outfalls were built

4783. (*Chairman.*) Have you ever perceived any smell in the river?—Yes.

4784. What kind of smell?—Very bad; it is a very sickly smell, especially by Barking Creek up to what you call the northern outfall.

The witness withdrew.

(*Mr. Beaumont Morice.*) Bearing in mind what I mentioned at the commencement of the sitting, perhaps the Commission might like to hear some statement from me as to the course which I propose to take. I have a very large number of witnesses; I do not say that they are all exactly like those that have been called to-day, but some of them are persons resident in the locality, and others are actually connected with the river. The further evidence that I can bring forward on behalf of the memorialists will to a great extent be on the same lines as that which I have already put before the Commission. I admit that to a large extent it has been repetition, and I have felt that the Commission have been very kind to listen to it; but of course the essence of my case here is that the evil is widespread, and is felt by a large number of persons. Beyond that, I, on behalf of the memorialists, am not prepared to go. With regard to the chemical evidence and matters of a more abstruse kind, that of course will involve a large expenditure of money, which the memorialists have not been able to undertake, and those questions I believe will be dealt with by my learned friends who represent the City authorities. That being so, I would wish to leave the matter in the hands of the Commission. Perhaps by my formally tendering a large body of evidence which I have still remaining, not wishing thereby to be considered as closing my case simply upon that evidence which I have brought before you, the Commission might see their way to throw out some intimation to me with regard to the desirability of having some further evidence upon any point.

(*Mr. Bidder.*) You will hardly ask the Commission to commit themselves to any opinion upon the point.

(*Mr. Beaumont Morice.*) I do not ask them to commit themselves.

*The Commission deliberated.*

(*Chairman.*) The feeling of the Commission, Mr. Morice, is that a continuance of this kind of evidence would not strengthen your case in any way. If hereafter the evidence of these people should be seriously contested; if it should be shown that there are no grounds for holding that the river is unpleasant to those who are upon it, not as a question of healtht but simply as a question of comfort, we should, no doubt, give you an opportunity of calling further evidence; but to go on heaping witness upon witness upon the same point would not, I think, strengthen the case which you have at present made. It will now be for your adversaries to deal with it, and if that case should be shaken you shall have an opportunity of calling further evidence.

(*Mr. Beaumont Morice.*) I am much obliged to you, sir. That is all I wish for in the matter. I have a large body of evidence, not only of witnesses similar to those whom I have called, but of persons in a different position of life; but I am quite satisfied with the intimation you have given, and therefore I will reserve myself.

(*Mr. Bidder.*) I think it is right that I should say at once that it will be strongly contested, in the evidence that I shall call, that the state of the river is such as to seriously interfere with the comfort of the people living or trading on the river. It seems to me, as I intimate to my learned friend now, that if there is any further evidence to be got upon that point, which is material, now is the time to bring it forward, because then I know what case I have to meet, although, if I may respectfully say so, I entirely endorse the views of the Commission that merely repeating witness after witness of the same kind does not add to the strength of the case. I am willing that it should be taken as assumed, as I have no doubt is the case, that my learned friend could call 20 or 30 or 50 more witnesses who would, with the same sincerity of belief, give practically the same evidence as those who have already been called; but I confess that I should like to hear the whole indictment against me, because I am put on my defence.

(*Chairman.*) With respect to what has fallen from Mr. Bidder as to its being an indictment, the fact is, we are here merely as a court of inquiry. Mr. Bidder's clients are not upon their defence. We are all engaged in one common cause, and every witness that Mr. Morice calls is Mr. Bidder's witness, and every witness that Mr. Bidder calls is Mr. Morice's witness.

*Mr. H. Evans.*
28 Nov. 1882.

We must look upon it in that light. But I still think that the feeling of the Commission is that you, Mr. Morice, have started a sufficient *primâ facie* case. If it should be shown that your witnesses are really mistaken, or that they are misleading us, we shall give you the opportunity of calling any further evidence that you may think necessary.

(*Mr. Beaumont Morice.*) I am much obliged to you, sir. That is all that I wish for.

(*Mr. Bidder.*) I presume, of course, that the Commission will extend the same privilege to me.

(*Chairman.*) Of course.

(*Mr. Beaumont Morice.*) We made an application that the quantities of sewage discharged by the Metropolitan Board from their outfalls should be given to us. We have written for them, but we have not been able to obtain them.

(*Mr. Bidder.*) My learned friend can get them in the proceedings of the last arbitration, of which your secretary has a copy. All that information will be found in print, given most carefully and exactly.

(*Mr. Lumley Smith.*) If there is any doubt about it, we can refer to the notes. It was distinctly promised us by Sir Joseph Bazalgette. He said that it would take a little time to get out, but that the figures were to be sent to us, and we hope to get them.

(*Mr. Bidder.*) Anything that Sir Joseph Bazalgette has promised I am quite sure he will supply. I am told that the explanation is, that it was asked to be furnished on the 12th of December, and it was promised that it should be ready then.

Adjourned to to-morrow at half-past 12 o'clock.

---

# NINTH DAY

## Wednesday 29th November 1882.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ. F.R.S.E. Mem. Inst. C.E.

W. POLE, ESQ., F.RS., *Secretary.*

(*Chairman.*) There is one little correction that I would wish to make with respect to what I stated yesterday about your calling further witnesses, Mr. Morice. If we should desire to hear any further evidence of that kind you will give us the names of any persons who you think can throw light upon this case, and we will examine them ourselves.

(*Mr. Beaumont Morice.*) If you please. There would be no limit as to any number, I suppose. Of course if the Commission give an intimation to that effect, I shall be able to call a good many more witnesses.

(*Chairman.*) Fifty witnesses have told us certain facts, and we might get 500 more to say that they concur in the views laid before us by those 50.

(*Mr. Beaumont Morice.*) I will bear that in mind.

(*Mr. Lumley Smith.*) I appear with my learned friends Mr. Webster and Mr. Balfour Browne for the Corporation of the City of London; and the first gentleman that I propose to tender to the Commission is a gentleman who would to some extent give similar evidence to what has been given before, that is to say, general evidence. But he is a gentleman of a totally different class to those you have heard. He is the vicar of St. Nicholas, Plumstead, and he has taken a good deal of interest in this matter, and seen what he considers to be the effect in his parish; and he is a witness whom the Commission would probably like to hear. With your permission, sir, I will put him in the chair.

The REV. JOHN MCALLISTER called in; examined by Mr. LUMLEY SMITH.

*Rev. J. McAllister.*
29 Nov. 1882.

4785. I believe you are the vicar of St. Nicholas, Plumstead?—Yes. St. Nicholas, Plumstead, is the east end of Plumstead, containing a population of about 15,000.

4786. And you reside at Heathfield, on Plumstead Common?—I do.

4787. How many years have you resided in that parish?—Nineteen years.

4788. Could you point out to the Commission on the map where Plumstead is?—Plumstead is between Woolwich and Erith (*pointing it out*).

4789. And it is to a certain extent off the river?—Yes.

4790. Does the parish go down to the river?—Yes, the north boundary of the parish is the river.

4791. To what extent does it border the river?—About 2 miles.

4792. About 2 miles of the parish is co-terminous with the river?—Yes.

4793. Do your pursuits take you much to the river; do you go on the river?—I am in the habit of going on the river frequently, and by the river.

4794. I believe that you have paid some attention to this question of how far the Thames has been affected by sewage?—As an amateur I have.

4795. Have you on occasions noticed sewage in the river?—Yes, frequently.

4796. Of what parts of the river are you now speaking; are you speaking of the part co-terminous with your parish?—More especially co-terminous with the parish; but in going up and down the river I have seen sewage both above and below.

4797. Has it been going up or going down, or stationary?—Sometimes going up, and sometimes going down.

4798. Your parish is above the outfalls, I understand?—It lies between the mouths of the two outfalls.

4799. When sewage has been going up, I presume the tide must have been flowing up?—Yes, it has been carried up by the tide. I noticed that.

4800. Has that been a matter of frequent occurrence or an exceptional matter, that you have seen sewage going up the river?—I have seen it frequently going

up the river. I could not say that it is an exceptional kind of thing; and sometimes at a time when I should have expected it to have been going the other way.

4801. What do you mean by saying that you have seen it at a time when you would have expected it to have been going the other way?—I always understood that the rule was only to open the sluices at the time when the tide was flowing towards the sea; but I have noticed the sewage floating up t such a time as the sluices must have been shut.

4802. At any rate it was floating up. Have you seen deposits on the sides of the banks?—Yes, frequently.

4803. Have you examined the deposit to see what it was?—I have carefully.

4804. What have you found?—A mass of worms.

4805. What is the character of the deposit?—Evidently human excrement in a state of decomposition.

4806. And breeding living creatures?—Full of them.

4807. Has this deposit any smell?—Yes, a very offensive smell, particularly in the summer season of the year.

4808. Passing from the smell of the mud when you examined it, have you in Plumstead experienced any smell which you attribute to the sewage?—Yes, very often.

4809. (*Chairman.*) Where have you experienced this smell?—All over the parish, a distance of 3 or 4 miles from the river it is very offensive indeed.

4810. (*Sir John Coode.*) Do you think you could discriminate this as being the smell of sewage, at a distance of 3 or 4 miles?—Most easily.

4811. You know that it is not from any of the chemical factories?—I can distinguish the smell from the chemical factories from the other smell as easily as I can the smell of an onion from the smell of boiled cabbage.

4812. And you think that you can detect the sewage smell at a distance of 3 miles from the river, is that so?—Certainly.

4813. (*Mr. Lumley Smith.*) I am afraid you have a good many bad smells in the neighbourhood, but this is perceptibly distinct from the other smells?—Yes, quite distinct.

4814. At what seasons do you find this smell most?—The seasons when we feel it most are the seasons when the north-east wind blows, about the month of March; from the middle of March on to the middle of April, in the early part of the year; then in the autumn from about the middle of September to the end of October. Those are the worst seasons, arising in a measure from the fact that the north-east wind is more prevalent then than at any other time.

4815. Is this smell sufficiently strong to be disagreeable?—It is very disagreeable indeed

4816. Is it a strong smell or a weak smell?—Very strong indeed.

4817. I suppose you visit a good deal amongst all the inhabitants of your parish. I am not treating you as a medical man, but do you find that the health of your parish has been affected at all by the sewage?—I have taken particular interest in noting that, and at certain seasons when these foul odours came over the parish I have noticed that the effect produced upon the health of the inhabitants is much the same as the effect that a hot wind would have on vegetable life if it were blown over vegetable life under certain conditions; that is to say, that the *vis vitæ* sinks directly; and you find that the inhabitants, as a rule, myself included, feel it. I am as healthy a man perhaps as you would find anywhere, but I feel it as others do; that the vitality is not as powerful in the animal system as it is at other times; and I have spoken to some very intelligent medical men about it.

(*Mr. Bidder.*) We must not have what they said.

4818. (*Chairman.*) Within your own personal experience, you have felt that your vitality is not as powerful when under the influence of these smells, as it is at other times?—Yes.

4819. (*Mr. Lumley Smith.*) My learned friend desires that you should not tell us what the views of the medical men were; but however, that is your opinion about it?—Certainly.

4820. Does the effect amount to actual disease, or merely to this diminution of the *vis vitæ* which you have spoken of?—That is a question that I should not like to speak positively upon. During the 19 years that I have been at Plumstead I have had scarlet fever in my own family three times, and I have lost two of my children by it, and, of course, I have my own opinion as to the cause of it; but as I have not been able to trace it positively and distinctly, I should object to commit myself to any positive opinion upon the subject; I mean as to this sewage being the direct cause of disease.

4821. But as to the influence on the vitality of your parishioners, you have an opinion, and that is the opinion you have given us; is that so?—Quite so.

Cross-examined by Mr. Michael.

4822. Could you tell me precisely any dates when you have noticed the sewage floating up?—No, I could not give you any dates; I have not taken any particular notice of that; it has occurred so frequently.

4823. Would you tell me the last time that you saw it?—Last summer.

4824. What part of the summer?—In the months of June and July.

4825. Where were you at that time?—On the river and by the river

4826. On the river itself?—Yes.

4827. What was it that you noticed? What was it that to your mind precised that it was sewage that you saw floating?—I saw black greasy matter, conveying to one's mind much the same impression as if you poured a small stream of ketchup into a basin of ordinary brown soup, having much the same effect upon the water as the ketchup would have upon the soup.

4828. Then you saw ketchup and water, or something of that colour, floating upwards; is that what I am to understand?—Sometimes floating up and sometimes floating down.

4829. Were you able to trace where it came from? How far did you see it come?—I cannot say how far.

4830. Where were you situated?—I have been on the banks of the river at times.

4831. But would you kindly tell me where, because I understand that your parish is partly between the two outfalls; were you standing between the two outfalls when you saw this?—Yes.

4832. At what time of the tide was it?—Sometimes when the tide was coming up I have seen it come, and I suspected at the time that it was let out through the sluices at a time when it should not have been let out.

4833. But did you see that, or was it merely some impression that was conveyed to you?—No, I have seen the sluices opened more than once, but not on that occasion.

4834. Have you seen the sewage from the outfalls going into the Thames?—Yes, frequently.

4835. Have you ever seen it on a flood tide?—Yes.

4836. Could you tell me when? Did you take any note of that?—No, I did not.

4837. Had you been watching it with a view of giving evidence, or was it merely that, being interested in the district, you looked at it from time to time?—I have not been watching it with a view of giving evidence. I had no idea that I was likely to be

*Rev. J. McAllister.*

29 Nov. 1882.

called to give evidence on the subject until a few days ago.

4838. Was it for pleasure that you went on the river?—Sometimes I go up and down the river for pleasure, sometimes to visit friends who are living further down or further up.

4839. Did you ever go specially for the purpose of taking observations?—Never.

4840. You merely noticed casually when you were there?—Casually.

4841. Within what periods have you noticed these large deposits of worms that you speak of?—Every summer for the last 9 or 10 years.

4842. Were there any before 9 or 10 years ago on this particular spot?—My attention was not particularly directed to that.

4843. Do you consider the presence of these worms an evidence of the presence of sewage?—A certain kind of worm I should think was.

4844. I do not ask scientifically what is the kind, but what is the appearance of these worms?—Small red worms.

4845. But when you say that they are small, could you tell me how long they are; are they a millimetre in length?—Some of them are two or three inches long, and some are very small.

4846. Were they in large quantities?—Yes, in very large quantities.

4847. A mass of them?—Yes.

4848. And from that you gathered the impression that this was sewage matter in which these worms had either bred or accumulated?—Certainly not. I should not infer from seeing a mass of worms that it was sewage at all. I infer that it was sewage from the smell of it.

4849. Could you tell me when you first saw these worms?—I could not.

4850. Can you tell me when you first examined the sewage which you say was deposited on the side of the river?—I have been examining it, as I told you just now, for the last 8 or 10 years.

4851. Microscopically?—No.

4852. Do you remember that part of the river before the outfalls were established?—No, I do not.

4853. Have you made any investigation otherwise than by taking some of the mud, and looking at it?—No, not by any analysis.

4854. Physically, or chemically, or microscopically?—No.

4855. In what respect does it differ from the mud that is to be found in other parts of the river?—The mud that is to be found in other parts of the river does not emit a smell of an offensive kind, a smell almost always, I think, as far as my knowledge goes, inseparable from sewage in a certain state of decomposition.

4856. Have you ever had an opportunity of examining the mud taken out of a small pond in a gentleman's park, and of observing the smell arising simply from the decaying vegetable matter; have you ever taken it in your hand?—No, I cannot say that I have taken it in my hand; I have smelt it.

4857. Was that very agreeable?—It was not agreeable, certainly, but it was a different smell.

4858. So that you think that you could discriminate at once (I do not put it offensively, but, as you say, you have not examined it scientifically) if two different samples were put before you, so as to be able to say, "This is Thames sewage matter and this is "vegetable matter from a pond"?—I think I could if the mud from the Thames were the mud to which I refer; that is to say, deposit of the heavier part of the sewage.

4859–60. I want you to answer me two questions. I am going to ask you first to tell me precisely the spot where you took the sewage mud; and then to tell me afterwards some spot upon the River Thames where you have taken the ordinary mud of the river with which you have compared it.

(*Chairman.*) I did not understand the witness to say that he had taken samples of the ordinary mud.

(*Witness.*) I did not say so.

(*Mr. Michael.*) He says that it differs from ordinary Thames mud.

(*Chairman.*) You must not assume a fact even in cross-examination. He has not said that he did take any ordinary mud.

(*Mr. Michael.*) I speak with great deference, of course, sir, to your great experience; but if the gentleman says that it differs from ordinary Thames mud, he must have had Thames mud in order to compare it, or else how could he point out the difference?

(*Chairman.*) He does not say that he ever took a sample.

4861. (*Mr. Michael.*) Taking a sample is merely taking a bit. (*To the witness.*) I may have used rather a roundabout expression. Where did you see the mud that you say is contaminated with sewage?—I should like to say that there are certain places in little creeks where there is an eddy of water which carries in the heavier part of the sewage, and it is deposited there. There are other parts, more open parts, where, so far as my knowledge goes, this sewage does not lodge to the same extent, and where you will find the ordinary kind of mud.

4862. All that may be perfectly true, but I wish the Commission to know where is the particular spot where you saw mud deposited which you consider to be sewage mud?—You ask me a question that is very hard to answer. I cannot point out a certain particular spot. I have gone along the banks of the river; there was no particular spot. At such a place as I found mud of that character I would examine it and smell it.

4863. Where are the spots at which you have seen that kind of mud?—There are certain spots lying between the outfall at Crossness and the boundary of the Royal Arsenal at Woolwich.

4864. And those are the spots where you say you have seen sewage mud deposited?—Yes, in some places.

4865. Where is the other part where you have seen mud which you say differs from that on the shore of the Thames?—In the more open parts along the same shore.

4866. That is sufficient for me. Along the more open parts the mud is entirely different. I do not want to ask you any painful question about this scarlet fever in your family, but just a word about this diminution of *vis vitæ*. Yours is a very marshy district, is it not?—No; where I live is a very healthy district, up on the common.

4867. But is it not the fact that your parish is a large tract of alluvial deposit, and very marshy?—No, it is not the fact. Part of it includes the government range, which is a marsh, and part of it is high ground, Plumstead Common for example, which is a rising ground stretching from the marshes.

4868. You said no, and then you at once qualify the no by saying yes, a large portion of your district is marshy?—I should like to be clear on this matter. You ask me a general question whether my parish is not a parish consisting of marshes, and I answer that it is not so. Part of it is marshy land, but more than half of it is high land.

4869. Then half of it is marshy and half is not; shall we put it in that way? At any rate, is a portion of your district of a marshy character?—It is.

4870. When the north-east wind blows over it does it blow over the marshes from the river to the other parts of your parish?—Yes.

4871. You are a gentleman of experience and seem to have thought this matter out, as you talk of *vis vitæ*, what is the general influence of the north-east wind upon the health of a population when that wind blows over marsh land, putting sewage out of the question?—I apprehend that it would depend upon the character of the marshes. If there was a great deal of sour half-decomposed water lying in the marshes, I apprehend that it would be injurious; but

if the marshes were only flat lands and well drained I take it that the effect would not be injurious.

4872. Are your flat lands well drained?—They are supposed to be well drained.

4873. There is nothing of an injurious character in your opinion that could emanate from those marshes?—I do not know.

4874. Do any cases of ague occur in your district?—I have never known a case of ague in the parish since I came to it.

4875. Do you look from week to week at the returns made by the Poor Law medical officer of your district?—I am a member of the board of guardians.

4876. That is not an answer to my question. So you may be, and yet you may never have seen the returns. Do you look at the returns of your Poor Law medical officer?—I do.

4877. And you are able to say that no case of ague has occurred there?—I have never known a single case of real ague.

4878. What is the general health of the district as compared with that of the whole of the metropolis?—Not so good as some, perhaps as good as others.

4879. What is the general mortality per 1000 per annum?—I could not tell that.

4880. But you look every week?—Yes.

(*Chairman.*) Shall we not get that evidence very much better by the returns?

(*Mr. Michael.*) I do not know that they will be here. I have not got them, though I happen to know them. This gentleman is a member of the board of guardians, and he says that he looks at the returns; therefore, I think I am in order in asking him these questions, though I bow with great deference to your decision if you wish to stop me.

(*Chairman.*) I do not say that you are not in order; I only say that the best evidence would be the returns themselves.

4881. (*Mr. Michael to the witness.*) You do not know the rate of mortality in your district?—I know it from time to time by seeing it.

4882. (*Chairman.*) Can you charge your memory with it?—The general impression on my mind is that we stand lower than most of the other districts, and about equal to some of the worst of them.

4883. But you cannot tell us what is the rate of mortality?—I cannot.

4884. (*Mr. Michael.*) Could you tell me supposing that the mortality were 20 per 1,000 in your district, how much of that is attributable to preventible diseases, zymotic diseases?—It is a difficult question for me to answer.

4885. How much is attributable to scarlet fever, do you know that?—Scarlet fever we never get rid of.

4886. And you attribute that to the state of the Thames, do you?—Not altogether. I attribute the violent periodical outbreaks which we have had at certain seasons of the year very much to the poisoning of the atmosphere.

4887. Do the board of guardians take any special means of isolating these cases and preventing the spread of the disease?—We do all we can so to do, but it is a very difficult matter.

4888. Has your medical officer reported to you upon the means to be taken in order to avoid the incidence of these epidemics of scarlet fever?—I do not know that he has made any special report.

4889. Have you had specially brought to your notice the desirability of abolishing cesspools in the district?—That has been done long ago. We have the main drainage in our parish.

4890. But have you discontinued all cesspools?—They are supposed to be discontinued. Wherever the main drainage comes within reach of the houses or streets they are supposed to be drained and connected.

4891. Has the medical officer reported to you specially on wells in connexion with cesspools, and on the pollution of the water from contact with cesspools, or in the vicinity of cesspools?—No.

4892. Neither the medical officer of health, nor the medical officer of the Poor Law?—We have no medical officer of health; they have a local board of health in Woolwich, but not in Plumstead.

4893. But there is a medical officer of health. However, if you do not know it, I will pass that over. Now does typhoid fever prevail in your district?—We have not very many cases, but we have some.

4894. Do you know how many deaths from scarlet fever occurred in your district during last year, 1881?—I could not tell, but there were a great many.

4895. You have given one answer of a very extraordinary character, if you will allow me to say so, when you say that you can detect three or four miles away the sewage smell from the Thames, and that you are able to distinguish that smell from the factory and other smells?—Quite so.

4896. Have you upon the Thames itself during the month that you have given us, that is to say, if I rightly appreciated your answer, in March and April, smelt a smell given off by the sewage in the Thames?—Do you mean last March, or any particular March.

4897. I understood you to say that the two great periods of the year in which the smell of the sewage is distinguishable are March and April, and also September and October; am I right in saying that?—Yes.

4898. Have you in March and April in any year smelt on the Thames itself the smell of sewage which you allege to be prevalent in your district?—Yes.

4899. And do you say that that extends for a distance of three or four miles?—Yes. It depends upon the state of the atmosphere and upon the state of the wind.

4900. Do you know the outfalls of sewage that are still undealt with on the sides of the Thames?—I do not understand your question.

4901. There are two great systems of sewerage in the metropolis, one of which takes the whole of the north of London and the other takes the whole of the south?—Yes.

4902. I daresay you are aware that there are a great number of outfalls still undealt with at Erith and at various other places where sewage discharges itself on the bank of the Thames; do you know that?—I was not aware that there was any place of any magnitude.

(*Chairman.*) Do you mean upon the Plumstead bank?

(*Mr. Michael.*) I am not putting it specifically. This gentleman says that he goes up and down, and I am putting Erith as an instance.

(*Mr. Abernethy.*) You are taking him a long way down the river if you take him down to Erith.

4903. (*Mr. Michael.*) I will ask him about this one, which is in his own district. (*To the witness.*) Do you know the gasworks at Beckton?—I do, very well.

4904. Have you seen the matter that discharges tself from the gasworks at Beckton?—I have.

4905. Have seen the sewage which comes down Barking Creek?—Yes, I have.

4906. Have you smelt it?—Yes.

4907. Does that in any way differ from the smell which you have spoken of; is it fainter or stronger from Barking Creek?—I could not say; it depends so much upon the state of the atmosphere and upon the state of the wind.

4908. Is that the smell which you have noticed in March and April three miles of?

(*Mr. Lumley Smith.*) There is a little confusion I think between Barking Creek and Barking outfall.

4909. (*Mr. Michael.*) I am not mentioning the outfall at Barking, but there is a creek where a very large quantity of sewage discharges itself entirely independent of the Metropolitan Board of Works. (*To the witness.*) You know that, do you not?—Yes.

4910. Have you smelt that that is extremely offensive?—I have never perceived that.

4911. How near have you been to Barking Creek?—Close to it, and on it, and round it, and all about it.

*Rev. J. McAllister.*

29 Nov. 1882.

4912. And you have never been able to distinguish any bad smell either from the banks of Barking Creek or from the water coming down the creek itself?—No, not any particular smell.

4913. You have been close to Barking Creek?—Yes.

4914. And you have seen the spit of land that comes out, and the banks on both sides of the creek and the water coming down?—Yes.

4915. And you have never distinguished anything bad at any time of the year there?—No. I should tell you, in order to be candid with you, that my attention was not particularly directed to making any investigation in that particular place.

4916. But, however, you have not detected any bad smell there?—No, I have not.

4917. Now will you kindly tell me with respect to the other period of the year which you mentioned, namely, in September and October, whether you have detected the same smell of sewage three or four miles in the interior of the country?—I have.

4918. In September and October of this year?—Not so much this year. I have observed that.

4919. And those are the only periods at which this smell is distinguishable?—They are not the only periods, but the worst ones. It depends, as I have already stated, so much upon the wind. When the wind blows in a certain direction, then we get it.

4920. When the wind is from the north-east it blows over the river, and it forces the sewage smell three or four miles into the interior?—Yes.

4921. And that you have noticed every year?—Yes, I have.

4922. Has your attention, as being interested in the public health of the district, ever been directed to the nuisances evolved from the factories on either side of the river?—Yes.

4923. Have you joined with any other boards in striving to mitigate the nuisance arising from those factories?—No.

4924. Have you ever made complaints upon the subject?—Yes, frequently.

4925. Have the board of guardians taken any steps in the matter?—No particular steps.

4926. Have you employed anyone to make a report upon the factories?—No.

4927. Did your medical officer join in making any report, or did he report it to you?—No.

4928. To what public body did you complain when you made a complaint of the factories?—We have not complained to any public body—we have complained bitterly of the nuisances there; but the general impression on the minds of every one to whom I have spoken was this; what is the good of trying to remedy this when the other nuisance of the Thames is so great? You must deal with it as a whole.

4929. Have the guardians passed any resolution with respect to these nuisances?—No.

4930. Or with respect to any nuisances at all?—No.

4931. Have they ever taken any active steps as a board of guardians?—No.

Examined by the COMMISSION.

4932. (*Dr. de Chaumont.*) With regard to the depression of *vis vitæ* that you speak of, have you observed any difference in that during the long time that you have been in Plumstead?—Yes, I have noticed it, as far as one could measure it, it is not the kind of thing that you could measure exactly; but I certainly have noticed that at certain seasons of the year when patients, in whom I am particularly interested, complain of this kind of thing and when I take them to a medical man, his pharmacopœia consists almost entirely of quinine.

4933. Is that more the case than it used to be?—Yes.

4934. Have you yourself felt the effects of this depression?—Yes.

4935. And you think you feel it more now than you did?—I do. Perhaps that is not a safe guide because I am not quite so young as I used to be.

4936. But you think it has been increasing?—I do.

4937. You have no local board of health, have you?—There is a local board of health at Woolwich, but not at Plumstead.

4938. Then the board of guardians is the sanitary authority?—Yes.

4939. But you have a medical officer of health?—Perhaps I am misleading you. The board of guardians is not altogether the sanitary authority, but there is the Plumstead Board of Works which takes cognizance of sanitary matters.

4940. Then are you directly under that board of works for sanitary purposes? When nuisances take place do the complaints go to the board of works?—There are certain sanitary things which come under the cognizance of the district board of works, and certain others which come under the cognizance of the board of guardians; but of course, anything connected with the sewage would be referred to the board of works.

4941. But you have a medical officer of the district?—Yes.

(*Mr. Michael.*) There must be a district board of works at Plumstead, and the district board of works is the sanitary authority for the district, and they are obliged to have a medical officer of health.

4942. (*Chairman to the witness.*) How far is your house from the railway, in a straight line?—About half a mile.

4942*a*. The Plumstead marshes begin just about the railway, do they not?—Yes, that is to say, they extend from the railway towards the river, and then the higher ground slopes up towards Plumstead Common.

4943. Then your house is within half a mile of what are called the Plumstead Marshes?—Yes.

4944. (*Dr. Stevenson.*) Do you know Silvertown and that district?—Yes.

4945. That will be within three miles of your house, I suppose?—As the crow flies, I should think it would.

4946. Are there any chemical factories there that you know have been complained of?—I have not heard of any complaints.

4947. You know that there are chemical factories there, where they distil tar and make chloride of lime?—Yes.

4948. You have not heard them complained of?—No.

4949. Have the inhabitants of your district, or of any of the districts in the neighbourhood, complained of these works generally, about Silvertown?—No.

(*Mr. Michael.*) It is two-and-a-half miles; we have measured it.

4950. (*Chairman to the witness.*) You mentioned that you had smelt that peculiarly offensive smell three or four miles away from the river—do you recollect at what place you were when you smelt it?—Yes, at East Wickham; I have frequently smelt it when I have been at the residence of Mr. Jones, who lives at East Wickham House.

4951. Is that the most distant point at which you have smelt it?—Yes. That is more than three miles from the outfall.

4952. (*Sir John Coode.*) You told us that there were some occasions on which you yourself had seen the outfall sluices actually opened?—Yes.

4953. About how many times have you seen that yourself?—Perhaps a dozen times.

4954. Did you take a note of the state of the tide on those occasions, whether the tide was ebbing or flowing, or how?—Yes; I have noticed more than once that the tide appeared to me to be coming up instead of going down.

4955. You did not know the time of high water, because the tide may flow along the shore before high

water?—Of course, I do not like to speak very positively upon that matter: but I merely tell you the impression that was made upon my mind at the time when I saw the sewage floating up.

4956. My question refers to the time at which you yourself saw the outfall sluices opened, and you say that on several occasions you saw them opened at a time when the current was running up stream?—Yes.

4957. (*Colonel Ewart.*) You have told us the nature of your means of disposing of the sewage; but I do not think you have told us what is the nature of the water supply generally in your parish; is it from wells or from waterworks?—Artesian wells. The North Kent Waterworks supply the water and it is said to be the best water in the neighbourhood of London.

4958. (*Chairman.*) Is your house supplied by the waterworks?—Yes.

4959. And was it so at the time when you had these unfortunate attacks of scarlet fever?—It was.

4960. (*Sir John Coode.*) And is the surrounding district generally supplied by the same waterworks?—I believe the whole district is supplied from the Kent Waterworks.

4961. (*Colonel Ewart.*) As regards these marshes that you speak of, can you say from your general observation whether there is much stagnant matter there, or are they relieved by a system of drainage?—They are relieved by a system of drainage; there is a perfect system of drainage. The Government, I think, look to their own part of it, that part of the marshes which is covered by the Government range; and then there are arrangements made for draining the other part and draining it perfectly by means of sluices which are opened at certain times.

The witness withdrew.

Mr. Henry Passfield called in; examined by Mr. Balfour Browne.

4962. Where do you live?—At Lambeth.

4963. What are you by trade?—A fisherman.

4964. What is your age?—Forty-five.

4965. How long have you fished in the river?—Over 30 years.

4966. What parts of the river do you principally fish in?—Up the country in the first part of the year, up to about August.

4967. Do you fish down the river at all?—Yes.

4968. What do you mean by "up the river," above this place where we are now?—Yes, up from about Chiswick, in all parts.

4969. (*Chairman.*) Do you go from this to Chiswick or do you go above Chiswick?—I have been to Sunbury.

4970. How far up the country are you in the habit of fishing?—Say from Sunbury down.

4971. (*Mr. Bidder.*) Down to where?—I have been down to Hungerford.

4972. (*Chairman.*) You are in the habit of fishing between Hungerford and Sunbury?—Yes.

4973. (*Mr. Balfour Browne.*) Do you ever fish below Hungerford, further down the river more towards the sea?—Yes.

4974. How low down do you fish?—Down as far as the Lower Hope Point I have been.

4975. Does it depend upon the time of the year whether you are fishing up the river or down the river?—Yes.

4976. Can you notice any change in the river in recent years?—Yes.

(*Mr. Bidder.*) Is not this the very thing that was admitted?

(*Mr. Balfour Browne.*) It is not the same thing.

4977. (*Chairman to the witness.*) What change have you noticed in the river in recent years?—About five or six years after the sewage came into the river from the outfalls at Barking and Halfway Point, it took an effect upon the river.

4978. How did it affect the river then?—We could not catch the fish there.

4979. (*Mr. Balfour Browne.*) What fish were you in the habit of fishing for?—Shrimps.

4980. Did you ever fish for flounders?—No; I never followed flounder catching.

4981. Was it only the shrimp that you went about?—What I fished after for my living was eels.

4982. Do you know Limehouse Reach?—Yes.

4983. Are there any fish to be caught in Limehouse Reach now?—No; I have known them to catch a few for one day or so, but I have never caught any there myself.

4984. Limehouse Reach is above the outfalls, is it not?—Yes, a few miles above.

4985. Are the fish, according to your view, driven away from Limehouse Reach in consequence of the sewage?—No; I have never worked from there.

(*Mr. Bidder.*) I must object to that as a leading question.

(*Chairman.*) The value of the evidence is of the very slightest description.

4986. (*Mr. Balfour Browne to the witness.*) Can you tell the Commission whether flounders, dace, roach, and eels can be caught in the river at Hungerford Bridge?—Yes, at certain times of the year.

4987. At what time of the year can they be caught at Hungerford Bridge?—About August and September.

4988. Can they be caught any lower down the river?—No; not without you go right down below Gravesend.

4989. Can you tell the Commission at what point they can again be caught going down the river?—Yes, down below Gravesend.

4990. So that, although at certain seasons of the year, you can catch these fish at Hungerford Bridge, you cannot catch them between Hungerford Bridge and below Gravesend?—That is so.

Cross-examined by Mr. Bidder.

4991. Do you catch roach and dace down at Gravesend?—No.

4992. But you do catch roach and dace down by Hungerford Bridge?—Yes.

4993. My learned friend asked you if you also caught them below, and you said that you caught them down below Gravesend?—No; roach and dace are fresh-water fish, and the lowest that they reach is down to here according to the tides.

4994. They never go into the salt water?—No.

4995. Therefore, it is a mistake to say that they are caught below Gravesend; eels of course may be caught below Gravesend?—Yes; eels are salt-water fish as well as fresh-water fish.

4996. And shrimps and flounders?—Yes, and whitebait.

4997. Eels you catch both up the river and down the river, do you?—Yes.

4998. I daresay you can tell me something about the eels; they go down to the sea at certain times of the year, do they not?—No, these eels that you catch up this way are of a different class.

Examined by the Commission.

4999. (*Chairman.*) You said that you fished down from Hungerford to Gravesend; is that so?—No.

5000. (*Mr. Balfour Browne.*) Will you explain how that is?—When you are going down for salt water fishing, you have to put different gear in the boat; and if you are fishing up the river this week, say, you put the other gear in the boat, and then if you want to shift down to below Gravesend you put the salt water gear in the boat.

5001. (*Sir John Coode.*) Do you ever try to catch fish between Hungerford and Gravesend?—No.

*Mr. H. Passfield.*

29 Nov. 1882.

5002. Why not?—Because we cannot do so now on account of the sewage. We used to work for eels in Halfway Reach, Barking, Greenhithe, Erith, and Long Reach, and we never used to think of going further.

5003. Are there or are there not fish between Hungerford and Gravesend?—No; nothing will live there in warm weather.

5004. That is the reason?—Yes.

5005. You are sure of that?—Yes.

5006. You have tried it?—Yes.

5007. For how long has that been the case?—Five or six years after the sewerage had been started we could not catch any eels at Erith; and then every year it got worse by degrees. Then we had to work at Greenhithe.

5008. Then you mean to tell us that the fish have disappeared now between Hungerford Bridge and Gravesend?—Yes.

The witness withdrew.

(*Mr. Bidder.*) As I said many meetings ago, I say again now, that there is no doubt that the fish have so far disappeared in that middle reach of the river that it is not worth a man's while to fish there now.

(*Chairman.*) Then we need not have any cross-examination upon that point.

Mr. WILLIAM HENRY LEWIS called in; examined by Mr. LUMLEY SMITH.

*Mr. W. H. Lewis.*

5009. I believe you reside at King William Street, Greenwich?—Yes.

5010. And I believe you are the Port Sanitary Inspector?—Yes, under the Corporation, the Port of London sanitary authority.

5011. What is the extent of your district?—The extent of the jurisdiction of the sanitary authority is from Teddington Lock down to the north-east corner of the Isle of Grain.

5011*a*. (*Sir John Coode.*) Have you charge of the whole of that district?—That is the jurisdiction of the sanitary authority.

5011*b*. (*Mr. Lumley Smith.*) Are there more inspectors than yourself?—Yes, there are two others.

5012. Have you any particular part of the river to attend to, or do you go over the whole?—I am chiefly engaged between Greenhithe or Erith, and, say, up as far as Battersea. That is my usual work. There are times, of course, when I am down at the two ends; that is to say, at the higher and the lower end.

5013. But you are specially conversant with the part of the river that you have told us of?—Yes.

5014. How many years have you been in that capacity?—Since 1873; the date of the formation of the authority.

5015. Does your duty take you constantly on to the river?—Yes, in some portion of it.

5016. Every day, or how often?—Every day.

5017. Have you noticed in the course of the time which has elapsed between 1873 and the present time, any change in the character of the river?—A most decided change.

5018. Will you tell the Commission shortly what the change has been?—Take, for instance, the year 1880. The river then was very black indeed during the summer, say from Jenningtree Point right up pretty well to the Cherry Garden Pier. That was in July 1880.

5019. That was a very bad time?—Very bad indeed.

5020. Bad in what respect?—It was in black patches; it seemed like floating mud, as it were, in black stinking matter. As soon as you touched it it tumbled to pieces. This black floating stuff on the water seemed as if it came from the bottom, as though it had been drawn up by the heat.

5021. It seemed to have come up in patches from the bottom, and then it floated on the top?—That is so.

5022. Did it break up then, or did it break when it was touched?—It broke up at the slightest touch.

5023. But the patches might be the size of a table, or they might be the size of a room; what was their size?—They were all kinds of shapes; the large ones would be about six to eight feet in length, and the small ones would be about half that; and their breadth would vary from three feet to six feet, speaking roughly.

5024. Did that have the appearance at all of common Thames mud?—Oh, no, not at all.

5025. Was there anything else about it; was it offensive in any way?—Very offensive.

5026. In what way?—There was a fearful stench with it.

5027. This you say was in July 1880; did that last for any considerable time in 1880?—It lasted nearly the whole of the month of July, up to the early part of August, and then it came on to rain, and there was a thunderstorm, and down went this thick stuff, and it did not appear again during the wet season after the rain came.

5028. (*Chairman.*) Never again?—Not then.

5029. (*Mr. Lumley Smith.*) Had that occurred before within your knowledge?—In 1858.

5030. You have known the river for a long time, I presume?—At that time I was connected with the Dreadnought Seamen's Hospital.

5031. Where was that moored?—It was moored off Greenwich.

5032. In 1858 do you remember anything similar to what you saw in 1880?—There was a greater amount, and it lasted for a longer time.

5033. (*Mr. Bidder.*) Was it worse?—Yes, because these patches extended the whole width of the river; in fact then it was a black ditch.

5034. The same sort of thing as occurred in 1880, but much worse?—Much worse.

5035. (*Sir John Coode.*) Was it in the same part of the river?—No. In 1858 it was in the part from Greenwich up to London.

5036. (*Mr. Lumley Smith.*) It was a bad time then in London?—Yes.

5037. That was of course before the Metropolitan drainage was in force?—Yes.

5038. At that time you saw something similar between Greenwich and London?—Yes.

(*Mr. Bidder.*) Much worse.

5039. (*Mr. Lumley Smith.*) Was it in patches?—No; it was one full black ditch.

5040. (*Mr. Abernethy.*) In what part of the river did you see the patches that you spoke of first, and which you saw in July 1880?—Say from Jenningtree Point up to near Cherry Garden Pier.

5041. (*Mr. Lumley Smith.*) In July 1880 these patches did not pervade the Thames for the whole of the year; but in other parts of the year have you noticed anything in the river at all; has there been any change in the character of the river?—Yes; after, say 1864, the river seemed very good; and during these last six or eight years, speaking roughly, the river has assumed rather a bad character; it has been getting gradually worse than it was prior to that time.

5042. (*Chairman.*) What do you mean by getting worse?—Take the northern outfall or the southern outfall: the river there assumes a very black appearance and smells very badly.

5043. Then what you mean by its getting worse, is that it is getting blacker and smells worse?—Yes.

5044. (*Sir John Coode.*) Within the last six or eight years?—Yes.

5045. (*Mr. Lumley Smith.*) Has there been any recurrence of this appearance of the patches since July 1880?—At times there has been a little. I think that in July this year it began to be rather bad.

5046. (*Mr. Bidder.*) But not so bad as it was in 1880?—No.

5047. (*Mr. Lumley Smith.*) Have you noticed sewage in the river?—Oh, yes.

5048. Have you ever noticed it coming up stream?—Yes; that is a thing that you can see very frequently at Barking.

5049. I will come to some observations that you took a little later; but you have seen it coming up stream at Barking; how far up the river have you seen it from Barking?—There have been times when I have traced it,—I could not say whether it came from Barking or from Crossness,—but I have traced it up to the lower part of Blackwall Reach.

5050. (*Sir John Coode.*) When was that?—At different times.

5051. More than once?—Yes, frequently.

5052. (*Mr. Lumley Smith.*) When you say that you traced it, were you able to trace it as having come from Barking or from Crossness, or may it have come from some outfall on the other side, or elsewhere?—You could see it from either one place or the other, either Barking or Crossness.

5053. There is a distinct track?—Yes, quite so. You might lose the track for about half a dozen feet or half a dozen yards; but you can see a distinct track from Barking or Crossness.

5054. You are not speaking of Barking Creek?—No, of the Barking outfall.

5055. You say that you may lose it for a few feet, but that you come upon it again?—Yes.

5056. You are able to distinguish that this sewage, which you trace up the river Thames, comes from the outfalls?—Yes.

5057. Of course if it is flowing up stream, the tide must be flowing?—Yes.

5058. Did you take any samples of the water in 1880, at that bad time that you are speaking of?—I took some samples once; I was with the medical officer.

5059. Who was that?—Dr. Collingridge.

5060. (*Mr. Bidder.*) Where?—At Jenningtree Point, at Purfleet, by the "Cornwall," and at Charlton inside the "Warspite."

5061. Were the samples taken at high water or at low water?—They were taken on the flood.

5062. (*Sir John Coode.*) At different periods of the flood tide?—In commencing from Jenningtree Point it would allow, you may say, before we got to Charlton, an hour and a half.

5063. (*Mr. Lumley Smith.*) Did you examine it yourself to see what was the nature of the water?—Only by smelling it.

5064. What was the smell like?—A stink.

5065. Did it smell like pure water, or what did it smell like?—Like sewage.

5066. On the 30th of June 1882, that is to say this year, I am told that you were again with Dr. Collingridge?—Yes.

5067. Did you take some samples then?—Yes, there were several samples taken then.

5068. You recollect the occasion?—I do; there were several gentlemen present at the time.

5069. Can you tell us where the samples were taken?—Yes; No. 1 was taken within Barking Creek, a little way up from the mouth, on the ebb.

5070. (*Chairman.*) Was it low water?—No; the tide had fallen, roughly speaking, say twenty minutes.

5071. (*Mr. Bidder.*) About half an hour after high water?—Yes. Then I cannot tell you exactly where No. 2 was taken; but there were several samples taken as far down as Gray's.

(*Sir John Coode.*) It is very material to know where the samples were taken.

(*Mr. Bidder.*) A great deal turns upon this.

(*Mr. Lumley Smith.*) Dr. Collingridge was with him.

5072. (*Chairman to the witness.*) Did you take any note of the places where you took those samples?—Yes, I have them in my daily book.

5073. Then look at your book and refresh your memory. Those are entries made at about the time?—Yes.

5074. Were they made by yourself?—They were made by myself.

5075. Look at those entries and tell us where the first sample was taken?—At Barking Creek, a few yards up the creek, at 2.25. No. 2 was taken close in at Lawes' Chemical Works at Barking at 2.30. No. 3 was taken at Barking in a line with the sewage, about 200 yards below the Barking outfall, the time at which it was taken being 2.35.

5076. (*Sir John Coode.*) What time was it high water that day?—It was high water at London Bridge at 1.9 p.m. No. 4 was taken at Halfway House Point on the south shore off the surface, about 30 feet from the bank, at 2.50. The others were taken at a depth of two or three feet. No. 5 was taken at about 50 yards above the outfall at Crossness.

5077. (*Mr. Lumley Smith.*) Was that off the surface or below?—Below. The time at which it was taken was 2.55.

5078. About how deep did you go to get the samples on those occasions?—About three feet.

5079. I think you have got a sixth sample, have you not?—Yes; that was taken at Crossness over the line of sewage discharging from the outfall; that is in the direct line of the sewage as you trace it down. The time when that sample was taken was 2.59.

5080. Is that taken from the surface?—No.

5081. Unless you tell us it is from the surface, we may assume that it is not?—Yes.

5082. Now, then, going to No. 7, where was that taken?—Off the second jetty at Crossness pumping station, in a line with the shaft, about 120 feet off the quay, at 2.59

5083. (*Mr. Michael.*) There are three jetties at Crossness?—Yes.

5084. (*Mr. Lumley Smith.*) Now, will you give us No. 8?—No. 8 was taken at the West Kent tanks from the upper and middle reservoirs, about half of each, the time being 3.55.

5085. They are all taken, I see, on the same afternoon and within a short time after each other?—Yes.

5086. I think Dr. Collingridge, the medical officer of health, was in the boat with you?—Yes.

5087. Have you any others?—Yes, I have three others. Then sample No. 9 was taken at Greenhithe in a line with the causeway, the time being 5. 40.

5088. What part of the channel was it in?—Close in shore.

5089. What are your other two samples?—No. 10 was taken at Barking, at the sewer at low water, the time being 7.10, and the outfall running with great force.

5090. (*Mr. Bidder.*) In a line with the discharge of the sewage?—This is into the mud.

5091. (*Mr. Lumley Smith.*) Where was No. 11 taken?—No. 11 was taken at Barking at 150 feet below the outfall; that is taken from the bottom.

5092. (*Mr. Bidder.*) How far out from the shore?—Close in shore; the bottle stuck to the bottom. The time at which that sample was taken was 7.15.

5093. (*Mr. Lumley Smith.*) Was the outfall still running then?—Yes.

5094. Dr. Collingridge was in the boat with you, was he not?—Yes, he was.

5095. And I think Dr. Tidy?—Yes.

5096. And Mr. Baldwin Latham, I think?—Yes, and other gentlemen. I do not know their names.

5097. I believe that you also took some observations from midday on the 28th of July to 10 o'clock a.m. on the 29th of July in the present year?—Yes.

5098. And I believe that you carefully watched the times at which the sewers were running?—Yes.

5099. Where were you stationed?—At the Crossness pumping station.

5100. How far from the outfall?—Right at the outfall.

5101. I do not know whether you found it a pleasant night's work?—The stench was awful. I had one night of it. The beauty of it was that Saturday was the next day, and on Sunday we could square ourselves again.

*Mr. W. H. Lewis.*

29 Nov. 1882.

5102. (*Sir John Coode.*) Were you afloat or on shore at this time?—I was in a boat all the night.

5103. (*Mr. Lumley Smith.*) It would be about 60 or 70 feet off the quay, I suppose?—It would be somewhere near that. I was in an open boat sampling the water the whole of the night—in fact, the whole of the day too—for 24 hours; and I sampled this water direct at the outfall. The outfall is situated at the upper portion of that part of the Crossness pumping station, just about one fourth of the quay, just above the jetty, and in a line with the jetty; and I was quite certain of getting at the outfall, for my bottle, which I sampled the water in, caught in this outfall.

5104. In the stream you mean?—Yes.

5105. I believe you have the entries in your book, have you not?—I have.

*The following paper was handed in.*

CROSSNESS PUMPING STATION.

SAMPLE WATER taken from the OUTFALL from MIDDAY 28th July to 10 o'clock July 29th.

28th July, morning. High water, 11.53.
29th July, morning. High water, 12.23.

Wind—Light, changeable.

| No. | Time Sample taken. | Place. | Remarks. |
|---|---|---|---|
| 1 | July 28th, mid-day, 12.0. | Near the upper outfall. | About 60 to 70 feet off the quay near the centre, about three feet below surface. |
| 2 | 1 p.m. | Do. | Near the same place at 1.40. Stinks badly. (Sewer running.) |
| 3 | 2 p.m. | Do. | 18 feet below surface. (Sewer running.) |
| 4 | 3 p.m. | Do. | Do. 17 feet below surface. (Sewer running.) |
| 5 | 4 p.m. | Near this same place, 16 feet below surface. | 3.5 observed the lower outfall running. Water discoloured and warm. 3.0 felt the outfall; supposed wood. |
| 6 | 5 p.m. | Do. 11 feet below, four or five feet from edge of water (or mud). | About 4.0 upper outfall stopped running. (Lower sewer running.) |
| 7 | 6 p.m. | Do. do. | Three to four from water edge. Water warm; smell very bad. (Lower jetty outfall still running.) |
| 8 | 7 p.m. | Do. 16 feet from the mud. | 15 feet below surface. |
| 9 | 8 p.m. | Do. about 70 to 80 feet off quay. | 16 do. do. |
| 10 | 9 p.m. | Do. do. | 16 do. do. foggy. |
| 11 | 10 p.m. | Do. do. | 18 do. do. (10.15 foggy). |
| 12 | 11 p.m. | Do. do. | 18 do. do. (11.20 the upper outfall opened). Stopped, should think, about 3.30; it then seemed to run till 4 o'clock. |
| 13 | 12 midnight | Three or four feet from surface. | All taken near same place. (Sewer running.) |
| 14 | July 29th, 1 a.m. | Do. do. | Do. do. do. |
| 15 | 2 a.m. | From the bottom | The bottle caught in outfall 2.15 before it was cleared, 18 feet below surface. (Sewer running.) |
| 16 | 3 a.m. | Do. do. | 17 feet below surface. (Sewer running.) Stinks. |
| 17 | 4 a.m. | Do. do. | Do. (very foggy). |
| 18 | 5 a.m. | Do. do. | 11 feet below surface. |
| 19 | 6 a.m. | Do. do. | Do. (very foggy). |
| 20 | 7 a.m. | Near the upper outfall. | 10 feet do. (Lower outfall still running). |
| 21 | 8 a.m. | Do. do. | 11 feet below surface. |
| 22 | 9 a.m. | Do. do. | 16 do. do. |
| 23 | 10 a.m. | Do. do. | 18 do. do. |
| 24 | 8.15 (A.) | Off the surface | Flood tide. Notice sewage coming up with the flood (with soil). Traced it up to Crossness Point, and then over to the other side to Bridge's Powder Magazine. It was seen also in the Blackwall Reach. |

At low water there is a hill near this upper outfall which *stunk fearfully*.
The upper outfall is below the low-water mark: can feel it. It seems to be wood, about five or six feet in breadth, and about the same in height.
During the night near the outfall stunk very much.
All these samples were taken in about the same place.

5106. (*Mr. Lumley Smith.*) When was No. 1 taken?—At midday.

5107. What is your remark about that?—This is near to the upper outfall, about 60 to 70 feet from the quay, and three feet below the surface.

5108. Have you any note about the sewer?—No.

5109. (*Sir John Coode.*) Was the sewer discharging at this time?—That I have made no remark upon, but I have no doubt it was.

(*Mr. Michael.*) It was high water at London Bridge at 11.52 that day.

5110. (*Mr. Lumley Smith, to the witness.*) What is your note as to No. 1?—"Near the upper outfall, "about 60 to 70 feet off the quay, near the centre, "about three feet below the surface."

5111. (*Sir John Coode.*) And you do not know whether the sewer was running at that time or not?—It would be running.

5112. (*Mr. Bidder.*) It was probably running; it was 40 minutes after high water?—That would be my object in taking it from the surface.

5113. (*Mr. Lumley Smith.*) What are the particulars with regard to No. 2?—No. 2 was taken at 1 p.m. near the same place. I have no remark but simply this, "Stinks badly, sewer running."

5114. The next was taken at 2 p.m.?—Yes, it was taken near the upper outfall, from the bottom, 18 feet below the surface.

5115. When was the fourth sample taken?—It was taken at 3 p.m., near the same place, and 17 feet below the surface. At 3 o'clock I felt the outfall, which seemed to be made of wood. You cannot see the outfall, and I had to do it with a line, and I worked my line along, the same as you might work it along the edge of a table, and you could feel then by the chafing of the line that you had come in contact with the wooden sewer.

5116. When was the next sample taken?—At 4 p.m. near the same place, and 16 feet below the surface.

5117. Have you any entry there about the outfall running?—At 3.5 I observed the outfall at the lower jetty running, water discoloured and warm. At 4 p.m. the upper outfall stopped running. At 11.20 p.m. the upper outfall commenced running, and stopped running at 3.30.

5118. (*Chairman.*) You noticed that?—Yes, there is no difficulty whatever in seeing when that outfall is opened. Then it commenced again directly after that, and ran on until 4 o'clock a.m. of the 29th.

5119. (*Mr. Lumley Smith.*) What is your note at 6 p.m.?—There is a fearful mud bank by that outfall. My note is, "There is a mud bank near this upper "outfall which stinks very much." I cannot describe it; it is fearful. The boatman happened to put his oar in there. I had a man and a boy in the boat, and it knocked the boy up; he was ill for a day or two after that. It was really shocking. It is not an easy matter to describe stinks.

5119*a*. Have you any note at 2 a.m.?—At 2 a.m. my bottle caught in the outfall, and I was 15 minutes before I got it clear.

5120. About 4 a.m. it began to be foggy, I believe?—Yes; in fact, it began to be foggy at 9 p.m., and lasted till the next morning, and the next morning it was a beautiful day.

5121. Have you a note as to 8.15?—I noticed the sewage returning on the flood, and traced it from the powder works up to the point at Crossness, and then over to the north shore to Bridge's powder magazine. Saw soil on the south side.

5122. (*Mr. Bidder.*) Where is Bridge's powder magazine?—It is just below these chemical manure works. There are Lawes's manure works and there are Crowe's works, and then comes the powder magazine.

5123. (*Mr. Michael.*) It is below the Barking Guano Works, is it not?—Yes.

5124. (*Mr. Lumley Smith.*) I believe you labelled all these bottles, did you not?—Yes.

5125. And what did you do with them?—I took them to Dr. Tidy.

2126. I believe that during this month you have been taking some other samples?—I have.

2127. On the 16th of this month you were with the medical officer, were you not?—Yes.

5128. Where did you take your samples then?—We were down sampling mud, and I noticed, on going down, that the water was just on the turn.

5129. Did you notice sewage then?—Yes.

5130. How was the tide?—The tide then was just upon the make. It had turned, and was coming up again.

5131. Did you notice where the sewage was going?—Three of the outfalls at Barking were running with great force, and we came right into the line of it in coming from Beckton. All that sewage was passing up the river, and we were going down the river.

5132. That was at a time when the tide was beginning to make?—The tide was making.

5133. And those outfalls were running fast?—With great force, the three upper ones.

5134. How many outfalls are there altogether?—Nine, I think.

5135. When you had the samples labelled what did you do with them?—They were taken to Dr. Beale.

5136. Whereabouts in the river did you take those samples?—I took three samples of mud. I took No. 1 opposite the clock next the pumping station at Crossness; No. 2 near the upper outfall in a line with the jetty; and No. 3 opposite the house between the Government powder magazine and the powder jetty, about 100 feet from that place. There were only three samples taken that day.

5137. Those you labelled and kept separate, I suppose?—Yes.

Cross-examined by Mr. BIDDER.

5138. You say that these three samples are taken from the mud upon the shore; are they taken from mud fresh up from the bottom?—From mud taken up from the bottom of the river.

5139. How far from the shore?—60 feet or thereabouts.

5140. Is the place that you describe as being between the Government powder magazine and the powder jetty, also at Crossness?—Yes, it is just above, this side of Crossness.

5141. About how many feet or yards would it be above the outfall?—It would be 600 or 700 yards, roughly speaking, above the outfall.

5142. That would be round Halfway House Point or Leather Bottle Point.

5142*a*. (*Chairman.*) Was it round the point that you took these samples?—No, I think it was the other side of the point.

5143. (*Sir John Coode.*) A little below the point?—Yes.

5144. (*Chairman.*) On the same side as the outfall?—Yes.

5145. (*Mr. Bidder.*) My Admiralty chart seems to show that the magazine is round the point, above the point?—It would be round the point.

5146. (*Chairman.*) Do you recollect whether it was above or below the point?—(*After referring to the chart*). It is about here (*pointing it out*).

5147. Then it was above Crossness?—Yes.

5148. (*Sir John Coode.*) Then it must be more than 600 yards?—The gentleman asked me roughly, and I spoke roughly. Just for the moment I could not remember where it was.

5149. (*Mr. Bidder.*) As regards the other samples, I think you have sufficiently definitely indicated them. With reference to the condition of the river itself, is it not the case that there are a considerable number of foul outfalls within your district, discharging into the river, quite distinct from the outfalls of the Metropolitan Board of Works?—Yes.

5150. And some of them discharge considerable quantities of sewage?—Do you mean within the jurisdiction of the Port of London Sanitary Authority?

5151. Yes?—Yes.

5152. Is there not a considerable amount of sewage coming from one that has been mentioned, viz., Barking Creek?—Then are one or two small affairs there within the creek.

5153. I do not know how far your jurisdiction goes up the creek; but you are aware that a considerable amount of sewage comes down the creek?—There are some smaller ones, and one larger one, for the relief of the town; but at any time when you are passing up the creek you would not observe any soil floating about that place. There are a few small ones, such as a closet or a privy, and a larger one at the head of the creek.

5154. Does your jurisdiction extend right away up Barking Creek to the river Lee?—No.

5155. Whatever there is above you, you do not take any notice or cognisance of beyond your own jurisdiction?—No.

5156. Do you know one at Beckton?—Yes.

5157. Is there a discharge from that which at times is offensive?—Sometimes it may be.

5158. (*Chairman.*) You have noticed it?—Yes.

5159. (*Mr. Bidder.*) What is the size of that Beckton outfall, by-the-bye?—It is of an egg shape, speaking roughly, about 18 inches in breadth by 23 inches or 2 feet. It is not exactly egg shape, but it is not round.

5160. Do you know higher up where the Blackwall outfall comes into the river?—Yes, at Bow Creek, you mean?

5161. Yes. Is it not the case that you have some very large outfalls there, the sewage of West Ham for instance?—That is the largest of all up there; the others are privies.

5162. What is the size of the West Ham outfall, speaking roughly?—That is a small affair, and you can only see it at dead low water.

5163. You do not know its size?—No.

5164. You know that it drains a large district, perhaps?—I know nothing about the district.

5165. Is it part of your duty to make returns, and to report upon any foul outfalls?—Yes, at stated times, when ordered by the medical officer.

5166. Have you got in your book any memoranda or account, or list of the foul outfalls within your district?—No, I have not any with me; but I can tell you roughly, I think.

5167. Will you tell me roughly how many there are?—Taking the Poplar district, I should reckon that there are at least 40 privies or closets in Poplar.

5168. Then at Limehouse, how is it?—At Limehouse they are getting rather slack; they are clearing away some of theirs. I suppose there would be eight or ten at Limehouse.

5169. Perhaps it would be better not to guess. Have you not in point of fact made reports which are embodied in the reports of the Port of London Sanitary Authority, which will give the exact number?—Yes, I have made reports.

5170. I have here a Blue Book which purports to be a report of the Port of London Sanitary Authority for December last; is that list of foul outfalls on the two sides of the river prepared from your materials?

5171. (*Chairman.*) Was that return made by you?—Yes.

5172. (*Mr. Bidder.*) Is that an accurate return?—At that time it was.

5173. (*Mr. Abernethy.*) What is the date of that report?—December 15th 1881.

5174. (*Mr. Bidder.*) I see that there were 187 on the north side of the river, and 182 on the south

*Mr. W. G. Lewis.*

29 Nov. 1882.

side; and that was accurate at that time. Is it your duty to visit vessels in the river for sanitary purposes?—Yes.

5175. Do you find the health of the seafaring population on the river to be generally good?—Yes.

5176. There is no alarming amount of epidemic disease amongst them?—No; none at present, thank God.

5177. I believe you are rather proud in the Thames of the healthiness of the port, as compared with other ports?—Oh, yes.

Re-examined by Mr. Lumley Smith.

5178. One word about the list of foul outfalls which has been put into your hand. I understood you to say when you spoke of Poplar that there were about 40 there; I see that the number appears in this list as 41?—Well, that is a pretty good guess.

5179. Under the head of foul outfalls are you including closets or privies?—Yes.

5180. This number of outfalls does not mean sewers only?—Decidedly not.

(*Mr. Bidder.*) Some are big and some are little.

5181. (*Mr. Lumley Smith.*) But it does include privies and closets?—Yes.

5182. Have you any materials for showing how many of these, which are all classed as foul outfalls, are sewers, and how many are merely the privies or closets of single houses?—I have no documents with me at present; but if you would allow me I would call your attention to Rotherhithe.

5183. Rotherhithe appears in this list, I think, as having 19?—I venture to say that all but one of those would be closets simply for the waterside houses.

5184. (*Sir John Coode.*) When you say closets you mean for a single house?—Yes; or there might be a second house or a third house that made use of it. That, of course, I cannot say.

5185. Then would you say at most three houses?—That would be pretty well a sewer for three houses.

(*Mr. Bidder.*) I take it that he can scarcely say more than that they are small drains.

(*Mr. Lumley Smith.*) I notice that out of the 187 foul outfalls on the north side, 117 are stated to be within the jurisdiction of the Board of Works, and of the 182 on the south side 59 are said to be within the jurisdiction of the Board.

5186. (*Chairman to the witness.*) In point of fact, whatever return you made, what you mean by foul outfalls is large and small outfalls?—Yes.

5187. (*Mr. Lumley Smith.*) I see that your jurisdiction extends up to Teddington on both sides?—Yes.

5188. You were asked about Bow Creek; have you examined the sewer at all in Bow Creek?—Yes.

5189. There is an outfall of the Metropolitan Board of Works there, is there not?—There is.

5190. Have you ever seen that at work?—Yes.

5191. Was there much sewage coming out?—Yes; foul stuff.

5192. How often have you seen that?—Not so very often.

5193. That is what I believe is called the storm outfall?—Yes.

5194. With regard to Barking, my learned friend asked you whether you took any cognizance of Barking Creek and you answered his question in the negative; have you examined the sewers in Barking Creek?—

(*Mr. Bidder.*) I said he did not take cognizance beyond his jurisdiction.

5195. (*Mr. Lumley Smith to the witness.*) Have you observed the sewers in Barking Creek?—Yes.

5196. Are they large or small?—There is only one sewer to my knowledge.

5197. Does that pour down any substantial amount of sewage?—It is very seldom that I have seen that.

5198. (*Sir John Coode.*) Does Barking itself drain into the main sewerage system?—That I cannot answer.

(*Mr. Bidder.*) It does not.

(*Chairman.*) It continues to be a nest of cesspools as it was a dozen years ago.

(*Mr. Michael.*) It does not join on to the metropolitan system.

(*Mr. Lumley Smith.*) I am told that on other occasions this witness took some other samples which were afterwards submitted to some other gentlemen. I have not the actual particulars of them now; but perhaps, if it is necessary to bring further proof of where they were taken, the Commission will allow me to recall this witness. I have not the materials now.

5199. (*Mr. Bidder to the witness.*) Have you taken samples on several other occasions?—Yes; continually for many years.

5200. During those years you have taken many samples of water and mud, and sent them to different gentlemen for analysis?—Yes, as directed by the medical officer.

5201. Besides those which you have mentioned?—Yes.

5202. (*Colonel Ewart.*) You mentioned the year 1880 as rather an exceptional one, I think; you said that the river was black and disagreeable?—Yes.

5203. Do you recollect whether there was anything exceptional about that year; you spoke of the month of July; had there been drought?—It was dry and hot.

5204. It had been an exceptionally dry year?—Yes.

5205. Do you attribute the exceptional state of the river to that?—I do.

5206. Are you conversant with what are called the storm overflows?—With many of them; I should say very nearly all.

5207. Have you seen them discharging frequently?—Yes.

5208. At all times of the year?—I have not taken that special notice. I have seen them run without rain, some of them; not in a rainy season; but I have made no notes of that.

5209. Have you noticed anything offensive about them?—Oh, yes.

5210. Whereabouts?—For instance, at Blackfriars and up at Deptford. There you can smell it in the Broadway; that will tell you when that is running without going near it.

5211. Would you draw any distinction between the time of the year, whether it was summer or winter?—In the summer I have noticed it.

5212. Are there any others that you could mention that you have noticed?—No, I cannot say that there are.

The witness withdrew.

(*Mr. Bidder.*) The witness has told me that the samples are not all recorded in this book, and that he has another book in which many of them are recorded. I presume that there will not be any objection to his coming again with the records of all the samples that he has taken within the last year or two.

(*Chairman.*) He will bring such books as Mr. Lumley Smith advises.

(*Mr. Lumley Smith.*) Certainly, my learned friend shall see everything. The Commission desired yesterday to have evidence with regard to the eel scoots from some one who is actually in the trade. We have the captain of a Dutch eel scoot, who will be leaving at the end of this week; so we will take him now.

Captain JAN VISSER called in, examined by Mr. BALFOUR BROWNE.

5213. How old are you?—51.

5214. You are a Dutchman?—Yes.

5215. What part of Holland do you belong to?—I belong to close to Harlengen, in Friesland.

5216. And I think you are the captain of a Dutch eel vessel?—Yes.

5217. How long have you been in the trade?—Since the year 1858.

5218. In 1858 were you in the habit of coming up the Thames with eels?—Yes.

5219. In 1858 how far up the Thames were you in the habit of coming?—We generally came in the first spring of the year to Erith till about March or April. Then later in the year we shifted them a little further down.

5220. In the spring you lay at Erith, and when it came to be summer you shifted your boat lower down?—Yes.

5221. Why did you do that?—Only through the bad water.

5222. And the bad water made it necessary for you to stay further down the river during the summer months?—Yes.

5223. Do you remember the condition of the river in the years 1866 and 1868?—Yes.

5224. Was it worse then than it had been in 1858?—Yes; it was getting worse and worse almost every year.

5225. In those years did you find it necessary to go further down the river still?—Yes.

5226. Where did you lie in those years?—We lay at Hole Haven Creek in the spring as we do now.

5227. That is where you lie now, is it not?—Yes.

5228. And you tell the Commission that you lie at Hole Haven Creek both in the spring and summer?—Yes.

5229. Is it owing to the condition of the water higher up the river that you have had to go lower down still?—Yes.

5230. Can you tell the Commission whether eels could live in the water below Woolwich?—No, not below Woolwich. Between Erith and Woolwich is the worst part of it.

5231. How do the eels come up to London from Hole Haven Creek?—In the watermen's boats; in boxes. We wet the boxes pretty well and put eels in them, and then they go up dry in boxes.

5232. In that way they go up to Billingsgate?—Yes.

5233. Can you at any time of the year bring the eels up in your boat to London?—No.

5234. Can you tell the Commission what the value of a cargo of eels may be?—That is all according to what the market is. Sometimes it is a low market, and sometimes it is a high market; it varies from 500*l.* to 800*l.* sterling.

5235. (*Sir John Coode.*) I suppose you bring the catch of several boats?—One vessel carries about 10 tons.

5236. And the catch of how many boats will that represent?—I do not know, I am sure, because we are only the same as traders.

5237. You do not take the cargo direct from the fishing boats, do you?—Sometimes we do, and sometimes we do not.

5238. (*Mr. Balfour Browne.*) It would be a very serious matter if you lost the whole of that cargo?—Yes.

5239. And I understand you to tell the Commission that you now cannot bring that cargo up through the foul water at Woolwich to London, but you are obliged to have the eels packed in boxes and brought up by watermen?—Yes.

Cross-examined by Mr. MICHAEL.

5240. When you were in the habit of stopping at Erith in the summer, where did you stay with your boat in the other part of the year?—We do not stop now.

5241. But in 1864 I mean?—Then we lay just below Erith and sometimes just above Erith.

5242. How far were you obliged to go at that time below Erith in the hot weather?—Then we had to shift them at Gravesend. Sometimes for two or three weeks we might shift them down at Greenhithe, and then we shifted them at Gravesend.

5243. At that time did you take the fish out of the well of your boat and put them into boxes for transmission to Billingsgate?—Yes; so we did when we were lying at Gravesend.

5244. That is 18 years ago?—Yes.

5245. Then that was the practice at that time in the same way as it is now?—Yes, just the same.

5246. But is it not the fact that at the present time, in the colder portion of the year, eels are taken in the wells of the boats to Billingsgate without changing them into boxes?—That is only in the first spring of the year, or in the latter part of the year when we have plenty of rain water. At this time of the year we have generally got plenty of rain water. Then we always reckon that we have seven hours ebb tide and five hours flood tide; and then we have more water coming down from above London than there is on the other side coming up. The more rain water there is, the purer the river will be.

5247. At that time of the year you are enabled to take the fish in the wells without changing your cargo into boxes?—I do not come up with my whole cargo; I come up with part of my cargo during the winter.

5248. During the winter and spring you are enabled to bring part of your cargo up to Billingsgate without changing it into boxes?—Yes, part of the cargo.

5249. Do you not do the same thing in this very month of November?—Now I come up with my cargo.

5250. Do you know that on the 14th of this very month (I do not know whether you have done it yourself) boats have taken the whole of their cargo up in the well without changing any of it into boxes?—Very likely.

5251. Therefore, in the spring months when there is a good deal of water, you are able to do it, and at this time of the year also, you are able to do it in the same way?—Yes.

5252. In the summer-time do you change the whole of your cargo into boxes, or do you take any portion out in the summer?—In the summer-time when the water is bad the whole cargo is brought up in boxes.

5253. What did you do 18 years ago in the summer-time; did not you change it into boxes in the same way?—Yes; 18 years ago we did.

5254. In 1858 what did you do?—In 1858, in the first spring of the year, when we were lying up in Erith, we brought them up in pots until April.

5255. I am going back to the time when you first commenced the trade here; that is 24 years ago; then you were obliged to change your cargo into boxes at some times of the year in order to take it to Billingsgate?—Yes.

Re-examined by Mr. LUMLEY SMITH.

5256. Do you happen to remember where the bad water was 24 years ago?—It was all here in London.

5257. When any of the cargo is brought up in the hold is it brought up by a tug or is it brought up by a sailing boat?—By a tug.

5258. And it passes very rapidly through the water?—Yes; the quicker it goes through the water the better, because when we have to stop too long between Barking and Woolwich, then we have a chance to kill all our cargo.

5259. What would kill it?—The water.

Examined by the COMMISSION.

*Capt. Van Visser.*

29 Nov. 1882.

5260. (*Chairman.*) Are all the eels that you bring over from Holland alive?—Yes.

5261. Then how is it that you send up part of your cargo?—We cannot sell the full cargo in one market day.

5262. Then you send one part one day and another part another day?—Yes.

5263. So that in that way you send the whole of the cargo?—In the summer-time all the cargo.

5264. And in the winter-time what do you do?—In the winter-time we lie here like I have been lying here this time.

5265. Do you not send it up to market?—No; then the people come aboard and buy it off our deck just the same as in summer.

The witness withdrew.

Mr. HENRY SPADACCINI called in, and examined by Mr. LUMLEY SMITH.

*Mr. H. Spadaccini.*

5266. I believe you are one of the inspectors of the Port of London Sanitary Authority?—I am.

5267. I think that at one time you were a mate on one of the General Steam Navigation Company's ships?—I was for four years.

5268. How long have you been an inspector of the Port of London Sanitary Authority?—Since the 1st of July in this year.

5269. How long have you known the river?—I have been at sea over 15 years, sailing from London.

5270. As mate of a General Steam Navigation Company's ship, were you on a ship that went abroad?—I have been on several vessels; some of them went to Hamburgh and some to Bordeaux.

5271. Have you had an opportunity of examining the Thames?—I have had a good opportunity since I have been inspector; and before that I had a good opportunity of seeing the water, but not of examining it closely.

5272. Now I come again to what you have seen since you have been inspector; during the time that you have known the Thames have you noticed any change in the river?—I have not noticed any particular change, because as a boy, I did not take much notice of the state of the river; I had not noticed any difference until during the last 10 years.

5273. Have you noticed it at all during the last 10 years?—During the last 10 years I have.

5274. What is the nature of the change that you have seen?—I have noticed the river being in a very foul state very often. When I was mate in the service of the General Steam Navigation Company I had many opportunities of seeing it, going up and down, and I have heard remarks passed about it by the passengers and others on board on many occasions.

5275. You took some samples, did you not, from the river at Barking from the 28th of July to the 29th?—At Barking I did.

5276. Did you take them every hour from noon on July the 28th to 11 o'clock the next morning?—I did.

*The witness handed in the following paper:—*

TABLE B.

High Water, London Bridge, 11.52 a.m.

PARTICULARS of SAMPLES of SEWAGE, &c. taken at NORTHERN OUTFALL.

| No. | Date and Hour. | | Quality of Sewage. | State of Tide. | Remarks. |
|---|---|---|---|---|---|
| 1 | July 28th | Noon | Diluted | First of the ebb. | Sewage running out strongly; commenced to do so nearly a quarter of an hour before barque "Sloboda," of Trieste, lying in line with outfall, swung to ebb tide, very strong smell; sewage running strongly. |
| 2 | „ | 1 p.m. | do. | 1st hour's ebb Sewage running strongly. | |
| 3 | „ | 2 „ | do. | 2nd hour's ebb Sewage running slowly. | |
| 4 | „ | 3 „ | do. | 3rd „ | Sewage running so slowly as not to be perceptible on surface. Arches uncovering. |
| 5 | „ | 4 „ | Pure - | 4th „ | Arches uncovered three feet. Sewage running out at rate of one knot per hour. |
| 6 | „ | 5 „ | do. | 5th „ | Seven inches of sewage on sill (which is between 65 and 70 feet wide), running out at rate of one knot per hour. |
| 7 | July 28th | 6 p.m. | Pure - | 6th hour's ebb<br>6.45 p.m. Barque "Elsboda" swung to flood tide. | Five inches of sewage on sill, following from Nos. 1, 2, 8, and 9 arches at one knot per hour, and from other five arches at half knot per hour.*<br>Sewage running out from Nos. 1 and 9 arches at a knot per hour, and from remaining seven arches at half a knot to three-quarters; wind very light from southward and eastward. |
| 8 | „ | 7 „ | Diluted | 1st of the flood. | Sewage flowing from end arches and mixing with water of flood tide. From noise inside the arches would infer that a considerable discharge was still going on. |
| 9 | „ | 8 „ | do. | 1st hour's flood. | Large patches of sewage deposit becoming detached from bank to eastward of outfall, and floating up the river with the flood tide. |
| 10 | „ | 9 „ | do. | 2nd „ | A strong smell of sewage noticeable. |
| 11 | „ | 10 „ | do. | 3rd „ | Smell of sewage still present, but weaker. |
| 12 | „ | 11 „ | do. | 4th „ | Do. do. |
| 13 | „ | Midnight. | do. | Nearly high water 0.24 a.m.; high water London Bridge 0.35 a.m. Barque in offing swung to ebb tide. | Strong ripples showing in moonlight that a great amount of sewage was being discharged. Barque in offing still swung flood. |
| 14 | 29th | 1 a.m. | do. | 1st hour's ebb. | Sewage running. |
| 15 | „ | 2 „ | do. | 2nd „ | Not as great a discharge as same tide last time. |
| 16 | „ | 3 „ | do. | 3rd „ | Arches nearly uncovered. Sewage running. |
| 17 | „ | 4 „ | Pure - | 4th „ | Arches uncovered. Sewage pouring out at rate of more than two knots an hour. |
| 18 | „ | 5 „ | do. | 5th „ | 15 inches of sewage on sill running out with great force, say, from four to five knots an hour. |
| 19 | „ | 6 „ | do. | 6th „<br>6.45a.m. water commenced to rise on shore. | Sewage flowing out at rate of nearly two knots an hour, water in river one foot below sill. |
| 20 | „ | 7 „ | do. | Low water<br>7.35 Barque swung to flood. | Barges in offing swung athwart. Sewage running out at the rate of one knot per hour over edge of sill.<br>7.35. Sewage running out at a knot an hour over edge of sill. |
| 21 | „ | 8 „ | Diluted | 1st hour flood | Arches uncovered three feet. considerable noise inside arches similar to what has been going on during discharge of sewage. I consider there was sewage flowing when this sample was taken. Patches of sewage deposit floating up with flood tide on bank to eastward of outfalls. |
| 22 | „ | 9 „ | do. | 2nd „<br>Arches covered. | |
| 23 | „ | 10 „ | do. | 3rd hour flood | — |
| 24 | „ | 11 „ | do. | 4th „ | — |

* Sewers are numbered from above.

5277. Does your book contain entries of the hours and the state of the tide and your remarks?—It does; the entries were made on the day following the days on which I took the samples.

5278. The entries were made, I presume, from notes?—Yes.

5279. Will you tell us exactly where you were posted when you took the samples?—As near as I could get to the outfall when the water got low. When first I commenced to take the samples it was high water; then I got in the place where I saw the sewage rising amongst the other water of the river.

5280. I see that high water at London Bridge is stated to be at 11.52 on that day?—Yes.

5281. Then you began at noon?—Yes, the first sample I took at noon.

5282. That would be the first of the ebb?—The first sample was taken on the first of the ebb.

5283. I see your remark is this; "Sewage running "out strongly, commenced to do so nearly a quarter "of an hour before barque 'Elsboda of Trieste' lying "in line with outfall swung to ebb tide," is that correct?—These entries in my book I made myself on the day following the day on which I took my samples, from notes which I took then.

5284. With regard to that barque "Elsboda," did you notice her moored in the river?—I did; she was anchored immediately off the outfall.

5285. She did not swing to the ebb tide till a quarter of an hour after the sewage had commenced running?—Nearly a quarter of an hour after the sewage had commenced running. The sewage commenced running sometime before 12 o'clock, but the first sample was taken at 12 o'clock. I did not note the exact time when I noticed it first running, nor did I note the exact time when the barque swung.

5286. (*Sir John Coode.*) You are speaking of its being high water at London Bridge at 11.52; it would be high water here earlier?—

(*Mr. Michael.*) About 40 minutes.

5287. (*Sir John Coode to the witness.*) Does it agree with your experience that it is high water here 40 minutes earlier than it is at London Bridge?—I do not think I ever noticed that the difference was 40 minutes.

5288. (*Mr. Lumley Smith,*) At noon you took the first sample?—I did.

5289. Are you able to tell when the sewage commenced running out?—I cannot tell the time when the sewage commenced running out; it commenced before 12 o'clock.

5290. But you do not know how long it commenced before 12 o'clock?—No. I arrived there at, I should think, 20 minutes to 12.

5291. When did you notice this barque begin to swing?—The first sign of the sewage that I saw was nearly a quarter of an hour before the barque swung. This was all before 12 o'clock.

5292. Then would the barque begin to swing as soon as the tide began to ebb?—Undoubtedly, as there was no wind.

5293. Did you notice whether the sewage went up or down the stream when it came out, or what became of it?—I did not notice that.

5294. At any rate the sewage was running out before the barque swung?—Before the barque swung the sewage was running out.

5295. At 3 o'clock, three hours after you made the first observation at noon, your remark is, "sewage "running so slowly as not to be perceptible on sur- "face. Arches uncovering." When the sewage begins to flow out, when the outfall first opens, does it come out under water or above water?—Under water.

5296. How are you able to tell that the sewage is escaping?—By the difference in the water, and not only by the difference in the water but by the smell. It was so bad at 12 o'clock that day that it made me feel sick, and I was obliged to row the boat away to some distance.

5297. Is there anything physical to show that the sewage is escaping?—There is a difference in the colour of the water; it is quite black, a blue black colour.

5298. When you say that the sewage was running out so slowly as not to be perceptible on the surface, there again it would be escaping under water, I presume?—I think so.

5299. What are the arches which you say were uncovering?—Nine arches where the sewage comes out were just uncovering.

5300. I see that at 4 p.m. you first get the quality of the sewage "pure," do you mean pure water or pure sewage?—That is pure sewage, I may have had pure sewage before, but I could not be certain of it.

5301. At 4 p.m. your remark is "arches uncovered "three feet. Sewage running out at rate of one knot "per hour." Were you able at that time to see the sill?—The boat was in on the sill, and I got the samples as the sewage poured out from under the arches.

5302. Why do you say that it was pure sewage?—Because I know it was pure; it was pouring out between the sides of the sewer.

5303. Your bottle was full of the contents of the outfall?—It was.

5304. How do you get your one knot per hour; is that a matter of estimate?—That is only a matter of estimate.

5305. Then I see that at 5 o'clock you get seven inches of sewage on the sill, and it has then been running out about five hours?—Yes.

5306. And I see you say that the sill is between 65 and 70 feet wide?—That is only an estimate too, because I had no means of measuring it.

5307. At 6 o'clock you say there were five inches of sewage on the sill flowing from only four of the arches, viz., arches Nos. 1, 2, 8, and 9, at one knot per hour, and from the other five arches at half a knot per hour: why does it flow more strongly from some than from others?—I could not tell.

5308. Then we come to another entry in which you say at 6 45 p.m. the barque "Elsboda," swung to the flood tide; that you noticed, I suppose?—I did.

5309. The water would be coming up stream then?—Yes, the water would be coming up stream when she swung.

5310. Have you any note showing when this sewage ceased to flow out? At 7 o'clock I see you say that it was diluted, and that the sewage was flowing out from the end arches, and mixing with the water of the flood tide, and that you would infer from the noise inside the arches that a considerable discharge was still going on. Will you describe what you mean by the noise within the arches?—Whilst the water was very low on the sill the boat was grounded close to the arches and there was a noise going on all the time that the sewage was flowing out. After I ceased to see the sewage flowing into the river this noise still continued, so that I inferred that the discharge was still going on.

5311. At eight o'clock you say the arches were uncovered 18 inches and that large patches of sewage deposit were becoming detached from the bank to the eastward of the outfall and floating up the river with the flood tide; those, I suppose, were patches that were on the banks?—Yes, patches lighting off the banks.

5312. When the water was low they remained on the banks?—On one particular bank. This is a bank which lies at the eastern or lower side of the outfall; the greater part of this bank is covered over with small pieces of newspaper that evidently came from the sewers, that drew my attention to it first. They were small pieces; it would take ten of them to cover my thumb nail. When the tide rose some patches seemed to rise up and flow up with the flood tide, and they went up stream. That happened on both tides.

5313. At nine o'clock I notice you state that there was a strong smell of sewage noticeable; were you able to tell whether it was still flowing out?—I could not tell you.

*Mr. H. Spadaccini.*

29 Nov. 1882.

5314. But you smelt the smell?—Yes.

5315. Now I will take you on to past midnight at nearly high water when you say that the barque in the offing swung to the ebb tide with its head southerly; in your remarks you say that there were strong ripples showing in the moonlight that a great amount of sewage was being discharged, and then you say "Barque in offing still swung flood." You judged by the ripples that there was sewage being discharged?—There is no doubt about the sewage being discharged; there was a strong smell and there were ripples or eddies.

5316. Would it go up or down?—It would go up the river; all the sewage that was being discharged would, I think, go up the river.

5317. (*Mr. Michael.*) But did you observe it?—I did not observe it, it was too dark.

5318. (*Mr. Lumley Smith.*) Did you judge by the ripples that the sewage was going up?—No, I did not judge by the ripples that the sewage was going up, but I judged by the way the barque was swung, that the sewage must be going up the river.

5319. I need not take you through all your remarks on the rest of your observations; but going on to seven o'clock, I see you have "low water. Barges in offing swung athwart." What is the meaning of that?—That means that there was no tide where the barges were; that they were lying with their sterns towards shore.

5320. That would be dead low water?—Yes. The water commenced to rise on the shore previously to this. The stream had ceased running down the river.

5321. At the time when the stream had ceased running down the river your note is that sewage was running out at the rate of one knot per hour?—That is true, it was running out over the edge of the sill.

5322. Is the sill visible then?—Yes, quite visible; the whole of the platform is visible then. I do not know what depth of sewage would be running over it, but there was a certain amount running down into the river. The water in the river was below the sill at this time, and the sewage was falling over the edge of the sill into the river. This was about the time when the barges swung athwart.

5323. Do you happen to remember whether it was rainy weather or dry weather about this time?—The day in question was a dry day; we had no rain at all; but I do not remember what was the state of the weather generally.

5324. You had been there on this occasion up to seven o'clock in the morning since noon of the previous day; are you able to say that there had been no storm of rain at all, but that it was a dry day?—There was no storm where we were; it was dry all the time. There was a little fog during the night.

5325. But at seven o'clock, in the morning there would be no unusual storm or anything to keep it running, so far as you know?—No.

5326. But you say that at low water there was sewage coming over the sill?—There was.

5327. On the first hour of the flood I see that you again make the remark, that there was a noise inside the arches, and that in your judgment there was sewage flowing up?—Yes.

5328. On this day it was exceedingly disagreeable where you were; you were just at the outfall?—Yes, close in on the sill; the boat was grounded on the sill for some time.

5329. During those 24 hours the opening of the sluices would happen twice, would it not?—It would.

5330. On either of those occasions in your judgment did the outlet commence before the stream had begun to go down the river?—On both occasions I believe it did.

5331. On both occasions you believe that the sewage came in from the outfall before the stream had commenced to go down?—Yes.

5332. It would naturally go up with the stream?—It would go up with the stream.

(*Mr. Michael.*) We have already had it, that for 40 minutes before the turn of the tide, there is a back current which takes all the water down on the Barking shore.

5333. (*Mr. Lumley Smith, to the Witness.*) Is that your view?—I never noticed it.

(*Mr. Abernethy.*) Is that on the north or the south side?

(*Mr. Michael.*) On the Barking side.

(*Mr. Lumley Smith.*) With regard to this witness again, I believe he took some other samples and, if necessary, I must ask leave to recall him.

Cross-examined by Mr. Michael.

5334. What did you do with the samples that you took upon this occasion?—I took them to the Port Sanitary office at Greenwich.

5335. What did you do with them there?—I did not do any more with them, I left them at our office.

5336. What did you take them in, in glass bottles?—In glass bottles.

5337. Were they all the same size?—All the same size.

5338. What did you do with them when you took them?—I put glass stoppers in the bottles, and tied them down with twine.

5339. Were they numbered consecutively 1, 2, 3, 4, and so on?—They were all numbered the same as they are in the notes.

5340. I presume you have taken a great many other samples, have you not, besides these?—Yes, I have taken some samples since then.

5341. Were these the first?—These were the first.

5342. How many samples have you taken altogether since you took these?—I do not know exactly how many samples I have taken since then.

5343. Have you kept a record in your book of all the samples that you have taken?—I am not sure that I have.

5344. But have you kept any record of any samples that you have taken to the office in these glass bottles?—There is a record taken, but I am not sure whether it is in this book or not.

5345. Could you bring us the record of the whole of the samples?—I could bring it.

5346. Would you be kind enough, when you come again, to bring the record of all the samples which you have taken with the dates in the same way?—I will.

Examined by the Commission.

5347. (*Sir John Coode.*) Are we to understand that the arches are covered as early as the second hour of the flood, as this note seems to indicate?—If the note says so, it is so.

5348. The notes say, "second hour arches covered," that is at 9 a.m.; are they covered at about that period of the flood?—I should think they were; the tide rises very quickly.

5349. You told us just now that it was low water slack at 7 a.m. when the barges were lying in the stream. Am I right in gathering from a note here that the barge swung to the flood at 7.35, and that at 7.35 the sewage was running out at the rate of a knot per hour?—Yes.

5350. Then the conclusion which we are to draw from that is that at 35 minutes after low water slack, and after the barque had turned and swung to the tide, the sewage was running out over the sill?—Yes, the sewage was pouring out over the sill at the rate of a knot per hour.

The witness withdrew.

CAPTAIN RICHARD MARSDEN called in and examined by Mr. BALFOUR BROWNE.

5351. I think you are harbour master for the district of Gravesend?—I am.

5352. How long have you been the harbour master of Gravesend?—About one year.

5353. For three years before that time, I think you were harbour master of the Limehouse district?—I was.

5354. I believe that while you were at Limehouse you very often took Captain Fitzgerald's duty in his district, which is between Greenwich and Greenhithe?—Yes.

5355. And I believe, having had those opportunities you have made various observations upon the state of the river at various times?—I have.

5356. Have you your notes of those observations with you?—Yes.

*The witness handed in the following paper:—*

"REMARKS and NOTES on the FOULING of the RIVER, and ACCUMULATION of MUD in certain parts of the RIVER. From CAPTAIN MARSDEN, HARBOUR MASTER, GRAVESEND.

The fishermen state that they used to trawl for shrimps up Long Reach, and even in Erith Rands good fish were to be caught. Now the bottom is so muddy and the water so foul, that nothing is to be found there.

The eel schoots cannot lie in the river above Hole Haven, and only then inside the haven, as, by the shoal to the westward, the ebb tide is prevented finding its way in, and they only get the *flood* tide water. And when they tow up to London Bridge they shut their valves to prevent the impure water getting to their fish.

An anchor lost in Long Reach is very seldom recovered on account of the mud, and the decks of ships anchoring there are much fouled by the filthy mud adhering to the cable.

The fishermen all speak to the foul condition of the river, and adduce in evidence, that the shrimping boats are all now fitted with boilers to boil the shrimps on board, as they are not able to bring them up to Gravesend *alive* in the wells of the boats.

EXTRACTS from JOURNAL concerning the BAD STATE of the RIVER at various DATES.

June 24th, 1879.—Being soon after I was appointed deputy harbour master of Port of London, perceived a large quantity of sewage coming into river from Ratcliffe Cross outfall. And this was constantly the case whenever there was rain.

September 3rd, 1879.—Being on duty on central station, passing the southern outfall, found the water very filthy with a horrible smell.

February 21st, 1880.—On duty on central station. Observing the drift of the current in Halfway Reach for several days, and having to lean over the side of the boat, and being close to the water, the smell was most offensive and sickening.

July 24th, 1880.—Attending a launch at Messrs. Edwards, Millwall, three-quarters flood, the water was very foul, and off Cubitt Town the stench and state of the river was very bad, a black slimy appearance being on the water.

This was the worst state I ever saw the river in.

September 1st, 1880.—On duty in central station, one quarter ebb off northern outfall, observed the water was in a very bad state, black and stinking horribly. This continued all down Barking Reach.

September 2nd.—Quarter ebb very foul, and stinking fluid coming out of the northern outfall.

September 8th.—River very bad in Halfway Reach; water black, and smell sickening. This continued right up to Blackwall.

September 10th.—Water very bad in Erith and Halfway Reaches.

September 29th.—River very much charged with sewage, worst coming from northern outfall.

October 26th.—Ratcliff Cross outfall half ebb pouring out a great quantity of sewage into river; weather rainy.

April 20th, 1881.—Third storm outlet at Ratcliff Cross.

September 2nd.—Central station. Water much discoloured at sewage outlets.

September 5th.—Found water very foul and stinking from Northern outfall to Erith.

RICHARD MARSDEN,
Harbour Master,
July 18th 1882. Gravesend."

5357. First of all, will you tell me what you observed the condition of the river to be on the 24th of June 1879; I think that was soon after you were appointed harbour master at Limehouse?—Yes, it was. On that day in the morning (I could not give the hour) I perceived a large quantity of sewage coming into the river from Ratcliff Cross outfall.

5358. Have you had an opportunity of observing a similar overflow or outflow upon various other occasions?—Yes, constantly whenever it rains.

5359. Whenever it rains there is an overflow from that outlet?—Yes.

5360. (*Sir John Coode.*) Can you give the size of this outfall, because it is rather material to know whether it is large or small?—It is about four feet broad by above two feet deep, I should think, as far as I could tell.

5361. (*Mr. Balfour Browne.*) Upon the 26th of June at 11.30 on approaching the storm outlet at Ratcliff Cross, I think you observed something?—That I think was a report that I made to the Board.

5362. (*Mr. Michael.*) To whom did you report?—To the Board of Conservators.

(*Sir John Coode.*) There seems to be neither the hour of the day nor the state of the tides in these notes.

(*Witness.*) It was the ebb tide. I can tell you that much.

5363. (*Mr. Balfour Browne.*) And you said it was in the morning, but you could not say the exact hour. It was ebb tide when you observed what you have told the committee?—Yes.

5364. And I understood you to say that you had seen that storm overflow in action at various other times, in fact, whenever it rained?—Yes.

5365. On the 26th of June at 11.30 a.m. you say you observed something; can you tell the Commission what was the condition of the tide at that time?—The tide was three-quarter ebb.

5366. What did you observe?—Approaching the storm outlet at Ratcliff Cross, I encountered a great quantity of sewage matter of the worst possible kind issuing from that outlet.

5367. (*Chairman.*) Is this a memorandum that you made at the time?—This is a report that I made to the Thames Conservancy Board.

5368. Did you make a memorandum upon this subject at about the same time that you observed this?—Yes; this is from what I observed.

5369. What is the date of the paper that you are referring to?—The 17th of July of the same year.

5370. That is nothing but a copy. Have you your own books?—No; there would be nothing in the book about this.

5371. You wrote that paper from memory?—Yes.

5372. Looking at that paper you are able to say that the facts which you have there are quite correct?—Quite correct.

5373. (*Mr. Balfour Browne.*) It was three-quarter ebb when you observed a great quantity of sewage matter of the worst possible kind issuing from this Ratcliff Cross outlet?—It could not have been worse if we had been in the sewer itself. It was just before low water, and as a natural consequence all

*Capt. R. Marsden.*

29 Nov. 1882.

this excrement would be carried up the river with the flood tide floating and being deposited in the higher reaches.

5374. (*Sir John Coode.*) Had there been heavy rain on that day?—There had been rain. I do not say it was heavy rain.

(*Mr. Michael.*) These outlets cannot act without there has been heavy rain.

(*Mr. Balfour Browne.*) That is one of the questions in dispute.

(*Sir John Coode.*) It was stated by one of the witnesses that they did act, and that he had seen them act when there was no rain.

(*Mr. Michael.*) The Commissioners themselves will see the storm outfalls and will see that it is impossible.

5375. (*Mr. Balfour Browne to the Witness.*) I think you reported it to the sanitary inspector?—I met him on the river in his launch and called his attention to it, and he went over there and took samples.

5376. Who is the sanitary inspector?—Lewis.

5377. On the 3rd of September 1879, I think you were on duty at the central station?—Yes.

5378. Where is the central station?—The central station is from Greenwich to Greenhithe.

5379. Then I suppose you were taking Captain Fitzgerald's duty?—I was.

5380. What did you observe upon that occasion?—Passing the southern outfall I found the water very filthy with a horrible smell.

5381. Can you tell what was the time of day and the condition of the tide?—No, I did not make any note of that.

5382. On the 21st of February 1880, I see you made a note?—Yes, I was on duty at the central station again then. Observing the drift of the current in Halfway Reach for several days and having to lean over the side of the boat, and being close to the water, the smell was most offensive and sickening.

5383. (*Mr. Michael.*) How near were you to the outfall?—I was passing the outfall.

5384. (*Mr. Balfour Browne.*) On the 24th of July 1880, I think you attended a launch at Messrs. Edwards; what have you to say about that?—It was three-quarter flood at that time, and the water was very foul, and off Cubitt Town the stench and state of the river was very bad, a black slimy appearance being on the water. This was the worst state I ever saw the river in.

5385. Then I think you as harbour master made a report of that to the Conservancy?—Yes.

5386. On the 1st of September 1880 you were again on duty at the central station?—Yes.

5387. What was the condition of the tide?—At a quarter ebb off the northern outfall, I observed that the water was in a very bad state, black and stinking horribly. This continued all down Barking Reach.

5388. The next day I think you again observed it?—On the 2nd of September I observed again at a quarter ebb a very foul and stinking fluid coming out of the northern outfall.

5389. On September the 8th what did you observe?—On September the 8th the river was very bad in Halfway Reach; the water was black, and the smell sickening. This continued right up to Blackwall.

5390. Then on September the 10th, two days afterwards you were on duty again?—Yes, and on that date the water was very bad in Erith and Halfway Reaches.

5391. What was the condition of the river on September the 29th?—The river was very much charged with sewage—the worst coming from the northern outfall.

5392. Have you a record for October the 26th?—On that date the tide being half ebb the Ratcliff Cross outfall was pouring out a great quantity of sewage into the river. It was rainy weather on that occasion.

5393. Then I see that you have a note for April 1881?—That was a report that I made to the Board. I observed a third storm outlet being made on the shore.

5394. Can you give my learned friend the exact date?—I cannot now.

5395. Then on the 2nd of September 1881, I think you were on the central station again?—Yes.

5396. What was the condition of the river then?—The water was much discoloured at the sewage outlets.

5397. On September the 5th of the same year what did you find?—I found the water very foul and stinking from the northern outfall to Erith.

Cross-examined by Mr. Michael.

5398. Have you ever noticed when the sewage was being discharged, either from the northern outfall or from the southern outfall, that the water was not discoloured by the sewage coming into it?—No, I cannot say that I have. I think it is always discoloured.

5399. I suppose it is a necessary consequence, is it not, of the outfalls being there and discharging sewage that it would discolour the water?—I do not know that it is a necessary consequence.

5400. Have you ever seen it when it did not discolour the water?—I have seen the river very much cleaner at some times than at others.

5401. With the same quantity of sewage being discharged?—I cannot say about the quantity of sewage.

5402. You are not able to say on all these occasions when you saw the storm outfalls discharging, whether there had been a storm or a heavy storm of rain previously?—I could do so by referring to my journal.

5403. You do not know, I suppose, the construction of the outfall?—I do not.

5404. I should be glad if you would furnish the Commission with a statement of the weather as you may have recorded it?—Yes, I will give you all that.

5405. When you speak of the water being of this bad smell and appearance, it has always been somewhere near the outfall itself?—Not always; it is so down in Erith Reach and up at Blackwall; neither place is near the outfalls.

5406. Do you mean as to the appearance or as to the smell of the water?—Of course the smell is not so bad at Erith and at Blackwall, as it is just close to the outfalls; but still it is very bad.

5407. How far do you say that this bad smell, when you have noticed it worst, has extended up and down the river?—I have noted it down as far as Erith and up as far as Blackwall.

5408. Have you ever noticed how far that smell extended over the land?—No.

5409. You are not able to give the Commission any information as to that?—No.

5410. You say that it is part of your duty to be on the river; how many hours do you spend on the river?—Several hours daily; sometimes four, sometimes five, and sometimes six.

5411. Are you brought much in contact with persons who are obliged to remain many hours daily on the river in the pursuit of their avocations?—Yes fishermen and other people of that sort.

5412. What is the general condition of their health so far as you have observed it?—I do not think there is much the matter with them; they look a pretty healthy set of men.

5413. Has it ever been brought to your attention that any special form of disease or difficulty in carrying on their employment has affected those persons who are for many hours every day on the waters of the Thames?—No.

Re-examined by Mr. Balfour Browne.

5414. Is the smell that you have at Blackwall and lower down at Erith the same smell that you have at the outfalls, only fainter ?—Just so.

*Capt. R. Marsden.*

29 Nov. 1882.

Examined by the Commission.

5415. (*Dr. de Chaumont.*) How long have the men in your employ been in that service ?—A long time—several years.

5416. What is the average length of time that a man remains there ?—Some of the men have been seven and eight and ten years, and some of them even twenty years.

5417. You do not know of any who have been obliged to give up on account of sickness ?—I do not think so.

The witness withdrew.

Mr. George Robert Showell called in, and examined by Mr. Lumley Smith.

*Mr. G. R. Showell.*

5418. You are I believe the master of the steam launch "Hygeia" in the service of the Port of London Sanitary Authority ?—Yes.

5419. Have you been for a good many years on the river ?—Yes.

5420. How many years ?—From the time of my apprenticeship; something like 27 years; but I was born and brought up alongside the water.

5421. How old are you now ?—41.

5422. And you have known the river all your life ?—Yes.

5423. I will ask you one or two general questions. Have you noticed any foulness in the condition of the river ?—Many times.

5424. At what times do you find it worst ?—I have seen it on the low water round the bight of East Greenwich.

5425. What have you seen there ?—Other than water.

5426. What is it ?—It is something quite otherwise than water; what I should term sewage.

5427. That you have seen up at East Greenwich, which is above the outfalls, I think ?—Yes.

5428. It is the bight a little below Greenwich itself ?—Yes.

5429. First of all have you seen it at Woolwich ?—Yes.

5430. At what time of the tide have you seen it ?—I have seen it on low water on young flood there again, and on high water particularly.

5431. Anywhere else about that neighbourhood ?—Yes, all along there.

5432. In Half Way Reach have you ever noticed the water in a bad condition ?—I have seen it come out and there stop and go no further but hang on to the eddy at the points.

5433. Have you anchored occasionally off either of the outfalls ?—Many times.

5434. Have you been able to see how long they went on discharging there, having regard to the flowing of the tide ?—It is supposition; it was not sightable.

5435. Was there anything that you could judge by ?—I have seen the colour of the water.

5436. From the colour of the water, should you judge that the outflowing was still going on ?—Yes.

5437. How long have you seen that going on ?—I have seen it at about three parts flood, that is to say, coming out about two hours before high water; and then directly the tide has ebbed two hours it has not gone any farther when the wind has been easterly, or even in calm weather.

5438. You mean that the sewage has not gone down the river ?—It has not gone away at all.

5439. But how long with regard to the tide, have you seen the sewage discharging ?—I have seen it discharging when it has been three parts ebb. That is on supposition; it is not sightable.

5440. You are judging by the colour of the water ?—Yes.

5441. And you have seen it discharging till three parts ebb ?—Yes.

5442. Have you ever seen it discharging later than that ?—It is unsightable on account of water lying there stagnating.

5443. Do you remember one occasion on the 16th of November, 1882, that is this month ?—Yes.

5444. You were rowing Dr. Collingridge down, I believe, were you not ?—Yes.

5445. Did you pass the sewer at Barking ?—Yes.

5446. At what time was it high water at London Bridge on that day ?—Something after five o'clock.

5447. I am told it was at 4·15; but what time was it when you were at Barking ?—A quarter past 12 in the daytime.

5448. Were the sewers at Barking discharging then ?—The sewage was running out of three or four pipes, I think, running out fast.

5449. Was the tide flowing or ebbing at Barking ?—It was flowing then. It was low water about 12 o'clock.

5450. Have you sometimes, in navigating vessels, seen them aground ?—Yes. Formerly we used to bring up at the sewer with something like 12 to 14 feet of water, that is above the Powder House just below Crossness. We could lie there in 14 feet of water. That is a respectable distance from the shore.

5451. Now you find mud there ?—Yes.

5452. What sort of mud is it ?—All loose stuff; of course it is a substance.

5453. What substance is that ?—It is a mixture of mud and something else of course.

5454. Do not be so shy about it; what is the mixture ?—I should say that it is sewage intermixed with mud.

5455. What makes you say it is sewage ?—On account of the stink.

5456. What colour is it ?—A kind of blueish black.

5457. Have you sometimes anchored off Crossness ?—Many times.

5458. In what condition has your anchor been when you have pulled it up ?—I have had a sailor up many-times washing the chain as it came through the hawse pipe.

5459. Was it foul ?—It was covered with the same substance.

Cross-examined by Mr. Norman Bazalgette.

5460. Did I rightly understand you to say that on some occasions you have seen the sewage discharged with the ebb, and then stopped by the east wind ?—Yes.

5461. Does the east wind stop the sewage only, or does it stop the tideway ?—The eddy tide and the wind together stop the sewage from running away.

5462. It stops the sewage and the tide too ?—It stops the sewage and the tide too.

5463. I think you said that you had seen the sewage on low water at East Greenwich ?—Yes.

5464. When did you see that last ?—I have seen it this summer.

*Mr. G. R. Showell.*

29 Nov. 1882.

5465. Can you give us any particular date?—I cannot. I have seen it on several occasions.

5466. Have you seen it more than once this summer?—Yes.

5467. How often?—I should say several times.

5468. Two or three times?—More than three.

5469. How long have you known East Greenwich?—All my life, I might say.

5470. Roughly speaking, what was the condition of the water at East Greenwich 20 years ago?—I was born on the edge of the water at West Greenwich, and we could have fish of all kinds at our back premises. I have seen fresh water haddocks there.

5471. Was that 20 years ago?—Yes.

5472. What was the condition of the water at East Greenwich 20 years ago?—Very good. I have seen freshwater haddocks there then.

5473. You are a good deal upon the water, are you not?—Yes, and always have been.

5474. What kind of health do you enjoy?—Generally speaking, I enjoy good health. I get the air from all quarters. I am not confined to one particular place.

5475. Do you find that you enjoy worse health at East Greenwich than at other places?—I am not there at all times. I live at West Greenwich.

5476. But do you find that you enjoy worse health at East Greenwich than at other places?—I cannot say. I am not there long enough to see.

Examined by the COMMISSION.

5477. (*Chairman.*) Have you ever experienced any faintness or sickness when you have noticed these smells?—I have had very unpleasant smells and tastes too from the spray that has gone into my mouth at different times.

5478. Have you felt anything like sickness or faintness?—No, I cannot particularly say that I have.

5479. (*Mr. Norman Bazalgette.*) (*Through the Commission.*) You say you have occasionally experienced an unpleasant taste from the spray?—Yes.

5480. Was that when you have been anchored off Crossness?—When I have been coming right through Halfway Reach head to wind, with a strong wind.

5481. Near the outfalls?—Right through the Reach.

The witness withdrew.

Adjourned to Tuesday next at half past 12 o'clock.

---

# TENTH DAY.

## Tuesday, 5th December 1882.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ. M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, ESQ., F.R.S., *Secretary.*

CAPTAIN JOHN FITZGERALD, R.N., called in, and examined by Mr. LUMLEY SMITH.

*Capt. J. Fitzgerald, R.N.*

5 Dec. 1882.

5482. I believe you are a Staff Commander in the Royal Navy?—I am.

5483. What office do you hold?—I am at present harbour master of the central station on the River Thames.

5484. What are the limits of the central station?—The limits of the central station lie between Greenwich and Greenhithe.

5485. How long have you been in that position?—Five years.

5486. During that time have you had considerable opportunities of seeing the condition of the River Thames?—I have, almost daily.

5487. In your opinion has there been any change in the course of the last five years in the condition of the River Thames?—I have only known it for five years, and I could not say what it was before.

5488. In the course of your observations have you noticed any change?—Yes; certainly there has been a change for the worse.

5489. What are the symptoms of the change?—During the years 1880 and 1881 it was very much worse than it was in 1878 and 1879.

5490. I will come to 1880 and 1881 a little more in detail; but what is the nature of the deterioration?—The nature of the water was very much worse in 1880 and 1881. At this moment it happens to be comparatively clear; but during the years 1880 and 1881 the water was very much more discoloured and impure than it was during the years 1878 and 1879.

5491. Have you formed an opinion as to what was the cause of that increased impurity?—My opinion is that it is due to the outfalls at Barking and Crossness.

5492. I believe that in the year 1880 it got very bad, did it not, about the month of July?—It was exceedingly bad in 1880, and not quite so bad in 1881.

5493. Your five years would begin in 1877?—In 1877.

5494. Before the year 1880 did you make any careful observations of the state of the river, or was it merely casual observation?—Before 1880 I did. I am speaking from memory now. I took various notes in my journals from time to time when I made these observations, and I could give, and have already given, the days and dates when they were taken.

5495. In 1880 you took special observations, I believe?—I did. The river was worse than it had been, and I took special observations in 1880, and also in 1881.

5496. (*Mr. Bidder.*) Have you your journals here?—Yes, I have all my journals here.

5497. I should like to see them.

(*Witness.*) Will you kindly give me the date you want?

(*Mr. Lumley Smith.*) The 24th of June 1880.

(*The witness produced his journal.*)

5498. (*Chairman.*) These were entries made at the time ?—These were entries made at the time in my journal, which I keep daily.

5499. (*Sir John Coode.*) And the entries were made day by day ?—Yes. My entry for the 24th of June is, "Smell from the river water most offensive, which "continued the entire day. The stream on flood and "ebb apparently charged with sewage."

5500. (*Mr. Lumley Smith.*) Are these observations all made at the same place ?—No. My district lies between Greenwich and Greenhithe.

5501. They are taken within your district ?—Within my district.

5502. What is your entry for the 25th of June ?—"Smell of sewage pervades the river from Charlton to "Erith quite as bad on the flood as on the ebb tide."

5503. What is your entry for the 26th of June ?—"Smell from the river water still offensive, but not so "bad as yesterday."

5504. I think you have no further entry until the 6th of July ?—That is so. My entry for the 6th of July is, "A very offensive smell from the river water "in lower part of the district, especially in Erith "Reach, although the water was comparatively clear."

5505. What is your entry for the 7th of July ?—"River water smelling very much in Erith and Half-"way Reaches, and a good deal discoloured below "Barking."

5506. What is your entry for the 9th of July ?—"River water much discoloured and smelling badly."

5507. (*Sir John Coode.*) To what point did that last remark refer ?—I have not stated specially in what part. It refers to the district generally.

5508. (*Mr. Lumley Smith.*) What is your entry for the 11th of July ?—"Water strongly impregnated with "sewage, and smelling badly."

5509. (*Mr. Bidder.*) Where is that ?—That is in the upper part, off Woolwich. By the upper part I mean that part which lies between Woolwich and Greenwich.

5510. (*Mr. Lumley Smith.*) What is your entry for the 12th of July ?—"Landed at southern outfall "this day to complain of the state of the river. Was "informed the sluices had been opened at the usual "time, a statement which I was inclined to doubt, "owing to the water below the works being com-"paratively clear and the air free from sewage taint, "whereas in Barking Reach it was the reverse." That was at half-flood, I omitted to say.

5511. On that occasion, then, at half-flood, you found the river, below the works, comparatively clear and free from taint, whereas above it was the reverse ?—Yes.

5512. What is your entry for the 13th of July ?—"River water in a very bad state off Charlton and Woolwich."

5513. What is your entry for the 15th of July ?—"River water greatly discoloured with sewage in "Bugsby and Blackwall Reach, and smelling very "badly."

5514. What is your entry for the 17th of July ?—"The river water to-day, both on the ebb and up to "following half-flood, from Woolwich to Erith, was "in a worse condition than I have ever known it. "The water throughout this part, and from side to "side of the river, was heavily charged with sewage, "and the stench almost unbearable."

5515. That is between Woolwich and Erith ?—Between Woolwich and Erith.

5516. What is your entry for the 18th of July ?—"The river water in Woolwich Reach almost black "with sewage."

5517. What is your entry for the 19th ?—"River "much clearer to-day on surface, but bad inshore."

5518. What is your entry for the 21st ?—"River "water this day fairly clear on surface, but filthy and "stinking underneath, every steamer leaving dis-"coloured water in her wake. Immediately above "Leather-bottle Point the water was nearly black at "the last quarter-flood, covering a surface of nearly a "mile."

5519. Before we pass on, I think Leather-bottle Point is what is called Crossness Point ?—Crossness Point, or Halfway-house Point; it has three names.

5520. Did you find on that occasion that although the water was clear at the top that clearness did not seem to go very deep ?—No, it was only surface water.

5521. And that the steamers turned up fouler water underneath ?—Yes, the steamers turned up fouler water as they passed along.

5522. What entry have you on the 22nd of July ?—"River in filthy condition between Charlton and "Erith, and sewage apparently working its way "higher up the river."

5523. Where is Charlton ?—Just above Woolwich.

5524. (*Mr. Bidder.*) Have you your diary for 1878 ?—Yes (*handing it to the learned counsel*).

5525. (*Mr. Lumley Smith.*) Speaking of your entry for the 22nd of July, "Sewage apparently work-"ing its way higher up the river," is that a matter that you can see with your eyes ?—Yes.

5526. It is not a matter of deduction from the set of the tide merely ?—No, you can see it.

5527. What is your entry for the 23rd of July ?—"River from Charlton to Erith in filthy condition at "low water, and the stench abominable. Water during "the whole flood heavily charged with sewage matter "from side to side, nearly black in some places, and "the river, even at high water, above Greenwich full "of sewage, and the odour disgusting."

5528. What entry have you on the 24th of July ?—"River water on surface at high water a little im-"proved."

5529. What is your entry for the 25th of July ?—"River to-day in a beastly state again; William Tur-"nidge" (that is one of the men belonging to my steamer) "sick; attributes it to the river water."

5530. What is your entry for the 26th of July ?—"At low water to-day the river from Bugsby down "was choke full of sewage. Landing-places and fore-"shore full of it. Stench abominable. The same on "flood. Slightly better at high water, but on the ebb "a strong smell of sewage present right across the "river at Woolwich, and the water getting thicker "as the tide fell."

5531. The quantity of water in the stream would diminish as the tide fell ?—It would.

5532. And you say the water got thicker ?—I meant by that expression "thicker" that there was more suspended matter in the water.

5533. What is your entry for the 27th of July ?—"River water tolerably clear at high water this day; "black streaks and patches visible at first quarter "ebb."

5534. One question upon the subject of these black patches. Can you give the Commission any idea of what they were—what was their size for example, and their appearance ?—The patches varied considerably in size, some were large and some were small. Some were patches of about the size of this room, others were six times as large. They were all over the river.

5535. You mention that they were visible at first quarter ebb; did you form any opinion as to why they became visible ?—I was under the impression that it was the clean water being swept away from the surface and leaving patches of the dirty water underneath.

5536. Those were patches that had been suspended below the surface ?—Yes, that is what it appeared to me to be like.

5537. That is to say, they were not in sight at the full flood ?—They came up on the first quarter ebb, as the clean water was swept away down the river.

5538. Did you examine them at all ?—I did not take any samples of those patches.

5539. You formed an opinion as to what they were composed of ?—Yes; I formed the opinion that it was sewage.

5540. What is your entry on the 28th of July ?—"River water improved off Charlton, but full of

*Capt. J. Fitzgerald, R.N.*

5 Dec. 1882.

" sewage in Barking and Halfway Reaches at half ebb.
" Patches of sewage all over Long Reach and smell-
" ing badly."

5541. What is your entry on the 29th of July?—
" Water in river rather better to-day, owing to the
" prevalence of strong westerly winds. Surface water
" fairly clean and free from smell."

5542. What is your entry on the 30th of July?—
" Water in river continues to improve, but the fore-
" shore and some of the landing-places are clothed
" with sewage mud."

5543. What is your entry on the 31st of July?—
" River water continues to improve."

5544. What is your entry on the 4th of August?—
" Water in the river to-day much improved and free
" from smell, excepting in Halfway Reach."

5545. What is your entry on the 5th of August?—
" River water fairly clean to-day and free from
" smell."

5546. What is your entry on the 13th of August?—
" River water this day smelling badly. Patches of
" sewage visible throughout the district, especially at
" first quarter flood."

5547. Have you read the whole of that?—That is all I can see here.

5548. What is your entry on the 20th of August?—
" Water in river continues to remain fairly clear and
" free from smell."

5549. What is your entry on the 21st of August?—
" Water to-day fairly clear, but smelling badly at low
" water."

5550. What is your entry on the 27th of August?—
" River water throughout the day, both on the ebb
" and flood, smelling strongly of sewage, and black
" patches to be seen in various parts of the river."

5551. That is the last of your observations, I think, about that time?—Yes.

5552. How came you to take these almost daily observations?—The river was so excessively bad at that time that I thought it my duty to take observations daily.

5553 And from time to time you reported?—Yes; I reported from time to time to the Conservators.

5554. I may take it that after August it improved somewhat?—Yes; I went away at the latter end of August. I generally go away then for a month, and another gentleman takes my place, and he took observations, I believe, in my absence during the whole of September.

5555. (*Mr. Balfour Browne.*) We have had Captain Marsden, who took your place?—Yes; he took my place on that occasion.

5556. (*Mr. Lumley Smith.*) Was this a hot time?—In 1880 it was the worst time.

5557. In this particular July that you have been given us, was it hot weather?—Yes, it was hot, sultry weather.

5558. I think you have a note in your book in October?—I was back in October. I have an entry then. "River water charged heavily with sewage to-
" day, especially in Erith and Halfway Reaches. Air
" bubbles visible right across the river."

5559. I think that hot weather came again in the following year, did it not?—In 1881 we had some hot weather.

5560. Did you find a recurrence of the same class of annoyance?—Just the same; it was not quite so bad as in 1880, I think, but it was very bad even in 1881.

5561. I think you have a few notes of your observations during that hot time in July 1881?—Yes.

5562. (*Chairman.*) From October until the following July you did not observe anything offensive in the condition of the river?—Not so bad as it was in the summer. I think I made notes from time to time, but there were not very many notes made. The water was cool, and of course the state of the river is very different in winter from what it is in summer.

5563. (*Mr. Lumley Smith.*) In the autumn is there more or less fresh water coming down?—I think there is more as a rule then.

5564. And it is cool?—Yes.

5565. At any rate the bad time comes in very hot weather?—Yes, in hot, sultry weather.

5566. Will you read the entry that you have for the 14th day of July 1881?—" River water heavily
" charged with sewage and smelling badly."

5567. What entry have you on the 15th of July?—
" River water smelling badly and much discoloured
" with sewage."

5568. What is your entry on the 18th of July?—
" River water this day offensive and heavily charged
" with sewage."

5569. What is your entry on the 19th of July?—
" River water this day in filthy condition, especially
" between Blackwall and Purfleet."

5570. What is your entry on the 20th of July?—
" River water in very bad state."

5571. What is your entry on the 21st of July?—
" River water throughout the whole district this day
" in a filthy condition from sewage."

5572. What is your entry on the 23rd of July?—
" River water in an exceedingly bad state, even at
" high water."

5573. What is your entry on the 25th of July?—
" River water in filthy condition at half ebb, and
" smell most offensive."

5574. What is your entry on the 26th of July?—
" River water very filthy at half ebb, heavily charged
" with sewage."

5575. (*Sir John Coode.*) In what part of the river?—When I have not distinctly stated the part of the river, I mean that it is generally so throughout the district.

5576. (*Mr. Lumley Smith.*) What is your entry on the 27th of July?—" River water heavily charged
" with sewage."

5577. What is your entry on the 28th of July?—
" River water very offensive this day, especially off
" Erith and Woolwich."

5578. What is your entry on the 30th of July?—
" River water this day rather better, and the smell
" not so offensive."

5579. Your next entry is on the 2nd of August; what is it?—" River water very filthy at half tide, and
" the odour very offensive."

5580. What is your entry on the 5th of August?—
" River water this day very offensive and full of
" sewage."

5581. What is your entry on the 6th of August?—
" River water full of sewage, and the odour very
" offensive."

5582. What is your entry on the 8th of August?—
" River water this day rather cleaner, and not smell-
" ing so badly."

5583. What is your entry on the 9th of August?—
" River water same as yesterday."

5584. What is your entry on the 10th of August?—
" River water on the ebb in a filthy state, especially
" in Erith and Halfway Reaches."

5585. What is your entry on the 12th of August?—
" River water heavily charged with sewage, and smell-
" ing badly at half flood."

5586. What is your entry on the 19th of August?—" At $2\frac{3}{4}$ hours before high water this evening sewage
" from the northern outfall in Barking Reach was ob-
" served to be flowing into the river, a sample of
" which was obtained in front of the works by George
" Lamerton and Thomas Long, watermen of the Con-
" servancy; time, 6.40 p.m."

5587. (*Sir John Coode.*) At what time was it high water on that day?—That was at $2\frac{3}{4}$ hours before high water.

5588. (*Mr. Lumley Smith.*) Have you the time of high water there?—High water would be about 25 minutes past 9 on that day.

5589. I think your entry on the 20th of August is, that two men were employed during the night?—Yes. " Two hands employed during the night tide to
" take samples of river water at the metropolitan out-
" fall in Halfway Reach."

5590. What is your entry on the 21st of August?—" Two hands at northern outfall, Barking Reach, at

" half-flood night tide. Reported sewage coming " through the sluices at 9.30 p.m. High water at " 11.35."

5591. Could you give us the names of those two men?—George Lamerton and Thomas Long. They are both here.

5592. What is your entry on the 23rd of August?—" Two hands in harbour boat attending at northern outfall during the night flood tide; observed sewage " coming through the sluices at 11 p.m. Sample " taken."

5593. Who were the men?—George Lamerton and Thomas Long.

5594. What is your entry on the 24th of August?—" Two hands in harbour boat at the northern out- " fall during the night flood tide."

5595. On the 25th there is a similar entry as to the southern outfall?—Yes.

5596. Then I believe you went away on leave through September?—I went away on leave in September.

5597. I think you have an entry in October of that year, after you came back from your vacation?—I have, " Sewage from northern outfall very offensive " this tide." That is on the 19th of October.

5598. You have a few, I think, in 1882; this year?—Yes.

5599. Have you an entry on the 17th of March 1882?—Yes. " At the last quarter ebb to-day the " river in Halfway Reach and off Erith was in a very " foul state and smelling badly."

5600. On the 30th of June what entry have you?—" At 9 o'clock this morning the river water off " Charlton was very offensive, and smelt strongly of " sewage at two hours flood."

5601. Charlton is above Barking, is it not?—Yes, it is above Woolwich.

5602. What is your entry on the 10th of August?—" River water to-day at last quarter ebb in Halfway " Reach was very turbid and full of air bubbles, " giving off an offensive odour."

5603. What is your entry on the 28th of August?—" River water in Halfway Reach and off Erith very " much discoloured and smelling badly."

5604. Then I think you went away again in September?—I did.

5605. Then you have an entry on the 26th of October; what is it?—" Water in Barking Reach to- " day heavily charged with sewage and smelling " badly."

5606. Did you make a point of making entries about the river during the rest of the year as well as in the two Julys and Augusts, when you seem to have made almost daily observations?—No, I confine myself more to the summer months.

5607. What was your practice as to making entries about the river, and when did you begin to make those entries?—I think I commenced in 1878, the year after I first came to the Thames.

5608. As those were the two bad months, you have put them down very carefully?—Yes, especially in 1880 and 1881.

5609. Has not the water been so bad in 1882 as it was in previous years?—No, it has been exceptionally clear, as it is now.

5610. Can you account for that in any way?—The way in which I account for it is, that we have had very strong winds from the west and south-west, and a great deal of rain.

5611. You have told the Commission that you think this foul condition of the river is caused by the sewage; are you able to tell them from what particular parts or places the sewage comes?—The sewage comes through the northern outfall just above Barking Creek, and it comes through the southern outfall just below Crossness Point.

5612. Is it sewage that has come down the river from above bridge, or is it sewage that has come from below from the outfalls?—My opinion is that it is the sewage that comes from the outfalls.

5613. I believe you did make some observations in the year 1878 on the depth of the mud found in different places, did you not?

(*Mr. Bidder.*) I would remind my learned friend that this witness gave these observations in evidence upon the last inquiry.

(*Mr. Lumley Smith.*) I propose to hand the statement in, but not to take it through the witness. This statement gives the depth of the mud found at various places on the 18th of December 1878.

(*Mr. Bidder.*) In the first place, it takes a considerable time, and if it is material, it would be my business to cross-examine upon it; and besides, it is simply going back to an exhaustive inquiry which has already been held, and upon which a decision has been given.

(*Chairman.*) Not by us.

(*Mr. Bidder.*) I do not mean to say that the Commission are stopped from going into it; but I put it to the Commission and to my learned friend whether, under the circumstances, it is worth while to re-open an inquiry which has been thoroughly threshed out.

5614. (*Chairman, to the witness.*) What are these observations?—These are observations that were taken in the year 1878.

5615. By yourself?—By myself. (*The witness handed in the following statement.*)

DEPTH of MUD found in the following PLACES, 18th DECEMBER 1878.

WOOLWICH REACH.

Just outside the line of mooring buoys off the Dockyard:—

Abreast of Lower Graving Dock, 5 ft.
Ditto of Upper Graving Dock, 8 ft.
Ditto of No. 2 Crane, 9 ft.
Ditto of Clock House, 9 ft.
Ditto of Landing Stage, 7 ft.
Ditto of Lower Building Shed, 8 ft.
Ditto of Charlton Pier, 5 ft.
Ditto of Siemen's Telegraph Works, 8 ft.

BARKING REACH (Essex shore).

Just above Farmer's Teeth, 150 ft. from low water, 12 ft.

400 feet from low water, and off the pitch of Crossness Point, 12 ft.

500 feet from low water off the pitch of Crossness Point, 10 ft.

120 feet from low water abreast of 2nd fence below magazine, 8 ft.

120 feet from low water, midway between upper and lower fences, 10 ft.

120 feet from low water, abreast of upper fence, 11 ft.

120 feet from low water, between magazine and upper fence, 10 ft.

120 feet from low water and abreast of magazine, 7 ft.

HALFWAY REACH.

Mid-Channel, 18th December 1878.

Tide gauge in with No. 2 chimney, 10 ft.

Fountain, midway between 2 chimneys in grounds, 8 ft.

Abreast of main shaft, 9 ft.

Mid-Channel, 20th December 1878.

Off Powder Creek, 7 ft.

Abreast of mud shoot, 9 ft.

One quarter off, 20th December 1878.

Abreast of main shaft, 12 ft.

ERITH REACH.

At Erith Pier, 20th December 1878, 5 ft.

120 feet from end of Causeway, 20th December 1878, 11 ft.

*Capt. J. Fitzgerald, R.N.*

5 Dec. 1882.

120 feet from low-water mark, 20th December 1878:—

Lower Ballast Wharf, 15 ft.
Upper Ballast Wharf, 10 ft.
Gas Wharf, 12 ft.

NOTE.—20th November 1882. Steamship "Fatfield" was in collision, owing to which she was ran ashore on the Essex side of Barking Reach, just above the Farmer's Teeth. The vessel ebbed dry at low water; but embedded herself in mud nearly 12 feet.

5616. (*Sir John Coode.*) What was the general result of these observations; was it that there was any addition to the accumulations or not?—I think it went to prove that the mud was increasing in the river.

5617. That is the general conclusion that you drew from these observations?—That is the conclusion that I drew.

5618. (*Mr. Lumley Smith.*) Are you able to tell us of what this mud was composed?—My opinion at the time was that it was composed mostly of sewage.

(*Mr. Bidder.*) I object to that, unless he has made an analysis.

5619. (*Mr. Lumley Smith, to the witness.*) You made no analysis of the mud, I understand?—No, not personally.

5620. Are you familiar with Thames mud?—I am.

5621. Was this mud that you found here of the same character as Thames mud, or did it differ in any important particular?—It varied in character apparently. In some places it was black, stinking mud, and in other places it was not quite so bad.

5622. I see that your list which has been handed in does not state the character of the mud at different places?—No. Samples were taken at these places from time to time, and they were analysed by those who were able to do it.

5623. Of course the important ingredient in this inquiry is whether it was sewage or what it was. One more question on the subject of depths. Quite lately, I believe, there has been a steamship, the "Fatfield," in collision?—Yes, I think I have a note of it in my journal.

5624. On the 20th of November 1882, a fortnight ago, what is your entry?—"The 'Fatfield' was in col-
" lision in Halfway Reach, and was compelled to run
" ashore to avoid sinking, and she embedded herself
" in 12 feet of mud in Horseshoe bight."

5625. Did you see that yourself?—I saw it myself.

5626. What was the nature of the mud there?—It looked like black, stinking sewage mud, the whole of it.

(*Dr. Stevenson.*) Where is Horseshoe Point?

(*Mr. Bidder.*) It is just opposite Leather Bottle Point.

Cross-examined by Mr. BIDDER.

5627. I believe that the depths of mud which you have now handed in to the Commission are the same observations that you took for the purpose of the inquiry which was held in the year 1879?—Quite so.

5628. In which your masters, the Conservators, charged the Metropolitan Board with having caused large mud banks in that part of the river?—Yes.

5629. I should just like to identify them. One was a large mud bank opposite Crossness outfall, from there up to Leather Bottle Point on the south side of the river?—Yes.

5630. And another was a mud bank in that place which you have just mentioned, Horseshoe bight, at Dagenham?—Yes.

5631. And another was at Margaretness, a little higher up the river?—Yes.

5632. And you not only took observations but you gave evidence before the arbitrators in that case, Sir Charles Hartley, Sir Frederick Bramwell, and Captain Galton?—Yes.

5633. And all these figures were before them?—Yes.

5634. As you say, you did not analyse the mud, but the mud was analysed by other people who gave the result of their observations?—That was so.

5635. Perhaps it is within your knowledge that the result of these proceedings was that the arbitrators decided———

(*Chairman.*) Surely the arbitrators' decision was in writing.

5636. (*Mr. Bidder, to the witness.*) I merely want to get the fact from you; that what you are putting in now is nothing more than what you gave in evidence on the former arbitration as regards that part of the case?—That is so.

5637. First as regards your opinion as to what you call sewage and the offensive matter which you observed in the river, principally I gather between Charlton and Woolwich, when you express an opinion as to where it comes from, may I take it that that is a mere question of inference, and that it is not from tracing it to one place or the other. Of course we all know that you or anybody else can see large volumes of sewage pouring into the river at Barking and Crossness. May I assume that you infer where it comes from?—I take it for granted, in consequence of what I see.

5638. I understand that you have been, since the autumn of 1877, stationed in that part of the river?—Yes.

5639. And I think it was in the winter of 1879 that you gave evidence on the last inquiry?—I think it was.

5640. And you expressed at that time a strong opinion adverse to the effect of the metropolitan sewage, not only as regards the fact of the mud banks, but as regards the offensiveness?—I almost forget whether I expressed any opinion with regard to the sewage. I think the inquiry at that time had reference to the banks of mud.

5641. But it had reference to the cause of them?—Yes.

5642. And you expressed an opinion as to the offensive results produced by the sewage?—Yes.

5643. If I recollect rightly, you were cross-examined, and you adhered to your opinion and took a very strong view upon the subject—I do not say unnecessarily strong. Am I right in supposing that until after that time there are practically, with one or two exceptions, no entries in your diaries of any particularly offensive condition of the water?—So far as I remember, I commenced to make entries in my journal shortly after I came into the river, in 1877. I think I commenced to make entries before 1878.

5644. One part of your diary you have sealed up, for some reason or other, so that I have not looked at that?—Those were my predecessor's observations, and I sealed them up because of course I could not be responsible for anything he said.

5645. So far as I have seen, there is no entry of the water being in a bad condition before 1879. Of course I do not pretend to say that I have read the entries exhaustively?—I think, so far as I know, I put them all down on this paper, but I will not be quite sure. Perhaps you will allow me to look at it. My observations were more particularly directed to the subject in the years 1880 and 1881, because the river was then at its worst.

5646. Let us get at the facts first, and then you can make any explanation you please afterwards. What entries have you before the year 1880?—The following are extracts from my journal as harbour master of the central district for the years 1878 to 1882. " On the 20th of December 1878, tides very sluggish,
" owing to which the water in Halfway Reach and
" also in Barking Reach was found to be in a very foul
" state, and heavily charged with sewage."

5647. What is your next entry?—The next is on the 2nd January 1879. "Tide sluggish, water in "Halfway Reach heavily charged with sewage matter;" and on the 16th of July, "Watchman on board the "steamer 'Conservator' at Charlton reports a strong "smell of sewage round the vessel on the flood tide." On the 19th of July the entry is, "a strong smell of "sewage round the vessel at her moorings, and the "water presenting all the appearances of being charged "with sewage matter."

5648. Is that also the report of the watchman?—No, it is my own observation.

5649. What vessel is that?—On board my own vessel at her moorings at Charlton. That is all I have in the year 1879.

5650. Those three observations are all that you have until the 24th of June 1880?—Yes.

5651. I think you have also some observations in your diary, which you have not extracted, of an opposite character as to the remarkable purity of the river at certain times, have you not?—I am very sorry to say that it is not often in such a state as to justify such a statement.

5652. (*Chairman.*) Have you any such entries?—I think I have one, and it must be three years ago since I made such an entry; and then it was in Long Reach.

5653. (*Mr. Bidder.*) You did not think it worth while to extract it?—I did not think it worth while to extract it, because it is the only observation of that character that I ever made. It is in my journal, but I could not put my finger upon it at this moment.

5654. Will you turn to the 17th of March 1879?—I think that bears out what I said. "Ebb tide very "sluggish, and water in the river very clear off "Greenhithe." I think that was the observation that I made about three years ago.

5655. Will you try the 1st of April?—"To-day the "river water was remarkably clear throughout the "whole district, especially between Erith and Green-"hithe. Tide sluggish." You see I marked it in order to give it if it was required.

5656. Then the next entry you tell us is on the 24th of June, and then we have got all the others down upon the notes. I am not going through them in detail; but when you speak of the water being "charged with sewage" (or similar expressions), I want to know exactly what it is that you intend to convey; was it discolouration, or muddiness, or what?—The answer to that is, that I considered that the water was full of sewage from its containing a lot of suspended matter which was really like sewage. It was my opinion that it was sewage.

5657. You inferred that it was full of sewage from its containing suspended matter?—Yes.

5658. Then, again, you have spoken several times of the smell of the water; I want to get a distinct understanding about the foundation for that. I will take, for instance, one of your last entries. You said that on the 10th of August 1882, at the last quarter of the ebb in Halfway Reach, the water was turbid and full of air bubbles, all across the river, and smelling; how did you make that observation?—I saw it with my own eyes, and I smelt it.

5659. You could not see a smell?—No; but I saw the bubbles with my eyes, and my nose told me that there was a very unpleasant smell.

5660. Were you in a vessel on the river?—I was in my own boat.

5661. In the Conservators' launch, I suppose?—In the Conservators' launch.

5662. Going up and down in the district?—Going up and down in the district.

5663. Perhaps you will tell me also how you happened in the summer of 1881 to be watching the outfall at night?—The river was in a very filthy state, and I wanted to ascertain the reason; and I was under the impression that the sluices must have been open on the flood tide to produce such a state of things. Accordingly I sent two of my men (who are both here) during the night tides to find out if such was the case.

5664. (*Chairman.*) Did you go yourself?—Not during the night tides. I have seen the sluices open during the day tides on the flood; but on this occasion I sent two men.

5665. (*Mr. Bidder.*) One other thing that I want explained is this: when you say "water clear on the "surface, and filthy and stinking underneath," how is that observation made?—If you were to go in the wake of a steamer going down the river on these occasions you would see that the lower part was stirred up by her screw, and you would find that that which was stirred up was in a stinking, filthy condition, whereas that which was upon the surface was comparatively clean.

5666. Then that is from observations in the wake of steamers, and other observations of that character?—Just so.

5667. Will you tell me where that observation was made?—It was made in almost every part of my district, excepting in Long Reach; I do not think I could apply such an observation to Long Reach.

5668. It is put upon a particular day. Let me see your diary for that day, the 21st of July 1880?—"River water this day fairly clean on surface, but "filthy and stinking underneath."

5669. That is the date. Will you let me see your diary (*the diary was handed to the learned counsel*); can you say from your diary what part of the river that particularly applied. I see you were in Jenningtree Reach?—Yes; at that time of the year I should think it applied to every part of the river within my district except Long Reach.

5670. I see by your diary that you were off Jenningtree Point examining sand barges, or doing something of that kind?—Yes.

5671. You cannot tell me from memory at what particular part of the river it was, but you express a general opinion that it would apply generally?—Yes; so far as I recollect it would apply to every part of my district above Long Reach.

5672. On the 22nd of that same month, I think you speak not only of the water being better, but of the sewage "apparently working up;" will you give me an explanation of that phrase?—What I meant by that was that as the season advanced, and as the sewage became worse in the river, so it extended itself upwards. First it was not so bad above Woolwich. It then was not so bad above Charlton. Then it worked its way to Blackwall. Lastly, it got as far as Greenwich.

5673. But that rather puzzles me, because that day's entry speaks of its being bad between Charlton and Erith?—On the 22nd this is the entry, "River in "filthy condition between Charlton and Erith, and "sewage apparently working its way higher up the "river."

5674. That is what puzzles me, because you say that that means going up as the season advances. If I took your answer down rightly, the week before that you had recorded it as very bad in Bugsby and Blackwall Reach, which is higher up still?—Yes, but I do not think I made use of the words "filthy condition" in Bugsby and Blackwall Reach.

5675. I have not your scale of gradations of terms of abuse, but you used some such phrase. Will you look at your entry on the 15th?—On the 15th the entry is "River water greatly discoloured with sewage "in Bugsby and Blackwall Reach, and smelling very "badly," whereas on this day it is "filthy."

5676. Have you noticed the river at the present time?—I have; I am on the river almost every day.

5677. What is its condition now?—Very much better; better than I have seen it for three years.

5678. Is it charged with sewage?—I have no doubt there is a great deal of sewage in the river; in fact, I am sure there is.

5679. That we all know, seeing that it is poured in twice a day from two great outfalls?—But appa-

*Capt. J. Fitzgerald, R.N.*

5 Dec. 1882.

rently the river is cleaner or sweeter than it has been for three years.

5680. Is there, to your observation, anything offensive about it at the present time?—Speaking generally, no.

5681. You have observed nothing offensive in this present year, excepting upon those days which you have recorded?—I will not say that. Upon those days when I recorded it, it was very bad; and there were other days when it was bad too, but when I did not consider it necessary to make any observation in my journal.

5682. Did you ever examine the black patches which you spoke of upon one occasion, and which you say were the size of this room, or larger, in order to see what they were composed of?—I have steamed through them; I have gone through them in my boat hundreds of times.

5683. Are they a novelty upon the river; have you known the river in olden times?—No, I cannot say that I have known the river very long. I knew it years ago, before the metropolitan sewers were constructed, but I did not know so much about it then as I do now.

5684. You knew it generally?—Yes; I was occasionally upon it in river boats.

5685. I gather that you have never analysed or examined the sewage?—Not personally.

5686. Have you ever taken any observations of the temperature of the water?—I have.

5687. Have you got them recorded?—No, I cannot say that I have ever recorded them; but I have taken observations for my own private information.

5688. For instance, on those occasions in the summer time, have you recorded them?—No, I have not recorded them, but I have taken observations of the temperature of the sewage and of the clear water, when it was clear. I have found a very great differ, ence between the temperature of the water when it was heavily charged with sewage, and its temperature when it was apparently clean, as much as eight or nine degrees.

5689. Sewage has a warming effect; but as a matter of fact can you give me from memory what temperatures you have observed?—I cannot; they vary very much.

Re-examined by Mr. Lumley Smith.

5690. I think you told us that you employed these men in August 1881 to take samples at the outfalls, and to watch the outfalls?—Yes.

5691. What was done with the samples?—The samples were submitted to the Conservators, and I believe they gave them to their analytical chemist.

5692. The men brought them to you?—The men brought them to me, and I submitted them to the head office at No. 41, Trinity Square, where they were, I believe, transferred to the analyst.

5693. (*Chairman.*) You gave them to somebody?—I gave them to the Conservators.

5694. (*Mr. Lumley Smith.*) I see that on two occasions the men reported sewage coming through; would that be by word of mouth, in the morning?—They brought their reports to me in the morning; I believe they made notes at the time.

5695. (*Chairman.*) The question put to you was, did they deliver their reports to you by word of mouth or in writing?—They reported to me verbally.

5696. (*Mr. Lumley Smith.*) Do you remember whether the year 1879 was a warm or a cold year?—I cannot say that I remember.

Examined by the Commission.

5697. (*Chairman.*) You say that you went with your boat through these black patches?—Yes.

5698. You saw those patches; did you smell them?—Yes.

5699. From what your eyes told you, and your nose told you, what inference did you draw as to what those patches were?—That they were patches of sewage.

5700. (*Sir John Coode.*) You handed in a statement from which, if I rightly understood you, you said that you drew the general conclusion that there had been an accumulation of mud; was that so?—That is when these observations were taken.

5701. But this statement goes to December 1878, and to December 1878 alone. I do not see how you can draw from a statement confined to a single month the conclusion that there had been an accumulation. Probably there is some further statement, which is missing from this one?

(*Mr. Bidder.*) It is right to say in justification of the witness that we compared these soundings with old Admiralty soundings.

(*Witness.*) I do not think I have made entries of any previous observations, but being on the river every day, as I am, I go probing about here and looking yonder in all parts through my district, and I make observations in my mind as to the state and condition of the district generally; but I have not made any entries in my journal of the depth of the mud, excepting these.

(*Sir John Coode.*) This statement is handed in, and you said in reply to a question that you drew the general conclusion from it that there had been an accumulation of mud. Taking this statement *per se*, it is impossible to draw any conclusion one way or the other, because it refers only to a single month; I should imagine that there are some further observations upon which you have instituted your comparison.

(*Mr. Bidder.*) The witness omitted to say that he drew the conclusion comparing these soundings with the previous condition of the river.

5702. (*Chairman, to the witness.*) I understand you to say that you have been about the river since you took these observations?—I have been about the river ever since I took them. These observations were made in the year 1878, and I have been on the river ever since.

5703. You said just now, in answer to Sir John Coode, that you had drawn the inference that there had been an accumulation; when did you draw that inference?—When these observations were made.

5704. You made certain observations in December 1878?—Yes.

5705. Now you say that you infer that there has been an accumulation?—Yes.

5706. Was the inference that the accumulation had been made in December 1878?—No, not confined to that month.

5707. (*Mr. Abernethy.*) I understand that these observations were made with a view of comparing the state of the river at that time with the previous charts?—Just so.

(*Sir John Coode.*) With that explanation we understand what it means; but as this statement is put before us, accompanied by an answer by Captain Fitzgerald to the effect that he drew from this the conclusion that there had been an accumulation, I say that this statement does not show that, one way or the other; but an explanation has now been given which clears it up.

(*Mr. Bidder.*) There is no dispute as to the fact.

(*Witness.*) I have a thorough knowledge of the charts and of the recent surveys.

5708. (*Sir John Coode.*) Did you institute a comparison between 1878 and the present date, or a subsequent date, or between 1878, and some previous date?—Between 1878 and some previous date.

5709. What is that previous date?—It extended over a great many years. The surveys of the river have taken place from time to time, and I compared the depths of the water and the mud which I obtained with those surveys which were obtained previously, and recorded in our office; and I could see the difference, and it was from that that I drew my conclusion.

5710. (*Chairman.*) You have made no examination since?—I am constantly making examinations of the river in various parts, making soundings in various parts, and taking the depth of the mud, and so on.

5711. Can you give us any opinion as to whether there has been any increase in the accumulation since December 1878, down to the present time?—I think there is an increase always going on; I think it cannot be otherwise.

5712. (*Sir John Coode.*) Do you attribute that increase wholly and solely to the sewage?—I will not say wholly and solely, but I think the sewage contributes a very great share.

*Capt. J. Fitzgerald, R.N.*

5 Dec. 1882.

5713. (*Dr. de Chaumont.*) Have you observed an increase?—I have observed increases of mud on the foreshores, and I know that in certain parts of the river there is less water than there used to be, and I take it for granted, as there is such an enormous quantity of solid matter coming down the river, that it must help to form these banks and make the water shallower.

(*Mr. Bidder.*) I hope it will be remembered that as to the fact of accumulations in this part of the river there is no dispute at all.

The witness withdrew.

CAPTAIN CHARLES HENRY JAMES called in; examined by Mr. LUMLEY SMITH.

*Capt. C. H. James.*

5714. I believe you are the harbour master of the Thames Conservancy at Greenwich?—I am.

5715. I believe you have known the river all your life, have you not?—I have.

5716. And how long is that?—That is 67 years. I am 69 years old.

5717. I will ask you one or two questions about the early condition of the river. You went to sea in 1828, did you not?—Yes, in the latter part of 1828.

5718. You used, then, to drink the Thames water, I believe?—Yes.

5719. And you took it to sea with you?—Yes.

5720. What part of the river did you take it from then?—The first duty I had on board a ship was in the latter part of 1828, when I was put to see the men fill the water from alongside the hulk outside the East India Dock.

5721. It was taken from there and taken to sea in casks?—Yes.

5722. How long have you been harbour master at various parts of the river?—Since February 1840.

5723. In that year were you stationed at Gravesend?—I was.

5724. And your district extended, I think, up to the lower part of Woolwich?—It did.

5725. And were you constantly on the river?—I was constantly on the river between Gravesend and Woolwich for 11 years.

5726. Are you now in the service of the Thames Conservancy?—Yes.

5727. You are now harbour master at Greenwich?—Yes.

5728. What is Captain Fitzgerald?—Harbour master on the central station from Greenwich down to Greenhithe.

5729. (*Mr. Bidder.*) You are in the upper part of the river?—Yes, in the pools.

5730. (*Mr. Lumley Smith.*) From 1840, for 11 years, your district was from Gravesend to the lower part of Woolwich?—It was.

5731. During that time was the water good in that district?—Perfectly good and sweet.

5732. Was it drunk at any time of the tide?—You could drink it as far as Halfway Reach. You could have drunk it, I do not say we ever did; but it was perfectly drinkable at low water.

5733. That would be when fresh water was running down, I suppose?—Yes.

5734. In the year 1850 you came to Limehouse district, did you not?—In 1850 or 1851, I will not be quite certain which.

5735. Your district then extended from Greenwich up to London Bridge?—From Limehouse to London Bridge.

5736. At that time was the Thames water drunk?—Yes, it was.

5737. Where was it drunk?—It was drunk at Limehouse. A good many people used to drink it.

5738. There were pumps there, were there not?—Yes. Very shortly afterwards it ceased to be drunk; but it was drunk in 1851 when I was there.

5739. Do you remember where the whitebait used to be caught?—It used to be caught at the East India Dock entrance at Blackwall.

5740. Now, I believe, there is none to be met with there?—There is none to be met with in the river at all; they are obliged to go into the other river for it.

5741. You remember, do you not, the outfalls being opened at Barking and Crossness?—I do.

5742. Do you remember in what year that was in?—1863, 1864, 1865, and 1866.

5743. Since that time has there been any change in the character of the water?—Yes, it has got very foul.

5744. What parts, in your judgment, have become foul?—From London Bridge downwards, the whole of the river; and that is proved, I think, by the eel-schuyts, the eel vessels that used to lie at Erith; they are now driven away to Hole Haven, and they cannot even lie in the river there.

5745. You are speaking there, I presume, chiefly from hearsay, are you not?—No, I am speaking from knowledge, that they are driven away from Erith. They were driven away from Erith, I think, in 1869. They went down to Greenhithe then, and they were driven away from there in 1870. They went to Gravesend and lay there two years, I think; and now they are driven away down to Hole Haven.

5746. I believe from time to time when the water was very bad you have reported, have you not?—Yes.

5747. And you have made entries in your journal?—Yes.

5748. Did you do that generally with regard to the river, or only when it was very bad or very good?—Only when it was very bad.

5749. Have you your journals here?—They are here (*producing them*).

5750. In 1880 have you an entry on the 29th of July?—I cannot speak before that for the month of July, for I was absent.

5751. (*Mr. Bidder.*) Is this the first entry in any year?—I think it is. I was not ordered to do it before then.

5752. (*Mr. Lumley Smith.*) How came you to make these entries in the year 1880?—I was de ired by Captain Burstall, the secretary of the Conservancy, to make an entry of the state of the water.

5753. And in consequence of that you did it?—Yes.

5754. What is your entry on the 29th of July?—"Water in the river very black, and offensive to the "smell."

5755. What is your entry on the 30th of July?—"Water in the river very black and offensive."

5756. (*Mr. Bidder.*) Can you fix the place?—From Greenwich to London Bridge.

*Capt. C. H. James,*

5 Dec. 1882.

5757. (*Mr. Lumley Smith.*) How would these observations be taken? Did you go out to a particular spot, or were they taken as you were rowing up in the course of your duty?—In the course of my duty; as I was going up from Greenwich to London Bridge and back again.

5758. This is the result of your observation in that trip?—Yes.

5759. You are not able to specify any particular reach or anything of that sort?—The whole of the river from London Bridge to Greenwich.

5760. What is your entry on the 31st of July?—"The water very black and offensive in the creek as "well as in the river." That is in Deptford Creek. "To Deptford by train and visited and inspected the "creek;" that was Deptford Creek.

5761. What is your entry on the 1st of August?—"Water in the river very foul and offensive."

5762. What is your entry on the 2nd of August?—"Water in the river very black and offensive."

5763. What entry have you on the 3rd of August?—"Water in the river very much discoloured and "offensive."

5764. What entry have you on the 4th of August?—"Water in the river very foul and offensive."

5765. What is your entry on the 5th of August?—"Water very foul and offensive."

5766. What entry have you on the 6th of August?—"Water in river very foul and offensive."

5767. What is your entry on the 7th of August?—"Water very foul and offensive."

5768. What is your entry on the 8th of August?—"Water in the river very foul and offensive." That was confined to the forenoon.

5769. What is your entry on the 9th of August?—"The water in the river very foul and offensive."

5770. What is your entry on the 10th of August?—"Water in the river very foul and offensive."

5771. What entry have you on the 11th of August?—"Water in the river very foul and offensive."

5772. What is your entry on the 12th of August?—"Water in the river very foul and offensive."

5773. (*Mr. Bidder.*) There is not much originality about your entries. Captain Fitzgerald had a much more extensive vocabulary?—Very likely, but I do not see how it could be altered. It was very foul and offensive.

5774. (*Mr. Lumley Smith.*) The 13th and 14th are very much the same, are they not?—I do not think I have any entry on the 13th.

5775. What is your entry on the 15th of August?—"Water in the river very foul and offensive." I do not see what else I could say.

5776. What entry have you on the 16th of August?—"Water in river of a rather improved character."

5777. What is your entry on the 17th of August?—"Water in the river very foul and offensive."

5778. I think to the end of the month it is very much the same, is it not?—"River and creek very "foul and offensive" on the 20th.

5779. What entry have you on the 1st of September?—"Water in the river foul and offensive."

5780. Do you jump then to the 13th of September; have you any entries on the 2nd, and so on?—"Water foul" on the 2nd.

5781. I think it improves on the 14th of September, does it not; what is your entry on the 14th?—I do not think I have any. On the 15th I have this entry, "Water not so foul and offensive as it has been."

5782. Have you an entry on the 21st of September?—"Water very foul."

5783. Then I think you have no more entries that year. On July 5th, 1881, did the water get very bad again?—The entry on that date is this: "Water very "offensive at high water, and continued so until quite "half ebb."

5784. That is at high water between Greenwich and London Bridge?—Yes.

5785. What is your entry on the 6th of July?—"Water in the river less offensive."

5786. Then I think you have no entry until the 14th of July?—"The water in the river very dark and "discoloured, and very offensive towards high water "as far as Limehouse."

5787. When you say as far as Limehouse, would that be from Greenwich to Limehouse?—From Greenwich to Limehouse.

5788. What is your entry on the 15th of July?—"Water very foul and offensive at high water, until "half ebb or 8 p.m."

5789. The entries on the 16th and 17th, I think, are very much the same, are they not?—The entry on the 16th is, "Water very foul and offensive," and the entry on the 17th is "Water foul and offensive at high "water."

5790. What is your entry on the 18th of July?—"Water in the river very foul and offensive towards "high water or 6 a.m."

5791. What is your entry on the 19th of July?—"Water foul and offensive in the first and latter "parts."

5792. What does that mean?—That means that at 9 o'clock in the morning it was very foul and offensive, and the "latter parts" means before 8 o'clock at night.

5793. It means parts of the day, and not parts of your district?—Quite so.

5794. What entry have you on the 20th of July?—"Water foul and offensive at high water, 8 a.m. until "half ebb."

5795. What is your entry on the 21st of July?—"Water in the river very foul and discoloured towards "high water and until a quarter ebb, and very offen-"sive. High water at 9.50 a.m. The same at "night."

5796. On the 22nd of July I think it took a turn for the better?—"Water not so offensive as for days "past."

5797. What is your entry on the 23rd of July?—"Water in the river foul and very offensive near high "water and at the half ebb. High water at noon."

5798. I think there is no entry on the 24th of July. What is your entry on the 25th?—"Water less foul "and offensive."

5799. Then from the 26th to the 30th of July the entries are much the same, I think. Then on the 1st and 2nd of August what entries have you?—"Water "in the river very foul and offensive" on the 1st, and then "Water in river foul and offensive" on the 2nd.

5800. On the 3rd of August what entry have you?—"The water in the river not so foul or offensive as "it has been, but still offensive."

5801. Then you went away on leave?—I went away on the 4th of August.

5802. You live at Greenwich, do you not?—Yes.

5803. Are you near the river?—Close to it.

5804. Do you find anything disagreeable from the river?—Yes, I do.

5805. What do you find?—A very disagreeable smell. I always sleep with my window open as long as I can; that is, from about May till October; but I have frequently had to get up and shut it.

5806. Why?—The smell was so disagreeable.

5807. That you find you are obliged to do for your own comfort?—Yes; and I have frequently been made quite ill with it going up and coming down, so that I have not been able to eat my dinner when I have got home.

Cross-examined by Mr. Bidder.

5808. Your journey up and down is between Greenwich and London Bridge, is it not?—It is in general, but I have done the duty on the central station several times.

5809. But generally your journey is from Greenwich to London Bridge and back?—Yes, it is.

5810. I believe it is the fact that a very large number of people in the summer time take that water

journey for pleasure?—I daresay they do. It is more than I should do.

5811. Naturally, as it is your business, you would hardly go to the same place for your recreation. You have been on the river, and, as you say, acquainted with the river for a long time. You spoke of the time when the water used to be drinkable; is it not the fact that when Thames water in the olden days was taken on board ships and put into casks it always fermented or putrefied in the first instance?—Yes, it always did.

5812. They kept the bungs out of the casks to let the gases escape, did they not?—Yes; if you did not it would set on fire if you put a light to it.

5813. Do you say that the condition of the river in your district from Greenwich to London Bridge is worse than it used to be?—It is worse than it used to be before the year 1854.

5814. Then, if any gentleman has told the Commissioners that it is better in that part of the river than it used to be, he is saying what is contrary to the fact?—The general tone of the water is much better; but in the hot weather, or when there is very little water coming down the river, then it is very bad.

5815. Then your observation is, that generally the river is in a much better condition than it was in before the outfalls were made?—I do not say that; I say the water is sweeter.

5816. Sweeter than it was before the outfalls were opened?—Yes, all up here; that is to say, from London to Limehouse.

5817. Mr. Edmonds, a witness who was called before the Commission, says that the upper reaches of the river, that is to say, from London Bridge to Limehouse, have become purer, and that the lower reaches of the river have become fouler year by year?—That is just what I say.

5818. You agree with that so far?—I do. I mean by the upper reaches, from Limehouse to London Bridge.

5819. With regard to your journal observations, I think you were one of the witnesses that I had the pleasure of examining upon the last occasion, when you tried to father the mud banks on us?—I think the mud banks are caused by the sewage. I am certain of it. I said they would do so, and they do do so.

5820. You were one of the witnesses?—I was.

5821. And you were examined at about the same time as Captain Fitzgerald?—I do not know. I was examined.

5822. Then after that you had instructions, as I understand, from Captain Burstall to make notes of the condition of the river?—I do not know whether it was before or after; but I was ordered by Captain Burstall to do so, and I did so. It was no part of my duty to do so before. My duty is to regulate the ships, not to see about the water.

5823. I assume that you did it when you were told to do it; of course if any offensive matter comes to you from Barking and Crossness, it must pass through Captain Fitzgerald's district to get to you?—I suppose so.

5824. Can you explain to me how this happens; you begin your entries on the 29th of July?—I do not know when.

5825. Probably Captain Burstall had given you instructions about the 28th. Can you explain to me how it happens that at the time you begin your entries, the river being foul, I find Captain Fitzgerald recording that the river is getting better every day?—I do not care what Captain Fitzgerald says, I say my books are perfectly right.

5826. But you must have some respect for your colleague?—I have no respect for anybody who says anything contrary to what my books say.

5827. Is this a fair description of the state of the river on the 29th of July. "Water in the river rather "better to-day owing to the prevalence of strong "westerly winds"?—I do not know what Captain Fitzgerald says.

5828. Forget Captain Fitzgerald. I simply ask you whether this is a correct description of the river on that day, "Water in the river rather better to-day "owing to the prevalence of strong westerly winds"?

(*Chairman.*) He is speaking of a different part of the river. It is an excellent remark to make in a speech, but I do not know how it applies to the witness in the shape of a question.

5829. (*Mr. Bidder, to the witness.*) Is this a fair description of your part of the river?—If you can tell me the date I will tell you.

5830. The 29th of July 1880, the very day when you made your first record?—On the 29th of July I have this entry, "Strong west wind, with rain in "the middle part, lightning, thunder, and heavy rain."

5831. Is this a fair description of the river on that day, "Surface water fairly clean and free from smell"?—Certainly not in my district.

5832. Now I will go to the 30th of July. Is this a fair description of the river on that date, "Water in "river continues to improve, but the foreshore and "some of the landing-places clothed with sewage "mud"?—I cannot say what it had been before because I was absent until the 29th of July. I cannot say whether it had improved, because I cannot say what it had been before, and Captain Fitzgerald only says what it is in reference to what it had been.

5833. Now we have got to the 31st. Is this correct as describing the condition of the river on that day, "River water continues to improve"?—I do not know, "Water very black and offensive in the "creek as well as in the river." That is what I have got.

5834. You have no record of any improvement?—No.

5835. Now I will go to the 2nd of August. Is this a fair description of the condition of the river then, "River water moderately clear and free from "smell at high water"?—My entry is, "Water in "the river very black and offensive in the upper "district."

(*Chairman.*) I do not see the object of this cross-examination, because we have the two notes and we can compare the two.

(*Mr. Bidder.*) I do not think you have these passages, sir.

(*Sir John Coode.*) I understand that one witness is speaking with regard to one district and the other witness is speaking with regard to another district.

(*Chairman.*) If these entries have not been read, then Captain Fitzgerald ought to be called in again and cross-examined upon them.

(*Mr. Lumley Smith.*) I think you will find that they were all read. As I understand, that was the book from which Captain Fitzgerald was reading when he was examined.

(*Chairman.*) But as I understand Mr. Bidder he says that these passages were not read by Captain Fitzgerald.

(*Mr. Bidder.*) I think the course which you suggest is much more regular, and it will serve my purpose equally well. I have drawn the witness' attention to the passages and that is sufficient, I may be mistaken, but I think I am right in saying that those passages were not read; then I will pass from that.

(*Mr. Lumley Smith.*) If they are not in they shall be furnished to my learned friend, and he shall have an opportunity of seeing them.

(*Sir John Coode.*) If Mr. Bidder is not satisfied when he sees the print of the evidence perhaps he can re-call Captain Fitzgerald.

(*Mr. Bidder.*) I will just name the dates. August the 3rd, 4th, 5th, and 13th.

5836. (*To the witness.*) I take it that of late years your business has not taken you, as a rule, into the lower reaches of the river?—Not as a rule; I have been there several times.

5837. As regards the Dutch eel schuyts, your professional acquaintance with their place of anchorage must date from past years?—No, it does not; it dates till the time they left.

*Capt. C. H. James.*

5 Dec. 1882.

5838. You said that they anchored at Erith till 1869, I think. We have had some evidence here to show that they left Erith a good deal earlier; are you quite sure that you are right in your date?—Yes, I am quite sure that the last of the eel schuyts did not leave until 1869. Some of them may have left before, but not all.

5839. Then one other statement of yours rather startled me. You said that there are no whitebait in the river at all now, but that they have to go to "the other river"?—There are none at all.

5840. What is the river that they go to?—The Medway.

5841. Do you mean to say that no whitebait are caught in the Thames at all, practically?—No, not practically; or anything like what there used to be.

Examined by the Commission.

5842. (*Chairman.*) You say that the river between Greenwich and London Bridge is generally better than it used to be?—From the time that the sewers all came into the river, that was from 1851 or 1852. All the sewer outfalls, 170, or whatever the number was that used to pour into the river in 1864, were all taken down to this other place. It has improved the upper part of the river, except in very hot weather and except in very dry weather; and then the upper part of the river is just as bad as ever, or worse.

5843. You spoke of whitebait being formerly caught at Blackwall; did not that cease long before the outfalls were opened?—That ceased as early as 1851, and then they went down to Long Reach for them, and they have been driven away altogether now; they do not get them at all.

5844. (*Sir John Coode.*) You spoke of the river being generally foul and offensive between Greenwich and London Bridge; do your duties take you to London Bridge every day?—Every day.

5845. And you still think that the river at London Bridge is foul and offensive in the summer months?—Yes, in hot weather, and very offensive too.

5846. (*Mr. Bidder, through the Commission.*) Have you any entries in this present year?—No, none at all.

The witness withdrew.

Mr. William Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb., called in; examined by Mr. Balfour Browne.

*Mr. W. Collingridge. M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

5847. I think you are the Medical Officer of Health to the Port of London Sanitary Authority?—I am.

5848. When were you appointed to that office?—In May 1880.

5849. Whom did you succeed?—I succeeded Dr. Harry Leach, who died six months before.

5850. Have you, since your appointment as medical officer, been in the habit of spending much time upon the river during the last two years?—I spend a great deal of time upon the river.

5851. Where does your duty upon the river principally lie?—Principally between Westminster or Waterloo and Purfleet.

5852. Purfleet is just below Erith, is it not?—It is. Those are not the limits of the jurisdiction.

5853. But that is where you are principally occupied?—Quite so.

5854. And those are the parts of the river of which you have had the best opportunity of judging?—Quite so.

5855. Can you say generally what the condition of the river has been during these two years?—During the summer months, more particularly, the river water has been extremely bad. I notice that whenever we have continued hot weather, more than two or three days successively, the water becomes darker in colour, and we get this very offensive smell, that of course being always worse in the neighbourhood of the outfalls; and I also notice these black patches of sewage.

5856. Do you say that the black patches come with any particular state of the weather?—They always come in hot weather.

5857. And they are worse in the neighbourhood of the outfalls?—Yes, in the neighbourhood of the outfalls and above. I have not noticed them, to the same extent, below.

5858. The state of the river you say is very bad; it has been described here as foul, is it also of a dark colour?—Yes.

5859. Can you tell the Commission whether the condition of the river, so far as the eye and sense of smell are concerned, is exaggerated by agitation?—Very much so. You notice that particularly standing behind the paddles of a steamer; there you always notice it even when you do not get it in any other way, when there is really no smell from the water itself.

5860. One of the witnesses told the Commission to-day that occasionally you find the water pretty clear on the surface, but underneath of a much worse character; as far as your experience is concerned, is that true?—Yes; certainly.

5861. You say that it is always worse in dry weather?—Always.

5862. Can you tell the Commission whether it is after a short period of drought and heat that these conditions that you have been speaking of principally appear?—They begin generally, I have noticed, if we have two or three days hot weather. In the very few hot days that we had this year, I think on the third or fourth day after the hot weather, the colour of the water began to change.

5863. You have spoken of its being increased by the stirring up of the paddles, and also of the patches; is it your view that those patches come from below and spread over the surface?—I believe that the patches are caused by the influence of the tide, or some other influence bringing up the sewage mud from the bottom of the water.

5864. How would you describe the patches?—I should describe them as very slightly diluted sewage.

5865. How do you judge of that?—I have taken specimens of these black patches, and taken them to my office in bottles and examined them. They are very thick indeed; there is a very large amount of suspended matter, and the smell from it is horrible. A large quantity of the suspended matter is pure sewage, fæcal matter. These specimens have not been chemically examined.

5866. But you have no doubt of the correctness of your opinion that it is sewage matter?—I have no doubt whatever.

5867. Have you watched the stream as it flows out from the outfalls?—Frequently.

5868. Can that be traced for a considerable distance on the river?—At times. It depends very much upon the state of the weather and upon the direction of the wind.

5869. When it can be traced, what is the character of the stream upon the surface as seen by you?—It is a very dark smooth stream. You can see distinctly the difference between the colour of the stream of sewage and the colour of the river water; and you notice that particularly in cold windy weather, when the river water seems comparatively pure and of a brown colour. You see the two streams running side by side, the brown and the black.

5870. Is there anything clearly distinguishable in that black stream that marks it as being sewage?—Certainly. In the stream you have these small pieces of fæcal matter, which are small as a rule, but some-

times you come upon very large masses; you get matches, paper, and vegetable matter, and a large quantity of corks at times.

5871. Can you tell the Commission how far that stream, which you say is distinguishable from the water of the river, can be traced?—I have traced it downwards, well into Erith Bight.

5872. (*Chairman.*) From the outfalls?—From the outfalls.

5873. (*Mr. Bidder.*) That would be from Crossness, I suppose?—Yes.

5874. (*Mr. Balfour Browne.*) And you say that the colour of that stream contrasts completely with the colour of the water around it?—Yes, very strongly. Of course, as you follow it down, the difference becomes less marked; so that eventually you lose it altogether.

5875. Has the wind less effect upon that stream than it has upon the other water, or more?—It has less effect upon the surface of the water. You see that very well indeed, if you look across the river. When there is sufficient wind to ripple the surface of the river generally, the surface of the sewage stream is perfectly smooth; it has an oily appearance.

5876. (*Sir John Coode.*) To what do you attribute that smoothness?—Simply to the oily or greasy matter in the sewage.

5877. (*Mr. Balfour Browne.*) In fact, this is a great experiment of throwing oil upon the waters?—Exactly; it is a very good instance.

5878. Have you on several occasions watched, and have your deputies watched, the outflow from the outfalls, with the view of finding out how and when it flows?—It was watched.

5879. (*Mr. Bidder.*) Did you watch it?—I watched it during part of the time. I was present during the whole of the night, and I watched the two outfalls at intervals. During the time that I was absent from the outfalls my officers were there in the boat. I went backwards and forwards from one outfall to the other.

5880. (*Mr. Balfour Browne.*) And those officers have been called, I think, already?—They have been called, and have given evidence upon that point.

5881. What are their names?—Lewis and Spadaccini.

5882. One of those occasions on which you were personally present was the 30th of June 1882, I think?—Yes.

5883. Would you tell the Commission what you observed at 7.15 in the evening?—The sewage was running out.

(*Mr. Bidder.*) My learned friend may take it as admitted that there are occasions, though it is contrary to the general practice, when the sewage has been obliged to be let out before the flood.

(*Chairman.*) It may be taken shortly.

(*Witness.*) The 30th of June was one of these occasions.

5884. (*Mr. Balfour Browne.*) From your own personal observation, can you tell the Commission how many times you have seen this?—I have seen it a number of times, but I can only give you a few dates. I saw it on the 16th of last November.

5885. On the 28th of July?—The 28th of July was the date to which you referred when these inspectors were watching the outfalls. On the 30th of June I was down the river on the Conservancy steamer, and the outfall was running then. I think it was just about low water.

5886. You have yourself repeatedly seen the discharge taking place?—I have repeatedly.

5887. What I am referring to particularly is a discharge taking place either just before or on the flood?—Yes; on that date which I gave, viz., November 16th, the discharge was actually on the flood.

5888. Owing to its discharge on the flood, in what direction does it go?—Upwards, certainly, if discharged on the flood.

5889. The object of course of the restriction put upon the Metropolitan Board was that it should all be carried upon the tide going down?

(*Chairman.*) That is scarcely a question to put to the witness.

(*Mr. Balfour Browne, to the witness.*) You can, of course, if my learned friend wishes it, on all these occasions that you have mentioned, give the time of high water at London Bridge as compared with the time at which you saw the sewage flowing?

(*Mr. Bidder.*) It is a well-known fact that the board have already designed increased reservoirs, because there were occasions upon which the reservoirs were not large enough to hold the sewage.

5890. (*Mr. Balfour Browne, to the witness.*) Is it in your experience a rare occurrence that this takes place?—I think not.

5891. (*Chairman.*) You have noticed it on three occasions which you have mentioned, viz., the 16th of November, the 30th of June, and the 28th of July. Were there many more dates on which you noticed it?—Certainly there were more.

5892. Were there three more?—More than that. I must have seen it on at least a dozen occasions.

5893. (*Mr. Balfour Browne.*) Though you have observed it on other occasions, those are the only three days that you can give dates for?—Exactly.

5894. What is the highest point of the river at which you have seen this black discolouration, and the floating fæcal matter going up the Thames, as a distinct stream?—As a distinct stream I have traced it up to Blackwall.

5895. Of course it goes much higher, but you cannot trace it?—Certainly. You can trace actual fæcal matter much higher up, but not as a distinct stream.

5896. (*Chairman.*) When you say a "distinct stream," do you mean a continuous stream?—Not absolutely continuous, but sufficiently so for one to be able to follow it up in a boat.

5897. (*Mr. Balfour Browne.*) I think you have given the date of the 29th of June 1882?—I have not given that date.

5898. Do you remember an occasion when you traced it to Blackwall?—The occasion was during the summer before last, during 1881, and I think it was about the middle of July. I have no record.

5899. In your experience has the state of the river during the last summer been so bad as it was in the previous year, or the year before that?—The last years have been exceptional years. I think the worst state in which I ever saw the river was in 1880. I think it was distinctly worse then than in either this year or last year.

5900. Do you remember what the condition of the river was at the end of June in this year?—It was very bad indeed.

5901. Was there hot weather at that time?—Yes.

5902. However, you say that as far as your term of office has extended the worst period was in July 1880?—Yes, I think it was. There has been very little hot summer weather indeed in the last three years.

5903. Where was it worst in July 1880?—It was worse, of course, in the neighbourhood of the outfalls. After that it was worst at Woolwich, and below Woolwich and below the outfalls, about Jenningtree Point.

5904. Did you at that time think it necessary to report formally to the Conservators of the Thames upon the condition of the river?—I wrote to the Thames Conservancy.

5905. You have not, of course, got that letter, but you have a copy of it which you have supplied to Sir Thomas Nelson?—I have.

(*Mr. Bidder.*) We must have the original.

(*Chairman.*) There is not the slightest objection to having a copy put in if the parties agree to do so, but I object to having a verbal account of the contents of a paper.

(*Mr. Balfour Browne.*) I believe we are lucky enough, in this instance, to have the original, seeing

*Mr. W. Collingridge M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

5 Dec. 1882.

that Captain Fitzgerald, who is an officer of the Conservancy, has it in his possession.

(*Mr. Bidder.*) Of course the witness can give in evidence whatever he has stated in the letter?

(*Chairman.*) That is the material thing.

5906. (*Mr. Balfour Browne, to the witness.*) As a matter of fact, the condition of the river at that time, as detailed in this letter, was what you have been telling the Commission?—It was.

5907. But you thought it so important that you reported it to the Conservators?—I did.

5908. Can you tell the Commission what was the condition of the river in the summer of 1881?—The condition of the river was very much the same in 1881 as it had been in previous years. I do not think it was quite so bad (though there was very little difference) because the weather was not quite so hot, nor did the hot weather last so long.

5909. And you, again, called the attention of the Conservancy to the fact in a letter, which I will not put in?—I did.

5910. I believe on that occasion you also felt it your duty to urge upon the Port Sanitary Committee, of whom you are an officer, the necessity of taking some steps?—I did.

5911. And, I believe, it was after that date that they made the application to the Government which has resulted in this Commission?—Yes.

5912. It was after your report that they applied to the Government?—It was.

5913. I do not know whether you know, as a matter of fact, that they were advised that they had no power to interfere?

(*Chairman.*) Surely that is not material to us.

(*Mr. Balfour Browne.*) It happened, as a matter of fact, to be brought to his knowledge, but we can prove it otherwise.

(*To the witness.*) Apart from these questions of reporting and other matters, is it your view that there is extreme danger——

(*Chairman.*) That is rather putting his opinion into his mouth for him.

5914. (*To the witness.*) Have you any opinion about the state of the river being dangerous in any respect?—I have. I think it is decidedly dangerous. In my opinion it is impossible to pour sewage into a river to the extent to which it is poured in in the Thames without serious danger to health.

5915. (*Mr. Balfour Browne.*) Have you yourself at any time suffered any inconvenience from the state of the river?—I have frequently, in hot weather, been very seriously inconvenienced indeed.

5916. How does it manifest itself?—I have had distinct nausea, and in two or three cases I have had actual vomitting. I frequently get diarrhœa when I have been on the water in hot weather for any length of time.

5917. Can you, as a medical man, say that it is due to the state of the river that you suffer from these symptoms?—I think I can undoubtedly, because I only have these symptoms after I have been on the river in hot weather for any length of time, and I get rid of them by staying, as I am sometimes obliged to do, away from the river for three or four days.

5918. Do you know the mud which is deposited upon the banks, and which is exposed to the atmosphere at low water?—Yes.

5919. What is the character of that mud?—The mud generally is dark slimy black stuff, and has a peculiar gelatinous appearance.

5920. Where particularly do you notice that gelatinous appearance of the mud?—Particularly nearer to the outfalls.

5921. Are you acquainted with the factories and works which are upon the banks of the river in the neighbourhood of the outfalls?—I am.

5922. Do any of those give out offensive smells?—Yes, some of them undoubtedly do.

5923. Can you tell the Commission whether the smells given out by those factories are at all like that which you say comes from the river?—Not in the slightest. The smells given out by the factories are all distinct smells. It is possible in passing down the river to check off the factories as you come to them, provided that the wind is blowing in such a direction as to bring the smells across the river. It is impossible to mistake the smell of the factories for the smell of the sewage.

5924. Is it your duty as medical officer to present half yearly reports to the Port Sanitary Committee of the Corporation?—It is.

5925. When was your first report presented?—I have not the exact date, but it was a report for 1880. It was partly my own report, but the greater part of the report was made up from records. The report which was presented in December 1880 was for the year ending the 30th of June 1880.

5926. (*Chairman.*) You reported facts there which were not within your knowledge?—I did, giving the authority for them in the report.

5927. (*Mr. Bidder.*) That report was principally compiled, I understand, from your predecessor's record?—It was.

(*Mr. Balfour Browne.*) I see in that report you speak of a second and recent outbreak which commenced on September 23rd, 1879.

(*Mr. Bidder.*) That cannot be within his own knowledge.

(*Mr. Balfour Browne.*) We cannot call Dr. Leach, he having passed away, and anything that this gentleman got in his professional duty from Dr. Leach's memoranda or books would be evidence.

(*Mr. Bidder.*) Certainly it would not.

(*Chairman.*) These are matters of public notoriety. If you wanted to establish the fact that there was an outbreak of disease, you would find five hundred people who would be able to tell you that.

(*Mr. Balfour Browne.*) Dr. Leach's report is already in, I understand.

(*Mr. Bidder.*) It is not put in.

(*Chairman.*) What we want from the witness are facts within his own knowledge.

5928. (*Mr. Balfour Browne, to the witness.*) Referring to the report which was made in July 1880, and presented in December 1880, what part of it deals with your own work and your own observation as distinguished from that of your predecessor, Dr. Leach?—Certainly, a very small part of it. I think the only part of the report which is my own has no connexion with this question.

5929. Then January 1881 was the date of your next report, I think?—The next report is the report for the half year ending the 31st December 1880.

5930. So that it would be made in January of the next year?—Yes.

5931. That deals with your own observations, does it not?—It does.

(*Mr. Bidder.*) I certainly object to the witness putting in his reports. Ask him any questions as to facts which he states there and get them in evidence.

(*Chairman, to the witness.*) Looking at that report, are you prepared to state to us that all the facts that are stated there are correct to the best of your knowledge and belief?—I am.

*After some discussion, the witness put in the following extracts from his Reports, and his cross-examination was deferred, in order to give counsel for the Metropolitan Board of Works an opportunity of reading the extracts.*

## EXTRACTS FROM REPORT TO THE PORT SANITARY AUTHORITY FOR THE YEAR ENDING 30TH JUNE, 1880.

### Steam Ship Condor.

A report having been received on May 5th of an outbreak of disease on board the steamship "Condor," belonging to the General Steam Navigation Company, an inquiry was instituted as to the cause of this, and also as to the sanitary condition of the vessel. The outbreak had occurred during a voyage to Charente,

and on the passage home the captain had applied to the quarantine officer at the Motherbank.

Five seamen had been attacked suddenly with a febrile and prostrating malady, and one of them with a fatal result.

The outbreak seemed to have been one of typhoid fever, caused very probably by bad water taken on board during a previous voyage to Stettin.

The sanitary condition of the steamer itself was very good.

### School Ships.

In two only of the seven training ships, containing altogether between two or three thousand young subjects, were any cases of zymotic disease observed in the course of the half year, and the sanitary condition of most of these establishments remained very satisfactory during this period.

On January 23rd, a boy from the training ship "Shaftesbury," lying off Grays, was attacked with scarlet fever whilst under medical treatment in a house used as an infirmary.

Six days later another case appeared on board the ship, and after another interval of a few days a third case.

In the course of February three other cases occurred on board. In these latter cases the fever seems to have been of a very mild character, and its symptoms not very decided.

In the first three cases there were severe and well marked indications of a bad type of scarlet fever; of this small number one was fatal.

Active steps were taken by the captain-superintendent and the medical officer of the ship to prevent extension of the fever, and these were fortunately attended with such success, that what promised to become an outbreak of a very serious character was, in its early stage, most effectually controlled and stamped out.

In this instance considerable difficulty was at one time experienced by the authorities of the "Shaftesbury" in obtaining hospital accommodation on shore for the boys attacked by the fever.

As the ship infirmary in Grays could not (through the conditions under which it had been let) be used for the reception and treatment of cases of infectious disease, it was found necessary to send two of the patients to the Homerton Fever Hospital, but further accommodation here was refused on account of the "Shaftesbury" being placed without the district of the Metropolitan Asylums Board. Ultimately application was made to this authority for the use of the hospital ship "Rhin," to which, after your permission had been granted, the later and mild cases were sent for treatment by your medical officer Mr. Whitcombe.

In consideration of the constant risk of importation of scarlet fever into a school containing many young inmates, and the probability of this affection spreading rapidly and widely in spite of the most vigorous sanitary action, it is, I think, very desirable that every training ship should establish an outlying infirmary, either on the river or on shore, for the sole purpose of the separation and treatment of cases of infectious disease.

Notwithstanding the very favourable sanitary condition of the "Arethusa" training ship, lying off Greenhithe, several isolated cases of typhoid fever were, during the winter, sent from this institution to the Seamen's Hospital at Greenwich.

A full inquiry has been made into the origin of the fever in these instances, but without any satisfactory result.

On March 15th the Local Government Board published an important report of what was supposed to be enteric fever that occurred during October last on board the Reformatory Ship "Cornwall," lying off Purfleet.

As this outbreak, and also a previous one in 1875 of a somewhat similar character, occurred in the district of this authority, and had engaged the attention of your late medical officer, I propose to give here a brief review of the facts connected with the outbreaks in question.

In the second half-yearly report for 1875, your attention was directed by Mr. Harry Leach to the occurrence in September of that year of an extended, though not very fatal, outbreak of fever on board the "Cornwall"; of 258 persons resident in the ship, 120, or nearly 50 per cent., were attached, but, notwithstanding this very large number of cases, two only were fatal.

The epidemic persisted for several months, and did not decline until after the removal, in accordance with the instructions of your medical officer, of the crew to another vessel, and a change of locality from Purfleet to Gravesend.

The boys returned to the "Cornwall" in January 1876, certain structural alterations having been made in the ship with the view of improving its sanitary condition. From that time, up to the commencement of the recent outbreak, the health of all on board seems to have been very satisfactory.

Athough in this outbreak the symptoms in the majority of cases were very mild and obscure, and the mortality was remarkably low, no doubt seems to have been entertained as to the nature of the disease. In the fatal and severe cases the symptoms had evidently been of a "typhoid" character, and as they could not be referred to any other recognised morbid condition, the outbreak was consequently assumed to have been one of typhoid or enteric fever.

By those who subsequently made inquiries on this assumption as to the nature of the outbreak, no satisfactory results could be made out as to its origin. Mr. Leach could not, as stated in his Report, ascertain how or where the boy first attached took the disease, and the medical officer ordered by the Local Government Board in 1877 to make an inquiry was for various reasons unable to complete it.

Certain suggestions were made by Mr. Harry Leach as to the removal and disinfection of the ship, certain structural alterations, improvements in the supply, carriage, and storage of drinking water, which seemed to have been so effectual, that the vessel remained in a satisfactory sanitary condition for nearly four years.

A second and recent outbreak commenced on September 23rd, 1879, and lasted for 30 days, during which period 43, out of a crew of 262 boys and 15 officers, were placed on the sick list.

The majority of these cases, including all that were severe, were at once removed from the ship and treated in a temporary hospital, and 14 cases, most of them being very slight, were sent to the Seamen's Hospital.

In this, as in the previous outbreak, most of the cases were very obscure, and presented very mild symptoms, and in at least 15 instances it was quite clear that the patient suffered from little more than the effects of panic.

Not more than a score of the boys suffered from severe and well marked illness, and there was but one fatal case.

In most of these instances there could be no doubt that the symptoms resembled very much those of typhoid fever, and were not indicative of any other affection known in this country.

From this fact, and also from its similarity to the former outbreak, the nature of which has not been doubted, the second outbreak was also regarded as one of typhoid fever.

This view was based on what was believed to be clear and positive clinical evidence, and notwithstanding such difficulties as the extremely low mortality and the absence of the usual causes of such fever.

At the request of the Home Secretary a medical inquiry was in March last ordered by the Local Government Board. An exhaustive investigation was carried out by Mr. W. H. Power, who furnished a Report upon the subject, to which Report I would refer for further information.

*Mr. W. Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

## EXTRACTS FROM REPORT TO 31st DECEMBER, 1880.

### River.

The insanitary condition of the river during the summer has attracted the attention, not only of your officers, but also of the general public.

The water is at all times in a very unsatisfactory condition, and must remain so while such enormous quantities of sewage are thrown into it. During July it became very much worse than usual. Its colour, at all times bad, had become decidedly darker, and it gave a most intolerable smell. Though generally of a dark colour, it had still darker slate-coloured patches over which the odour was more intense. Samples taken from these slate-coloured patches proved them to consist simply of sewage more or less diluted.

Complaints were received from numerous and various sources, both afloat and on shore, and much anxiety was naturally felt lest, with the continuance of hot weather, serious consequences should ensue.

It became a very important point to determine the cause of this unusual pollution, and if possible to take some steps to remove the same.

There could be no doubt that a certain proportion of sewage was derived from the great metropolitan outfalls at Barking and Crossness.

This quantity would of course be increased if the sluices at these places were opened during the flow of the tide. This was asserted to have been the case, but although a watch was kept off these two stations for more than a week, both day and night, no definite proof could be obtained.

This, however, is but one of the very numerous causes of the fouling of the river. There are other very important ones.

Firstly, contamination from the large floating population of the river. This has been estimated at from 15,000 to 20,000 persons. Although much has been done to minimise this by improved arrangements, by providing proper closet accommodation, and by closing up all closets and heads as soon as vessels arrive, still there must always be a seriously and unavoidably large amount of sewage passed into the river from this source alone.

Again, the numerous drains and closets which empty themselves into the river in most of the riparian districts within the jurisdiction of the port.

The number of these is very large. In a special report on the subject in September last I gave the total number as 384.

These, under the River Pollution Act, this authority has power to deal with, and at an early date I intend to bring the subject under the notice of your honourable committee, with a view to taking active steps to close and divert them.

### School Ships.

With the exception of the "Arethusa" and "Cornwall," the health of the school ships has been fairly good.

On the "Warspite" there has been one case of scarlatina and one of typhoid fever.

The typhoid fever occurred at the time when the state of the river was at its worst, and though it is impossible to attribute it to this, still without doubt this in itself was quite sufficient to account for it.

During September there was a renewal of the epidemic of typhoid fever on board the "Arethusa."

This vessel lies off Greenhithe. During the early part of the year several cases had occurred. The disease was of a mild type, and there were no deaths, but still there appeared to be no doubt as to the nature of the outbreak.

| | | | |
|---|---|---|---|
| The 1st case was on | - - | January | 19th |
| 2nd „ | - - | „ | 20th |
| 3rd „ | - - | „ | 23rd |
| 4th „ | - - | February | 7th |
| 5th „ | - - | „ | 12th |
| The 6th case was on | - - | March | 26th |
| 7th „ | - - | April | 5th |
| 8th „ | - - | „ | 23rd |
| 9th „ | - - | May | 7th |
| 10th „ | - - | „ | 23rd |
| 11th „ | - - | August | 31st |
| 12th and 13th „ | - - | September | 6th |
| 14th „ | - - | „ | 16th |
| 16th and 17th „ | - - | „ | 18th |

There were thus 17 cases in all, with a decided break in the series during June, July, and August.

It was obvious from this remarkable succession of cases that there were some unfavourable circumstances affecting the ship, and it became a matter of the utmost importance to make a thorough and complete investigation.

The diet scale is extremely good, no salt meat or pork being issued; the provisions appear to be all of a first-class character.

The drinking water is of excellent quality, derived from a spring in the chalk some distance from the river.

Moreover, the food and water are exactly the same as supplied to the "Chichester," which lies but a very short distance above the "Arethusa," and on which no cases have occurred.

The latrine accommodation is good, and always kept in a clean and proper condition.

It seemed, therefore, that the cause must lie in the ship itself.

After a thorough examination the only weak point that I could attach importance to was the ballasting of the ship.

The ballast is shingle, and it seems to me to be objectionable in several ways.

In the first place, it is very light, and therefore takes up a large space, which would otherwise be available for purposes of ventilation.

Secondly, it is difficult to move, and hence the occasional shifting, and exposure of all parts of the vessel to the air cannot be carried out. This I consider a very important point. Then, again, damp may exist and decomposition occur, the more dangerous, inasmuch as it is hidden from sight.

There is one other possible cause of danger to the health of the ship. It is moored opposite a small creek into which several houses drain.

As, however, there had been no cases of enteric fever on shore, this particular outbreak cannot be assigned to this cause.

With the sanction of your Committee, I advised the authorities to remove the shingle ballast and substitute for it pig iron.

This, however, on account of the great cost (800*l.* or 900*l.*) they were unwilling to do, but have carried out sundry other improvements which I had suggested.

It has since been decided to use the "Chichester" for a time as a drill ship only, and to berth her crew, 70 in number on board the "Arethusa" which will thus have her complement raised to 270.

### "Cornwall."

During November an epidemic of typhoid fever prevailed on board the "Cornwall," which is stationed off Purfleet.

Several previous epidemics have attacked the same vessel. In my last report I gave a brief resumé of these several epidemics, and stated all that was known as to their probable cause and nature.

The last outbreak has been of a more decided character.

Twenty-one have suffered, and several of them severely, but happily only one death has occurred.

I carefully watched as far as possible those who were attacked, and came to the conclusion that they were undoubted cases of typhoid or enteric fever, which opinion was confirmed by Dr. de Brent, the medical officer in charge of the ship.

I have thoroughly examined the vessel and can find in her no sanitary defect or possible cause for the fever.

The drinking water is of excellent quality, and is brought off from the shore by a flexible hose.

Samples taken at the commencement of the epidemic gave very satisfactory results on analysis, while others, taken since, betray a large amount of organic material. This was satisfactorily accounted for by the careless manner in which the samples had been collected; fresh analyses are at the present time being made.*

As a measure of precaution, pending the elucidation of this important point, Captain Morrell, R.N., has wisely had all water boiled before issue.

Those boys infected were at once removed to the infirmary, a suitable iron erection about a mile off, where they were tended by Dr. de Brent, assisted by an efficient staff; very strict sanitary precautions were observed, and the outbreak speedily arrested. A post-mortem was held on the boy who died, which proved beyond a doubt that the epidemic was one of typhoid fever.

It seems that with this unfortunate history of repeated outbreaks there must be something radically wrong, and I am inclined to attribute much of the blame to the position of the vessel. She lies off Purfleet in a bight, and the stream during the ebb, after striking the opposite point, sets directly into this bay. At ebb the current carries down the great volume of sewage from the metropolitan outfalls with it. This can be seen occasionally as a dark line on the water, while at all times evidences of sewage can be found in the mud on the foreshore; moreover, it has been proved by analysis that during the ebb the water on the north shore at this point contains a very much larger amount of ammonia in combination than that on the south shore.

It seems only necessary then to have typhoid fever in London, and then as a direct consequence the germs are carried through our sewers, through the metropolitan outfalls, straight into the river, and thus naturally find their way to Purfleet.

It has been fairly well established that the poison of typhoid fever is practically innocuous at the time it leaves the body, but that about the third day after decomposition has set in it becomes highly dangerous. Obviously this would be about the stage which the germs carried to Purfleet would have reached. Whatever danger there might be to the health of the vessel from the state of the river water would be greatly increased by the practice of washing decks with it. This objectionable plan has now been entirely given up.

Under these circumstances, it is hardly, I think, a matter of much surprise if outbreaks should from time to time occur.

Our legislature, in sanctioning the pollution of our great water highway by the discharge of enormous quantities of sewage, must bear the responsibility of conveying disease therewith.

If the constant outpouring of sewage continues, it will become, sooner or later, a grave question whether the Thames will any longer be a proper or safe river for stationing our training ships.

## EXTRACTS FROM REPORT TO THE 30TH JUNE, 1881.

### The River.

The condition of the water still continues, as it must while the sewage of the metropolis is poured into it, a source of great anxiety to all concerned with the health of those engaged thereon.

Public attention is being gradually drawn to the serious error committed in throwing such valuable material into the great water highway, and a strong feeling is growing up, that sooner or later arrangements must be made more consistent with common sense and the present state of sanitary science.

At present, however, these are protected by law, and your authority has hitherto contented itself with the minor causes of pollution. During February your Committee sanctioned the addressing of a letter to those Riparian Authorities who allowed sewage to flow into the Thames from their district, calling upon them to discontinue the same. (*See* Appendix L.)

This letter produced, as was expected, very important changes in the sewage outfalls of the Upland Riparian Authorities.

Chiswick has constructed a large main sewer, and diverted from the river a large number of outfalls at Strand-on-the-Green.

In Twickenham several outfalls have been diverted, and we are informed by the authorities that in a few months all will have disappeared.

In Chelsea the vestry issued notices to all owners of property where these nuisances existed calling upon them to divert forthwith.

St. George's, Hanover, diverted the only foul outfall it possessed.

The City, also, has removed its only one at London Bridge.

Poplar.—The Board of Works have diverted a certain number. With regard to the others, they object that the outfalls are on premises where there is no sewer within 200 feet, and that, therefore, they have no power to compel connexion.

Woolwich.—The one closet emptying into the river in this district has been pulled down.

Battersea.—Two foul outfalls have been diverted and notices served on five owners of property where others exist. As no answers were received from Isleworth, Fulham, Westminster, Whitechapel, Limehouse, West Ham, Barnes, St. Saviour's, Rotherhithe, Greenwich, and Charlton, it was considered advisable by your Honourable Committee that a second communication should be sent to them. This was done on April 11th (*see* Appendix L.) with the following results.

Fulham reported that in several cases the owners of premises draining into the river have had proceedings taken against them and the outfalls closed, and that action against others will follow.

Westminster.—The necessary works are in hand.

Whitechapel.—The only foul outfall has been diverted.

Limehouse.—Notices have been served upon the owners of property where the outfalls have not already been diverted.

St. Saviour's.—The clerk reported that all the foul outfalls in this district have been intercepted or stopped, with the exception of one discharging surface water, and which is innoxious.

It will thus be seen that there is a decided tendency on the part of these various authorities to comply with the requirements of the Port Sanitary Committee, and though, doubtless, some of these reports are not strictly carried out, still it is certain that by the action of your Honourable Committee much pollution of the river has been prevented.

St. Olave's.—The medical officer wrote, "that as at "present advised the Board does not consider it has "any power." As the course of this authority seemed perfectly clear the correspondence was handed to the City solicitor to advise and report thereon.

On the 12th May his report was received, giving as his opinion that sanitary authority in this Act is defined as, "any urban or rural sanitary acting in the "execution of the Public Health Act, 1875," and that, therefore, Port Sanitary Authorities are not included in the term sanitary authority to whom the enforcement of the provisions of the Act is given by the 8th section. (*See* Appendix L.)

In view then of this opinion it was clear that no further proceedings could be taken. It must, however, be a matter of great satisfaction that so much has been accomplished without the assistance of legal proceedings.

### The Training Ships.

The health of the training ships during the past six months has been exceptionally good, not one case of infectious disease having occurred on any of them.

* Since this Report has been printed, the results of these analyses have been obtained, and show the water to be above all suspicion of having caused the disease.

*Mr. W. Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

5 Dec. 1882.

This is remarkable, as the number of boys on all these vessels averages about 1,750, and these all at a time of life most susceptible to the influence of zymotic disease.

During a very heavy gale in January last the "Shaftesbury" was carried away by the force of the wind and ice and thrown upon the shore. Happily no serious injury was sustained by either staff or boys, and owing to the excellent discipline no confusion occurred.

The vessel was towed off by tugs, and after a short stay at Greenhithe was taken into the Royal Albert Docks, where she was repaired.

## APPENDIX L.

Port Sanitary Offices,
Greenwich, S.E.,
14th February 1881.

To the Medical Officer of Health
to the Sanitary Authority of the District of

SIR,

I AM instructed by the Port of London Sanitary Authority to call your attention to the enclosed list of foul outfalls into the River Thames within your district.

The existence of these outfalls being contrary to the provisions of the Rivers Pollution Act (39 & 40 Vict. c. 75.), and being one of the principal causes of the insanitary condition of the river, I require you to divert the same forthwith, or to use them only for storm or clean water.

I am, &c.
(Signed) WILLIAM COLLINGRIDGE,
Medical Officer of Health,
Port of London.

Port Sanitary Offices,
Greenwich, S.E.,
11th April 1881.

To the Medical Officer of Health
for the District of

SIR,

ON the 14th of February last, by the direction of the Port of London Sanitary Authority, I wrote to you calling attention to the foul outfalls into the river, and requesting diversion of the same. Up to the present date only a formal acknowledgment has been received. Will you kindly let me know what action the Local Board is taking in the matter.

I am, &c.
(Signed) W. COLLINGRIDGE,
Medical Officer of Health,
Port of London.

## APPENDIX M.

(Copy.)

To the Worshipful the Port of London Sanitary Committee.

GENTLEMEN,

I HAVE considered the papers referred to me by your order of the 5th April, relating to certain foul outfalls in the district of St. Olave, Southwark, going into the River Thames, and I am of opinion that the Port Sanitary Authority have no jurisdiction to interfere in the matter.

The Statute 39 & 40 Vict. c. 75. (being the "Rivers "Prevention Pollution Act, 1876"), defines Sanitary Authority to mean in that Act "any Urban or Rural "Sanitary Authority acting in the execution of the "Public Health Act, 1875," and it is clear therefore that Port Sanitary Authorities are not included under the term "Sanitary Authority," to whom the enforcement of the provisions of the Act is given by the 8th section.

I have, &c.
(Signed) T. J. NELSON,
City Solicitor.

Guildhall,
May 12th, 1881.

## REPORT PRESENTED 15TH DECEMBER 1881.

Port Sanitary Offices,
Greenwich, S.E.,
December 8th, 1881.

To the Chairman and Members of the Port Sanitary Committee.

MR. CHAIRMAN AND GENTLEMEN,

I BEG herewith to hand you, in a rough form, the results of the investigation of the sub-committee appointed to inquire into the condition of the river, and the analyses of samples of water taken by them. These analyses I have arranged in a tabular form in such a manner that they can be easily compared with one another, and also with one or two other well-known waters.

The condition of the Thames generally is naturally very different at this season from that in the summer.

This obviously depends upon several causes; in the first place the sewage itself contains a much larger amount of storm water; secondly, the river receives more water from the upland districts; and lastly, the effect of continued high temperature materially assists in the decomposition of organic matter.

Your Committee were of necessity then prepared to find the water in a better state than if the investigation had been carried on during the summer. The whole of the river has been inspected—the lower part, viz., from Gravesend to Woolwich, on November 23rd, and the upper part, as high as Teddington Lock, on December 3rd. Barking Creek was specially inspected on December 20th, and Bow Creek on December 12th.

On each occasion samples of water were taken at various points, and these submitted to careful analysis by your medical officer.

Some of them were also handed to Professor Wanklyn, with the object of obtaining an independent and therefore a confirmatory result.

The details of the analysis were found to agree fairly closely, with one exception, viz., the estimation of the total solids where there is a wide divergence. This is explained by the fact that Professor Wanklyn reduced these at a low red heat, while your medical officer employed a temperature under 212° Fahr.

The sample taken at Teddington shows the state in which the river water exists at the commencement of your jurisdiction.

It contains a very small amount of solids and chlorine, and a fairly small quantity of ammonia, and is described by Professor Wanklyn as "impure, but "impurity probably of vegetable origin."

Thus at London Bridge, although the total solid residue is small (24·6 grains according to Professor Wanklyn, and 38 grains in a gallon according to your medical officer), still there is a large proportion of organic matter, and the water is clearly charged with sewage.

As the water is traced down it is found to gradually increase in impurity as it receives the sewage of riparian districts.

At the metropolitan outfalls at Barking and Crossness this impurity becomes much more marked.

The worst specimen examined was the one taken at Barking on 23rd November when the tide was running down, and which is reported to contain about one fifth of its volume of sewage. The Crossness, although very bad, is a great improvement on this.

Lower down still, owing to the enormous dilution, and the influence of oxidation, the river again becomes much less foul, and a sample taken off Tilbury is said to be "practically uncontaminated with sewage." The series of results is an extremely interesting and instructive one, and show clearly the very great influence the outfalls have in polluting the stream.

It is an unfortunate point, however, that this effect has been so much exaggerated, inasmuch as the mere exaggeration weakens any argument in support of this view.

*Mr. W. Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

5 Dec. 1882.

Whatever may be the results of analyses, and the inspection of the river at this season, there can, however, be no doubt with those who are in the habit of travelling on the Thames during the hot weather, as to the extremely foul state of its waters, and there is abundant evidence to show that at any rate some part (and that by no means a small one) of its offensiveness is due to the discharge of the sewage by the Metropolitan Board of Works.

And it is the more important to state this inasmuch as the amount of sewage is constantly increasing, as shown by the following Table :—

SEWAGE DISCHARGED at OUTFALLS, 1869 to 1878 inclusive.

| Rainfall. | Year. | Gallons per Year. | |
|---|---|---|---|
| | | Crossness. | Barking. |
| 27·93 | 1869 | 17,574,292,274 | 12,793,513,197 |
| 18·89 | 1870 | 16,678,226,567 | 14,633,751,920 |
| 26·44 | 1871 | 18,497,165,385 | 20,112,448,713 |
| 32·88 | 1872 | 22,281,418,356 | 23,137,747,554 |
| 24·31 | 1873 | 21,878,839,124 | 22,680,778,594 |
| 24·12 | 1874 | 20,544,185,537 | 22,610,777,770 |
| 29·28 | 1875 | 23,505,775,239 | 26,955,262,659 |
| 28·90 | 1876 | 22,370,124,831 | 27,751,403,034 |
| 29·26 | 1877 | 26,008,009,706 | 29,995,714,676 |
| 29·26 | 1878 | 27,317,822,594 | 30,177,765,147 |
| 271·27 | 10 years | 216,655,859,613 | 230,849,163,264 |
| Average per year. 27·1 | | 21,665,585,961 | 23,084,916,326 |
| Average per diem. — | | 59,357,769 | 63,246,346 |
| | | Together 122,604,115 | |

Showing an increase of about 14 per cent. in 10 years, with a practically uniform rainfall.

There can be no question, if one may judge by the literature of the subject, that the condition of the Thames has much improved since the Metropolitan Board of Works have carried the sewage down to Barking and Crossness, but the fact still remains that our mode of disposal by throwing it in our great water highway and polluting it to an enormous extent, is a disgrace to our vaunted civilisation.

But beyond the Board of Works is the question of the sewage of other riparian authorities.

The position of the Port Sanitary Committee with regard to this matter has at length been clearly defined. Legal opinion having been obtained, it is decided that they have no authority under the Rivers Pollution Act.

There can be no question about this decision, and the situation is certainly an anomalous one.

The Thames, the largest and certainly most important of all our rivers, is to remain the only exception to the law which rightly considers pollution of a stream as a serious offence.

True, other bodies have power to a certain extent, but these are so limited and hampered as to be practically inoperative where most needed.

Later on this must become a question for serious consideration.

In order to show the extent of this riparian pollution, I append a list of foul outfalls.

Inasmuch as a large sum is to be shortly expended in constructing a new reservoir at the outfalls, it would certainly seem advisable that an inquiry by the Home Secretary should be urged upon him by this Committee before these works be undertaken.

Many riparian authorities and inhabitants are prepared to assist in any such proceeding, and abundant evidence is forthcoming as to the existence of a great and offensive nuisance.

I have, &c.

(Signed) WILLIAM COLLINGRIDGE,
M.B., S. Sc. Cert. Camb.,
Medical Officer of Health,
Port of London.

* The solids were dried at a temperature bordering upon a low red heat.

William Collingridge, M.B., S. Sc. Cert. Camb.,
Medical Officer of Health, Port of London.

Remarks by Professor Wanklyn on analysis of above samples :—

No. 1 is impure, impurity probably of vegetable origin.

No. 8 is very impure, being apparently charged with sewage.

No. 27 is mixed sea and river water, and is practically uncontaminated with sewage,

Nos. 20, 15, and 13 are also mixtures of sea and river water contaminated with sewage, 15 more than 20, and 13 rather less so.

No. 15 is very largely contaminated, and contains about one fifth of its volume of sewage.

J. Alfred Wanklyn,
Laboratory,
7, Westminster Chambers.

## EXTRACTS FROM REPORT TO 31st DECEMBER 1881.*

The number of foul cargoes dealt with according to their nature is, however, somewhat high. These consist chiefly of loads of manure and other refuse, and while in the interests of trade they must be allowed to pass to and fro on the river, it is the province of your officers to endeavour, as much as practicable, to minimise the nuisance arising therefrom.

### The State of the River.

The condition of the water of the Thames, always bad, of necessity is far worse in the summer than in the winter.

Naturally, as the population of London increases the amount of sewage becomes larger, and therefore whatever nuisance exists now must tend to be augmented every year.

That this is a nuisance denied by many persons can have no bearing on the actual facts.

During the first week in July the temperature was unusually high, and as any one accustomed to the river could have prophesied, its condition became exceedingly foul.

The water was of dark colour, and the smell therefrom intolerable. Every person who had business upon the river or its banks was unfortunately only too well aware of this. Moved by this abominable and disgraceful state of things, your Committee appointed a sub-committee to inquire into the matter.

This sub-committee investigated the subject, and a report with analyses, &c. has been already circulated, and is appended hereto.

But I would submit that this is not a matter for delicate chemical analyses, but rather one which any person possessed of ordinary sense of sight and smell is perfectly competent to give an opinion upon.

Fresh unmistakable fæces float upon the surface of our great river, and certainly this must be considered by every one to be a disgrace to the nation.

Public opinion and public indignation are at length being roused, and several very influential riparian authorities are prepared to second the efforts of the Corporation, and urge upon the Home Secretary those powers with which he is entrusted by Act of Parliament.

To a petition which was presented during August upwards of 13,000 signatures were appended, and these all of persons actually connected with the river.

The Port Sanitary Authority has done all in its power to prevent pollution. Many closets and foul outfalls have been closed or diverted by its action, but unhappily it has been decided to have no power under the Rivers Pollution Act, 1876, the only Act which could really strengthen its hand.

One part to which attention has been more particularly called is Limehouse Creek. Here a nuisance was found to exist, caused by the drifting of foul material floating, by the bad condition of the river mud, and also to some extent by the presence of closets and other foul outfalls.

On communicating with the medical officer of health of the Limehouse district, Dr. G. A. Rogers, I was informed that the Board had decided to make a clean sweep of all foul outfalls into the river, and that a new sewer had been constructed for this purpose. A large number have been already diverted, and the remainder will disappear as soon as their existence has been proved by your officers.

This is a great step in the right direction, for there can be no question that if all the foul outfalls from districts above Barking and Crossness were diverted, the state of the river would be to a certain extent improved.

But, unhappily, there would then still remain the outfalls of the Metropolitan Boards, undoubtedly the principal offenders.

### Other Infectious Diseases.

Considering the number of vessels which constantly enter the port, and the extremely unsanitary condition of many of the ports from whence they come, it is a matter for great congratulation that so few cases of infectious disease should be discovered.

On the 12th July a case of remittent fever was removed from the "Poonah" to the Seamen's Hospital.

On October 1st information was received of the existence of typhoid fever on the "Alsatia," which was coming up the river.

She was accordingly met as she entered the docks, and the patient at once removed to hospital.

This early notification arose from the prompt action of the Customs officials at Gravesend, who report all cases immediately they come under their notice.

This is of inestimable value to your authority, inasmuch as it completely obviates the necessity of having officers on duty at Gravesend to board every vessel, a proceeding which would only be necessary if we were threatened with an invasion of some epidemic such as cholera or plague.

### School Ships.

The health of boys on the various training ships in the river has been extremely satisfactory, there having been almost complete immunity from infectious disease.

During October two cases of scarlet fever occurred on the School Board Ship "Shaftesbury."

They were at once isolated and sent on board the "Rhin." One or two suspected cases were also immediately sent on shore, and by these prompt measures any further spread was prevented.

The vessel was at the time increasing her complement of boys, and new boys were being sent straight from their homes to the ship. It seems highly probable that in this way infection was conveyed to the ship, a source of danger which might be easily avoided by causing all new arrivals to perform "quarantine" of inspection," for ten days or a fortnight, at some building set apart for that purpose on shore.

## EXTRACTS FROM REPORT PRESENTED 5th OCTOBER 1882.

### Training Ships.

The general health of the boys on the training ships in the river has been remarkably good. In January a case of scarlet fever occurred on board the "Cornwall," for which no obvious cause could be ascertained.

About the same time, too, appeared a solitary case of measles on the same ship. The usual strict precautions as to immediate isolation, medical inspection of boys, and fumigation, were promptly carried out, and the disease disappeared, the health of the ship continuing perfect until the 12th of April, when another boy was attacked.

Here again it seemed impossible to trace with any degree of certainty the source of the infection. About a month ago a third, and happily the final case occurred, which, in all probability, must have arisen from the second.

* Date of Report 4th January 1882.

5 Dec. 1882.

### The River.

The continued representations of your Committee, and the public attention drawn to the highly polluted state of the river, have induced Her Majesty's Government to appoint a Royal Commission "To inquire "into, and report upon the system under which sewage "is discharged into the Thames by the Metropolitan "Board of Works; whether any evil effects result "therefrom, and, in that case, what measures can be "applied for remedying or preventing the same." This Commission has already commenced its sittings, and has taken a large amount of evidence bearing upon the question.

With a view to obtaining definite information as to the opinions of those living or having business upon the river, as to whether any nuisance existed, a circular was printed, and sent to the principal shipowners, brokers, agents, and merchants, who would be likely to have any personal knowledge of the river. *See* Appendix K. A large proportion of those addressed replied, and, as might have been expected, were almost unanimous in their expression of opinion that a serious nuisance was caused by the outflow of sewage.

It is, however, right to state that, owing to the exceptionally low temperature during the early part of the summer, and the large amount of rainfall, there has been less nuisance than is usual during the hot months of the year. During the last week of June the water again, however, assumed what may be called its summer condition; the colour became distinctly darker, and a faint sickly smell was clearly distinguished.

While attention is naturally drawn to the principal sources of sewage contamination by the outfalls at Barking and Crossness, attempts have been made with success to induce other sanitary authorities to discontinue discharging their quota into the river. In the Limehouse district alone no less than 12 foul outfalls have been recently removed, and the Local Board have decided to serve notices compelling diversion on those owners who still continue to pollute the river.

A communication has been received from the Whitechapel Board of Works, stating that in compliance with the request of the Port Sanitary Authority the last foul outfall into the river had been diverted. Thus leaving one more clean district.

The Local Board of St. Saviour's also having examined their district, and proved the accuracy of the list of foul outfalls presented by your medical officer, have pledged themselves to remove the same with the least possible delay.

These three districts show a most important advance during the half year, and such clearing up will prove most valuable in discriminating between the great sources of pollution and the smaller ones, and in indicating how exceedingly small the latter are by comparison.

Port of London Sanitary Offices,
Greenwich, S.E.,
March 15th, 1882.

Sir,

I am instructed by the Port Sanitary Committee of the Corporation of London to ask you to kindly furnish them with any evidence you may be able to give as to the pollution of the River Thames by sewage.

The chief points on which information is sought are:—

(i.) As to whether, in your opinion, any such nuisance exists.

(ii.) In what parts of the river and at what times is such nuisance most marked.

(iii.) Any evidence as to its effects on health of those engaged on or near the river.

Such information, if precise, and accompanied by names and addresses of the persons responsible for it, will be most valuable, and cannot fail to be of great public service in the event of any inquiry being held on the subject.

I am, &c.

(Signed) William Collingridge,
Medical Officer of Health,
Port of London.

Mr. Thomas Long called in; examined by Mr. Lumley Smith.

*Mr. T. Long.*

5933. I believe you are a waterman on board the "Conservator," which is in the service of the Thames Conservancy?—Yes.

5934. Have you been much on the Thames?—Yes, all my life nearly.

5935. Have you ever found that being on the Thames in any way affected your comfort or your health?—Yes, several times.

5936. Will you tell me when you remember that it affected your health?—In July 1880, one morning we were under weigh between 3 o'clock and half-past, and the water was very bad that morning; in fact we all felt sick. It affected everybody on board the boat.

5937. Amongst the rest of the people did it affect you?—Yes.

5938. Were you actually sick, or did you merely feel sick?—I felt sick. I had a nasty heaving, but I could not bring anything off my chest.

5939. What time of the day was it?—About 4 o'clock in the morning.

5940. Would that be when you were first starting?—Yes.

5941. Whereabouts was your ship?—At East Greenwich then.

5942. Had you known that to happen on other occasions before?—Yes, several times I felt as if I could be sick through the stench of the water.

5943. Was there anything in your health apart from the stench of the water that would account for your feeling in this way?—No, not the least. I always enjoy good health as a rule.

5944. Then you say that from the stench of the water you have felt yourself qualmish?—Yes, qualmish.

5945. That was in July in 1880; the river was pretty bad then, was it?—Yes, very bad; the worst, I think, I have known it.

5946. Did you notice what it looked like?—You could see lumps of stuff rise from the bed of the river, and then they would break open, and a fearful stench came from them when they broke open; all black mud stuff.

5947. Did you see them come up?—You could see them come up.

5948. You could see them come to the surface?—Yes.

5949. And then they break up, and this nasty smell comes from them?—Yes.

5950. I believe you were sent by Captain Fitzgerald in August 1881, to take some samples of water for him, were you not?—Yes.

5951. Who went with you?—George Lamerton, another waterman.

5952. I believe you went to the southern and northern outfalls?—Yes.

5953. Have you anything to fix the dates?—Yes.

5954. First of all did you report to Captain Fitzgerald each morning after you had been down there?—Yes.

5955. You went at different times of the day, did you not?—Mostly at night tides.

5956. And then you reported in the morning?—Yes.

5957. Did you take any notes at all?—Yes, just rough notes.

5958. What was the first day that you went?—The 17th of August 1881, I went to the southern outfall.

5959. Will you just read your note?

5960. (*Mr. Michael.*) Is that the note you took at the time?—No, not on the paper; I took it in a book.

5961. Where is the book?—I have only taken the rough note.

5962. (*Chairman.*) Have you got your book?—Yes (*producing a book, and handing it to Mr. Michael*).

5963. (*Mr. Michael.*) This was all written at the same time, was it not?—Every day that we went down it was written.

5964. (*Chairman.*) What did you find?—On the 17th of August we went to the southern outfall and took a sample of the water at high water, 7.20 p.m.

5965. (*Mr. Lumley Smith.*) Have you any note of what the sample was like?—The sample was very clear.

(*Mr. Michael.*) There is not a word in your book about the sample being clear. (*The book was handed to the witness.*)

5966. (*Mr. Lumley Smith.*) Read your note of the 17th?—"On the 17th we went to the southern out-"fall and took a sample of the water there at high "water at 7.20 p.m.," and the sample was clear, I have got it all here except "the sample was clear."

5967. Where do you get your note that on that day the sample was clear?—Here it is (*handing a paper to the learned counsel*); that is the rough note that I took in black lead pencil, then I wrote it down in my book afterwards.

5968. (*Sir John Coode.*) Is that rough paper the note that you made at the time?—Yes, that one I made in black lead pencil, and then I wrote it down in ink in the book afterwards.

5969. *Mr. Lumley Smith.*) This note on the 17th of July is on a piece of paper on which I see is written in pencil "S.O." What does "S.O." stand for?—That is southern outfall.

5970. Then there is the word "clear"?—Yes.

5971. That is all the entry for the 17th, but you have a fuller entry in your book, "Went to southern "outfall and took a sample," and you give the time?—Yes.

5972. On this piece of paper you have not got the time?—No.

5973. Where do you get your entry about the time?—I took the time from high water.

5974. And that was put in the next morning?—Yes.

(*Chairman.*) I think it would clear up the matter if we got a little more accurately the history of this paper.

5975. (*Mr. Lumley Smith, to the witness.*) In the boat you write on this piece of paper?—Yes.

5976. And I see your note of the 17th of July is "S. O. clear," that means "southern outfall, sample clear"?—Yes.

5977. When did you write in your book the entry which says that it was high water at 7.20?—After I had taken all the rough notes.

5978. (*Chairman.*) But how long after?—As soon as we had orders not to go any more to the outfalls I wrote it down in my book.

5979. The same day?—No, not the same day.

5980. How many days after?—We were doing it for five or six nights, I think.

5981. Then it was five or six nights after you first wrote on that paper that you put it into your book?—Yes.

5982. (*Mr. Lumley Smith.*) In the book you put "High water"?—Yes.

5983. Were they all taken at high water?—At the southern outfall they were.

5984. On the 17th at high water your sample is clear?—Yes.

5985. Then on the 18th at the southern outfall again it is again clear?—Yes.

5986. And that is at high water?—It is at high water.

5987. What did you do on the 19th?—On the 19th we went to the northern outfall and took a sample at 7.15; the sample was very thick, black almost.

5988. Do you know at what time it was high water on that day?—Yes, it was high water at 9.46 at London Bridge, that would be about 9.20 down there.

5989. You allow 26 minutes?—Yes.

5990. Then that would be before high water?—Yes, it would be two hours before high water.

5991. Were you able to see whether the sewage was escaping; is that a thing that you can actually see when you are in a boat?—Yes; you can see it coming out through the sluices.

5992. Can you do so at high water, or near high water?—Yes. This was a long time before high water; you could see it coming from the sluices, and it washed our boat away from the sluices.

5993. On this occasion, when you took your sample at 7.15, and you say it was thick, that was about two hours before high water?—Yes.

5994. Were you able to tell whether the sewage was escaping or not?—Oh, yes.

5995. On the 20th, your entry is "southern outfall, "sample clear"; is that at high water?—Yes.

5996. Your entry on the 21st is "northern outfall, "letting out," what does that mean?—I took a sample at 9.30.

5997. Your note here is "northern outfall, letting "out, took sample 9.30"; what do you mean by "letting out"?—Letting the sewage out.

5998. Then you made a note that the sewage was being let out at 9.30?—Yes.

5999. Do you know at what time it was high water on that day?—Yes, 12 o'clock at night, that would be about 11.35 there.

6000. The sewage was going out there at night about two hours before high water?—Yes.

6001. Your entry on the 22nd is, "Southern out-"fall, took sample at 12." Does that mean 12 o'clock?—Yes.

6002. "Clear"?—Yes.

6003. When was it high water on that day?—12.43 that night; that would be the next morning.

6004. "23rd N. O. letting out"; does that mean letting out the sewage?—Yes.

6005. "11;" does that mean 11 o'clock?—Yes.

6006. "Thick"?—It was very thick.

6007. When was it high water then?—At 1.43.

6008. There, again, the sewage was being let out on the flood?—Yes.

6009. "24th, at home;" "25th and 26th northern "outfall, took sample at 1.30 and 2.45." I suppose that entry was made after the second?—No, it was high water at 2.45; we took the sample at 1.30.

6010. "26th, northern outfall, took sample clear; "high water 3.47"?—Yes.

6011. And that is all, I think?—Yes, that was the last night.

6012. Is Lamerton here to-day?—He is here.

Cross-examined by Mr. Michael.

6013. What did you do with those samples which you had taken?—We gave them to Captain Fitzgerald.

6014. What were the samples taken in?—They were taken in bottles.

6015. How far from the surface of the water were they taken?—They were taken on the surface; we just put the bottle underneath the water.

6016. How large were the bottles?—About pint-and-a-half bottles, I should think.

6017. How many samples did you take altogether; did you take more than one at any particular time?—Only one at each time.

6018. How many times altogether?—There were six or seven of them, I am not sure which; there was

*Mr. T. Long.*

5 Dec. 1882.

one at each place. Each night that we went we took a sample, whether it was clear or thick.

6019. Was there a stopper to the bottle or a cork?—A cork.

6020. How long afterwards did you give it to Captain Fitzgerald?—The first night when we found it so thick we took it up to Captain Fitzgerald's house there and then; it was so thick and it stank so much.

6021. Did you give it to him?—Yes.

6022. How near was it to the outfalls that you took this matter that was thick and smelt badly?—We were not more than 30 or 40 feet away from the sluices.

6023. Do you know where the lip or apron is over which the sewage falls into the river?—At the northern outfall it comes out through arches.

6024. How near to them did you take the samples?—About 30 or 40 feet away.

6025. And how near were you at the southern outfall?—At the southern outfall we were right over the lip.

6026. So that you took the sewage as it came really out of the outfall?—Yes.

6027. You were not surprised to find it thick, I suppose?—No.

6028. It was absolutely the sewage that you took?—Yes.

6029. And the sewage had had hardly any opportunity to mix with the water?—Of course, when they let it out after high water it would have more chance of mixing with the water than if it were let out before.

6030. But you took it immediately as it came out at the outfall?—Yes; at the outfall.

6031. On all occasions?—Yes.

6032. For how many hours a day on an average are you on the river?—Ten hours a day on an average.

6033. Every day?—Yes.

6034. You do not seem to suffer very much?—Not always.

6035. Are there any other smells except the smell from the sewage that trouble you on the river?—The smells from the factories.

6036. Are they better or worse than the smell from the river?—Better.

6037. They never make you sick?—No.

6038. There are guano works, for instance?—I pass them every day, but you do not feel any ill effects from them.

6039. Does the smell from the river always make you feel sick?—In hot weather.

6040. And at 4 o'clock in the morning?—Yes.

6041. How many times can you recall in the whole of your life when you have felt sick?—I should say eight or nine times.

6042. And how many years have you been 10 hours a day on the river?—I have been in the Conservators' employment three years and six months.

6043. Before that what did you do?—I was serving my time on the water.

6044. You were on the river then?—Yes.

6045. What were you doing before when you were on the river?—Lightering.

6046. In barges?—Yes.

6047. Do they sometimes bring rather offensive stuff down the river?—Manure.

6048. Did that ever make you sick?—Never.

6049. You could be in the barge then with the manure for many hours and never be sick?—Yes, you could be in the barge with the manure and you would not smell it so much as if you were out of the barge, away from it.

6050. Then you have never experienced anything disagreeable from being with the manure in a barge?—No, not the least.

6051. It escaped away from you?—Yes.

6052. And none of these bad smells have ever affected you at all?—No.

6053. Merely the river?—Only the river, that is all I can put it down to.

Re-examined by Mr. Lumley Smith.

6054. My learned friend has asked you about your having taken these samples at the very outfall, if the sluices were shut down and no sewage was escaping, and it was high water or within a couple of hours of high water, you would get river water would you not?—Yes.

6055. By getting thick water you could see that the sewage was escaping?—Yes, and it pushed the boat away from the sluices.

Examined by the Commission.

6056. (*Chairman.*) But were not the sluices covered with water?—No, they were not covered, because the first time we went down the foreman of the outfall came out on the top of the sluices to speak to us.

6057. I was under the impression that the sluices were covered with water?—Not at the northern outfall.

6058. (*Sir John Coode.*) In answer to a question put by myself, a witness told us that these sluices were covered at two hours flood, you say they are not?—No, they are not.

(*Mr. Michael.*) This witness absolutely took the sewage out of the outfalls into his boat.

(*Mr. Lumley Smith.*) At a time when it ought not to have been discharged.

(*Mr. Michael.*) That is a matter which we will discuss afterwards.

(*Witness.*) The foreman belonging to the northern outfall came down on the top of the sluices on the night when we took it out and spoke to us in the boat.

6059. (*Chairman.*) And at that time you could see the sewage falling into the river?—Yes, coming into the river through the arches.

6060. It was actually falling into the water?—It runs into the water, there is no fall, it is all on a level where the bottom of the arches is. The arches come down underneath the brickwork, and the foreman came down on the top of the arches to speak to us.

6061. (*Sir John Coode.*) And you say that that was within two hours of high water?—It was quite two hours before high water.

6062. (*Chairman.*) And the arch was not covered then?—It was not covered then.

6063. (*Dr. Stevenson.*) At what time of the tide is the arch completely covered?—At three parts flood the arches would be covered.

The witness withdrew.

Mr. George Lamerton called in; and examined by Mr. Lumley Smith.

*Mr. G. Lamerton.*

6064. I believe you are a waterman on board the "Conservator"?—Yes.

6065. And, I believe, by direction of Captain Fitzgerald you went with Long to the outfalls to take some samples?—I did.

6066. Did you make notes of the times at which you went or of the samples which you took?—Yes.

6067. Will you give me your notes. (*The witness handed his notes to the learned counsel.*)

6068. (*Chairman.*) Did you and Long make your notes together?—Yes.

6069. (*Mr. Lumley Smith.*) You only took one sample between you?—That is all.

(*Mr. Michael.*) If he says it is the same note and the same sample I will not trouble him.

6070. (*Mr. Lumley Smith, to the witness.*) Do you remember being there on the 19th when the sewers were discharging when you took your sample?—Yes.

6071. Were you able to see that the sewage was coming out?—Yes; the man stood upon the top of the archway at the time, and the sluices were open, and I could see it running out. It washed the boat away.

6072. The arches at Barking at high tide are quite covered, are they not?—Yes.

6073. Are you able to tell how soon they are covered when the tide flows?—I should say at about half flood.

(*Mr. Michael.*) I think this witness is very nearly correct. I would not pledge myself to a few minutes, but I believe in about 2½ hours the arches would be covered; and that would be, as he says, about half flood.

*Mr. G. Lamerton.*

5 Dec. 1882.

Cross-examined by Mr. Michael.

6074. At the time that you took the sample the arches were not covered?—No.

6075. How far were they covered; how much could you see of the arches; could you see the crown of the arches?—Yes, half way down the arches.

6076. How long have you been on the river?—I have been at work on the river now for 17 years.

6077. How many hours a day do you live on the river?—Sometimes it is from 6 or 8 o'clock in the morning till 6 or 7 o'clock at night; sometimes all night.

6078. How long have you been on the river spending the whole of your time on the river?—About 12 years.

6079. What aged man are you?—I am 28.

6080. How many days on an average in a year are you laid up and unable to work?—I have not been laid up through it, but I have been very queer with the smell of the water.

6081. Are there any other smells on the river besides the smell from the water?—There is a factory down below.

6082. One?—There is one factory, I know, that smells at times.

6083. Is that a pleasant smell?—Not at all.

6084. Does that make you sick at all?—No, it does not make me sick, but it is a smell that you could not stand long.

The witness withdrew.

Adjourned to to-morrow at half-past 12 o'clock.

# ELEVENTH DAY.

## Wednesday, 6th December 1882.

PRESENT:

Sir P. BENSON MAXWELL in the Chair.

Sir John Coode, Mem. Inst. C.E.
Colonel C. B. Ewart, C.B., R.E.
Professor A. W. Williamson, F.R.S.

François de Chaumont, Esq., M.D., F.R.S.
Thomas Stevenson, Esq., M.D.
James Abernethy, Esq., F.R.S.E., Mem. Inst. C.E.

William Pole, Esq., F.R.S., *Secretary.*

Mr. William Turnidge called in; examined by Mr. Lumley Smith.

6085. You are a waterman on the "Conservator" steamer, I believe?—Yes.

6086. How long have you been one of the crew of the "Conservator"?—Going on for four years.

6087. Does the "Conservator" cruize up and down?—Yes.

6088. What is its ordinary duty?—Its duty is to see that the navigation of the river is kept clear.

6089. Are you on board night and day?—At times I am on board at nights.

6090. Is that when you have the night watches?—Yes.

6091. Is the steamer at moorings at night?—Yes, at night.

6092. Are they at any regular fixed spot?—Yes.

6093. Where is that?—At Charlton.

6094. Have you ever found the river offensive when you have been on board the "Conservator"?—Very much indeed at times.

6095. Have you ever found it interfere with your comfort or with your health?—Yes.

6096. In what way?—I have felt very sick indeed at times.

6097. Did that extend to your being actually sick, or were you merely sickish?—I have never brought anything up at any time, but I have felt very bad indeed, and on one occasion I was obliged to give over altogether, I was absent from work.

6098. Do you remember when that occasion was when you had to give over?—On the 26th of July 1880.

6099. To what do you attribute your illness then?—To the sewage water.

6100. You had not been drinking it, I suppose?—No.

6101. My learned friend, Mr. Bidder, suggests to me that I should ask you what you had been drinking. Was there anything, so far as you know, that could account for your illness, except this unpleasant smell from the river?—No, nothing whatever.

6102. Do you generally have good health?—Very good indeed.

6103. When did you find the river worst?—In 1880 I think it was much worse than at any other time.

*Mr. W. Turnidge.*

6th Dec. 1882.

Cross-examined by Mr. Michael.

*Mr. W. Turnidge.*

6 Dec. 1882.

6104. In 1880 the weather was very hot, and very dry, was it not?—Very warm at times.

6105. And it was in July of that year that you noticed that it was much worse than at any other time?—Yes.

6106. What were you doing at the time when you say you were obliged to leave your duty?—I was on watch the night previous, and we were obliged to get under weigh from our moorings at 3 o'clock in the morning to go to Greenwich. That was on the 26th, and that was when the sickness came over me.

6107. At what o'clock was it?—At 3 in the morning.

6108. How many hours do you usually spend on an average on the river every day?—From 10 hours and upwards.

6109. How old are you?—32 years.

6110. How long have you been on the river?—Going on for four years.

6111. But before that time where were you?—I was a fisherman.

6112. Did you fish in the river Thames?—At times, and at times I have been away to sea.

6113. You think that you were ill on this occasion on account of the smell from the river?—Yes.

6114. Do you think it was from the river itself?—Yes.

6115. Do you smell anything on the banks of the river?—No, I have not noticed anything.

6116. You do not smell anything from the works on the banks of the river?—There are a few smells, but nothing that affects me.

6117. Is the smell that you complain of in the water more powerful than the smell from the factories on the banks of the river?—Yes.

6118. And that is the thing which made you sick on this occasion at 3 o'clock in the morning?—Yes; I was ill throughout the day; I was unable to do any work.

6119. But that is the only time when you have been obliged to leave your work?—Yes.

6120. Where were your moorings on the day when you left at 3 o'clock and went up to Greenwich?—At Charlton. We left our moorings at Charlton.

Examined by the Commission.

6120*a*. (*Chairman.*) You only left your work once; did you ever feel sick except that once?—Yes, on several occasions.

6121. More than three times altogether?—At various times we have felt sick in the course of the warm weather. We have complained about it amongst ourselves on several occasions.

6122. But how often have you felt this inconvenience which you speak of?—I cannot say how many times, because I never made a note to that effect.

6123. But am I near the mark when I say three times?—A great many more times than that.

6124. (*Colonel Ewart.*) Had you to go to a medical man on account of it?—No, I was persuaded by Mr. Young to go to the hospital two or three times throughout the day, but I told him I thought I should feel better throughout the day.

6125. (*Sir John Coode.*) How long did you lie up?—I was absent from duty throughout that day, and for two or three days following I felt very queer, but I was able to do a little work on board the ship. My appetite fell very much indeed throughout the week.

The witness withdrew.

Mr. George Young called in; examined by Mr. Lumley Smith.

*Mr. G. Young.*

6126. You are, I believe, the master of the "Conservator"?—Yes.

6127. That is the steamer which takes the Conservancy officers about?—Yes.

6128. How long have you been the master of the "Conservator"?—Two years.

6129. How long have you been in the service of the Conservancy?—18 years.

6130. How long have you known the river?—For 30 years I have been constantly employed on it.

6131. I think, before you were in the service of the Conservancy you were a collier's pilot from Gravesend to London?—Yes.

6132. And you have known the river well for how many years?—Pretty well for 30 years.

6133. I will ask you first one or two general questions. Have you found any change in the character of the water since you have known the river?—Yes, very great changes indeed.

6134. You remember the outfalls being opened in 1864, do you not?—Yes, the northern one.

6135. And the other was opened a little later, I believe?—Yes.

6136. What was the character of the river at that time; in London the water was bad, I believe?—Yes, very bad indeed at that time.

6137. About how far down did the bad water go before the sewage was diverted to Barking and Crossness?—Down to about Bugsby and Woolwich. I have filled water for drinking purposes on board of the colliers in Gallions Reach at low water; in fact, that was a thing that was general.

6138. Was it general to drink the water?—To dip the water in Gallion's at low water for the ship's use.

6139. Then I suppose that was pretty good. What was it like up at Greenwich in those days?—It was not so clear at Greenwich, it was rather bad at Greenwich.

6140. Gallions is above the outfall, is it not?—Yes, it is in the same reach.

6141. What were Barking and Halfway Reaches like in those days?—They were comparatively clear, but of course the water is brackish down there; you would not drink that water.

6142. But when you come to Gallions Reach it has ceased to be brackish, and at low water you were able to drink it?—Yes.

6143. Since the outfalls have been opened have you noticed any change in the water in those reaches?—Yes.

6144. What do you find now?—Nothing but a mass of sewage.

6145. How far up do you find that the water is affected by the sewage?—It works its way, as far as I can see, up as far as Greenwich.

6146. Where is your ship moored as a rule?—At Charlton, off the upper part of the Royal Dockyard, Woolwich.

6147. You cruise about, I suppose, in the river at different places?—Between Greenhithe and Greenwich.

6148. Have you seen any change take place in the habits of the fishing vessels?—Yes.

(*Mr. Bidder.*) Is it necessary to go through that story about the fishing vessels again? We have had it five dozen times.

6149. (*Mr. Lumley-Smith to the witness.*) After the outfalls were opened did any change take place in the places where fish were caught?—Not for some four or five years.

6150. For some four or five years there was no change?—Not a great change.

6151. Where used the fish to be caught at that time?—I have seen them caught in Greenwich Bight, Bugsby, North Gallions, Long Reach, and so on.

6152. Does any fishing go on now in those reaches? No.

6153. I believe you have seen fish caught at Charlton lately, have you not?—Yes.

6154. How have they been caught?—By children on the banks, with their hands.

6155. Were they fish that seemed sick?—Yes, that is how they came to catch them. When they are brought down the river by these heavy rains, as soon as they touch this polluted water, of course the fish become sickly and weakened, and the children catch them with their hands alongshore.

6156. They survive the journey through London, and then they get so sickly at Charlton that they can be caught by hand?—Yes, I saw them catching them, and I saw the state the fish were in.

6157. I believe it is no part of your duty to take notes of the state of the river, is it?—It is not.

6158. But have you on occasions been instructed by Captain Fitzgerald to take notes?—During this past year I have; but I have made notes previously to that when the water was in such a state that it was not fit for any human being to live upon it.

6159. (*Sir John Coode.*) What was the particular part of the river where these fish were caught?—They were caught at Charlton beach, that is, between Siemens's electric factory and the ballast wharf.

6160. Have you seen the same sort of thing in any other part of the river?—No, only just there.

6161. Then your remark applies to that part of the river only?—Yes, in regard to the fish.

6162. (*Mr. Lumley-Smith.*) You mean in regard to catching the fish with their hands?—Yes.

6163. Is that where your ship was moored?—She was moored some quarter of a mile below that, but I was up there on duty, and I saw that.

6164. You have told us that you did take some notes in 1880, when it was very bad?—Yes, very bad indeed.

6165. You have your note, have you not, for the 26th of July 1880?—Yes (*producing a book*).

6166. (*Chairman.*) Is this book a log, or diary, or what?—It is the vessel's log.

6167. (*Mr. Lumley-Smith.*) Will you read your note on the 26th of July?—"Steam at 3 a.m. Pro- "ceeded from Charlton to blocks at Greenwich to "examine a portion of the vessel's bottom. While "there, the crew were employed in cleaning the "bottom, the sewage water having turned both "Jestey's composition, also the black paint, quite "brown."

6168. (*Mr. Bidder.*) What is Jestey's composition?—It is applied to prevent corrosion.

6169. (*Chairman.*) You keep the log yourself?—Yes.

6170. (*Mr. Lumley-Smith.*) Have you another paragraph in your entry?—Yes; "Steam from blocks "at Greenwich, arrived at moorings at Charlton at "4.30 p.m. Could not clean cabins, &c., on account "of the filthy sewage water at Charlton."

6171. What is Jestey's composition; is it a kind of paint?—It is a kind of paint to prevent corrosion.

6172. You say that the sewage water had turned this Jetsey's composition and the black paint brown?—Yes.

6173. Are you familiar with Jestey's composition and with black paint?—I have used it on this vessel only for two years.

6174. You say that it was the sewage that had turned it brown; what is your reason for saying that?—I imagine it by its turning its colour when it was quite clean only a day or two before; and on that morning more especially, when the water was, I think, about the worst I have ever seen, I noticed the vessel to be quite brown.

6175. It is not an affair of months; it is soon done. I understood you to say that it was done in a day or two?—The vessel was perfectly clean only a few days before.

6176. I see you make a note there that you could not clean the cabin on account of the filthy water; were you in the habit of using the river water for cleaning the cabin?—Yes.

6177. You have another entry on the 10th of September later on in the autumn; will you read as much of that as refers to the river?—Yes. "Crew "employed in stoning the deck, but could not finish "them until late in the evening on account of so "much sewage floating about." That is at Charlton.

6178. Will you explain why the sewage which was floating about should prevent your stoning the decks; what is the process of stoning the decks?—When they are scrubbed and they get a little rough, they rub a stone over them to brighten them up a bit.

6179. Why would the water outside prevent your doing that?—Because it prevents their sluicing them to wash the stuff off. The water was not fit for it. It was high water at about 4 o'clock on that day, and I had to wait until the tide had gone down past us and allow the sewage to get past the vessel, which made it, as I have remarked here, the evening before they could finish.

6180. Do I rightly understand you that at high water at Charlton, which is considerably above the outfalls, there was so much sewage floating about that you could not use the water for cleaning your decks?—Yes.

6181. You have another entry, I think, on the 22nd of September?—Yes.

6182. What is that entry?—"Crew employed in "various jobs about the vessel, the water being in "such a bad state of sewage that not until afternoon "could the vessel be washed down."

6183. That again is at Charlton?—It is.

6184. I believe that in July and August 1881 you made a few observations; was that by direction of Captain Fitzgerald?—Not in 1881.

6185. Then in 1881 you did it on your own account?—Yes.

6186. Will you give us the entry which you have on the 15th of July 1881?—"The river in such a bad "state of sewage, could not wash decks in forenoon."

6187. Where would that be?—At Charlton.

6188. Do you know at what time it was high tide that day?—4 o'clock in the afternoon.

6189. Then in the forenoon it would be rather low water, would it not?—Yes.

6190. What is your entry on the 18th of July?—"Anchored vessel off Greenhithe to wash decks, &c., "in consequence of the filthy state of the river at "Charlton through sewage."

6191. Would you in the ordinary course wash your decks at Charlton at your moorings?—Yes.

6192. On this occasion you went to Greenhithe?—Yes.

6193. Have you any entry of the time of the tide when this took place?—When we washed the decks it was about 1 o'clock in the day. The tide flowed at 6 o'clock at Charlton on that day, so that it would be low water time or the young flood at Greenhithe.

6194. (*Mr. Bidder.*) At what o'clock did you leave Charlton?—At 10 o'clock in the morning.

6195. (*Mr. Lumley-Smith.*) That would be on the ebb then?—We wash the decks on the young flood. On the ebb tide it would not be so well.

6196. But when you left Charlton, when the water was so dirty, what sort of tide would that be?—That would be about half ebb, a little better than half ebb.

6197. (*Mr. Bidder.*) And you got to Greenhithe at 1 o'clock?—I do not say what time we got there, because we called at several places, as we went along.

6198. (*Mr. Lumley-Smith.*) Will you read your entry on the 19th of July?—"River in a filthy state "of sewage, and not prudent to wet decks with it."

6199. That is at Charlton again?—Yes.

6200. Will you read your entry on the 20th?—"River in very bad state of sewage. Crew employed

*Mr. G. Young.*

6 Dec. 1882.

"conveying clean water from the shore to clean "cabins and vessel's outside with."

6201. That would also be at Charlton?—Yes.

6202. Then your men went ashore to get clean water?—Yes.

6203. What is your entry on the 21st of July?—"River in a filthy state of sewage, more especially "between Barking and Jenningtree Point."

6204. Have you an entry of the time of the tide on that occasion when it was so bad between Barking and Jenningtree Point?—I did not note that.

6205. What is your entry for the 22nd of July?—"Crew employed cleaning the vessel with water from "the shore, the river water not being fit for use."

6206. Where was that?—At Charlton.

6207. What is your entry on the 23rd of July?—"Crew employed conveying water from the shore to "clean vessel with. The river, although much clearer, "it is only on the surface, for I found the sewage to "be within 12 inches of the surface, and the stench "from the same being very bad."

6208. I think you have nothing more in that month, but you have an entry on the 2nd of August?—Yes, "Made vessel fast to a buoy in St. Clement's Reach "while washing decks, &c., through the river at "Charlton being in such a filthy state of sewage."

6209. Where is St. Clement's Reach?—Between Greenhithe and Grays.

6210. I think you have another entry on the 5th of September?—"River from Barking to Rainham in a "filthy state of sewage."

6211. Where is Rainham?—Rainham is considerably below Barking, the next town before you come to Erith.

6212. I think in 1882 you have some half dozen entries. There is one on the 17th of March 1882?—Yes. "Left Erith at 4.30 p.m. Between Erith "ballast wharf and Crossness the river in a filthy "state of sewage, the stench from same being very "bad."

6213. When was it high tide that day?—It was high tide at noon.

6214. At Erith?—At Charlton.

6215. And this would be about four hours after high tide?—Yes.

6216. That would be at a time when the outfalls were at work, I presume?—Yes, they would be running out on the ebb tide.

6217. Are you able to see the flow as it comes out; does it make any distinct track upon the river?—Yes, at times.

6218. I see that entry of yours speaks of the river; are you able to tell whether you were in the track of the sewage, or whether it pervaded the river generally?—It appeared to be right across the river there.

6219. Your next entry is on the 25th of March?—Yes. "In consequence of the river being in such a "filthy state of sewage, have not been able to clean "the vessel with the river water the whole of the "week."

6220. Where would that be?—At Charlton.

6221. What entry have you on the 6th of April?—"Crew employed conveying water from the shore for "the purpose of cleaning the vessel, owing to the "filthy state of the river water."

6222. Where would that be?—That is at Charlton.

6223. At what time of the tide?—That would be at low-water time, and on the early flood.

6224. You have an entry on the 30th of June, have you not?—Yes. "At 9 a.m. this morning the "river water at Charlton at about two hours flood "was in a stinking state of sewage, very offensive."

6225. That was a hot time, was it not?—Yes, that was this year.

6226. What is your entry on the 28th of July?—"The river in a very bad state of sewage from "about half way down Long Reach south shore to "Crossness."

6227. Have you any entry on the 2nd of October?—"At Charlton the river in a filthy state of sewage. "It appeared to be rising from the bottom of the "river, and caused very offensive smell. Unable to "clean vessel in consequence."

6228. What do you mean by "appearing to rise from the bottom of the river"; in what form does it come up?—It appeared as though it were fermenting, and rising up in small patches about the size round of an inkstand; and then it burst out, and spread round larger than a good size plate; and the smell from it became very bad. I can only describe it as though all the bed of the river was in a state of fermentation.

6229. In October it would not be such very hot weather?—No.

Cross-examined by Mr. Bidder.

6230. You have been for about two years master of the steamer, I understand?—Yes.

6231. Had you instructions to make notes in your log book about the river?—No.

6232. Are you quite sure, because we know that Captain Fitzgerald had instructions from the Conservators?—Yes, he may have had.

6233. But you are quite sure that you had none?—I am quite sure of that.

6234. I believe you have been constantly employed during the last two or three years in going about the river for the purpose of taking observations of the sewage, and of the mud, and for the purpose of taking samples, and so on?—No.

6235. For two years?—Occasionally, not so long ago as that. Last year I think was about the first of it.

6236. (*Chairman.*) You have been employed to take samples for about two years?—Hardly that. There is the first account of it, and that is in 1881.

6237. (*Mr. Bidder.*) You have been engaged in taking various gentlemen down to view the river for the purpose of the Sewage Inquiry, have you not?—Yes.

6238. It has been a matter of constant discussion on board the vessel, I suppose?—Yes.

6239. You have referred to 1880, 1881, and 1882; do you say that this year is as bad or not so bad as 1881?—Not so bad.

6240. What do you say comparing 1880 and 1881?—1880 was the worst.

6241. And 1881 next?—1881 was of course very bad during the warm weather.

6242. 1880 was the worst, 1881 not quite so bad, and this year again is not quite so bad as 1881?—Not quite so bad.

6243. Am I right in supposing that the entries which you have given us in 1880 are the 26th of July, the 10th of September, and the 22nd of September?—Yes.

6244. May I take it that those are the only entries in your diary tor 1880 which bear upon the sewage question?—Yes.

6245. In 1881 you have, I see, a very large number of entries, and you have constant entries that you could not wash the decks on account of the sewage?—Yes.

6246. There is only one entry in your book for 1880 of that kind, and that is the entry of the 22nd of September?—That is very likely.

(*Mr. Lumley Smith.*) The 10th is the same thing. He was stoning the decks.

6247. (*Mr. Bidder to the witness.*) You tell me that 1880 was the worst year, and July I believe was the worst and the hottest month of it?—I do not remember exactly about the weather.

6248. How do you account for it that throughout that last year until we come to September there is no

entry suggesting that the condition of the water prevented your washing the decks?—Probably not; probably the boat's being under repair or something of that kind made it unnecessary to do anything of the sort.

6249. I do not like to be on probabilities. Is it a fact that the boat was under repair?—I do not know without I look to my book. I do not exactly remember everything like that.

(*Mr. Lumley Smith.*) You will find on the 26th of July an entry that they were not able to clean the cabins.

6250. (*Mr. Bidder.*) Now let me understand about this entry of the 26th of July. The vessel, I see, proceeded to the blocks at Greenwich, and while there, the crew were employed in cleaning the bottom. I presume then that at low water she was left dry upon the blocks?—Yes.

6251. And the crew therefore would be upon the mud under the bottom of the vessel?—On the ground; we have no mud there, only beach.

6252. Is that the day when the last witness Turnidge said that he felt ill?—Yes.

6253. Was he working at cleaning the bottom of the boat?—He was too ill to work.

6254. I do not think he told us what he was doing, but as a matter of fact, he was employed in the manner you describe?—He was on board the vessel for that purpose, but he did no work.

6255. Are you quite sure that he was not at work when he complained of being ill?—I am quite sure that I did not allow him to work.

6256. What time in the day did you begin cleaning the vessel's bottom?—I suppose we began at about 5 o'clock in the morning. We went up to the blocks at about half past three in the morning, or something like that.

6257. I see you say it was high water at 4.30?—Yes.

6258. What is the character of this Jestey's composition?—I really cannot tell you any more than that it is a paint.

6259. Is it a preservative paint for the bottoms of ships?—Yes, it is a very good paint; it does not corrode like most paints.

6260. It is a composition intended to be applied to the bottoms of ships?—Yes.

6261. What is its colour when it is applied?—When it first goes on it is a kind of lilac colour, and then it changes to nearly copper colour when copper is thoroughly clean; and it maintains that colour to the last.

6262. I see your entry states that both that and the black paint had got brown?—Yes.

6263. Do you mean that that happened in a night, or that it had been getting gradually so?—In the course of a day or two.

6264. How long had this composition been on?—I could tell you by referring to that book, but I could not tell you otherwise (*after referring to the book*). That Jestey's composition had been put on, on the 2nd of July.

6265. How often do you renew that composition, as a rule?—About twice a year if necessary. If it does not get rubbed, it does not want doing so often as that; it only wants doing about once in ten months.

6266. Do you say that the black paint had also turned brown?—Yes.

6267. Is that oil paint on the ship's side?—Yes, vegetable black.

6268. What time in the day was it that Turnidge complained to you of being unwell on the 26th of July?—Shortly after I got on board the boat which would be between three and four o'clock in the morning.

6269. Of how many men does your crew consist?—Six all told.

6270. Were any of the others incapacitated for work that morning?—No, not on that morning. All felt a little queer as I did myself.

6271. But you had not complaints from any of the others of being incapacitated for work except from Turnidge?—Only from Turnidge.

6272. Will you indicate a little more definitely where these blocks at Greenwich at which you say you were lying.

(*Sir John Coode.*) Is it a gridiron laid down on the beach?—Yes, it is at the Union Wharf, or I may say half a mile below Greenwich Pier.

6273. (*Mr. Bidder.*) That fixes it. I am not going through all these entries of yours, but there are a great many entries in which you describe the condition of the river as being filthy on account of the sewage stopping your watering the decks and so on; on those occasions when you entered in your log that the condition of the river was so polluted, did you take any samples of the water?—No, it was no duty of mine to do so.

6274. But you had been engaged frequently in taking samples with a view of showing the pollution of the river, had you not?—No, not up to that time; 1880 is the year you have in question.

6275. I asked you with regard to the whole. I told you I was not going to ask you particularly as to each one?—I thought you were alluding to the morning when the vessel was on the blocks.

6276. I have a series of entries here, all of which describe the condition of the river as being filthy in different words. Some of them say that it prevented you from washing the decks and holystoning them and so on; and there are entries both in 1880 and 1881, and also in 1882, I think. On any of those occasions when you so describe the water as filthy, did you take a sample of the water?—No.

6277. Neither in 1880, nor in 1881, nor in 1882?—No.

6278. You have already told me that you had been engaged at that very time in taking samples at different part of the river in 1881 and 1882?—We have taken samples from time to time, but the principal of the samples were taken when I was away on leave of absence in August 1881. I was away on a holiday at that time. I never saw any of the samples.

6279. There is one occasion on the date of the 18th of July on which you have an entry about anchoring the vessel off Greenhithe, going to Greenhithe to wash the decks in consequence of the filthy state of the river at Charlton. I see from the whole of the entry in your book that you went to Greenhithe on the duties of your station?—Yes.

6280. So that it was not a special journey for that purpose?—No, but when we got there we saw a drop of clean water, which was quite a treat, so I thought I would wash the vessel down with it.

6981. You have had a strong feeling all through on this sewage question, have you not?—I think anyone would who is constantly on the river.

6282. How did you make the observation of the sewage being within 12 inches of the surface?—I noticed that the river on the surface looked very clear and I thought it might be fit for use, and yet the water smelt very strong. So I ordered a bucket to be put overboard to draw some to have a smell at it; and when they drew the bucket up, I found that the black water followed the bucket. So I ordered the bucket to be put a little lower down and drew it up, and I found it was one black mass.

6283. Where did this happen?—At Charlton again.

6284. Then you lowered the bucket to a greater depth, as I understand?—About a foot beneath the surface.

6285. You also said generally that the river in the lower reaches was nothing but a mass of sewage at times?—At times.

6286. I suppose I am to infer that you mean that it is principally composed of sewage?—Yes, principally.

6287. The major part of it?—Yes, apparently all on the surface all discoloured; and on that occasion when I speak of its being so bad on the south shore in Long Reach; it was worse than I had ever seen it down there.

Re-examined by Mr. LUMLEY SMITH.

*Mr. G. Young.*

6 Dec. 1882.

6288. How often in practice do you wash your decks?—Every morning if the water is fit.

6289. Do you do it at other times if the water is bad?—I have to wait all manner of times now. Sometimes I keep the crew there till some time in the evening if I think there is a chance of the water being clear at all.

Examined by the COMMISSION.

6290. (*Chairman.*) You say you have known the river for 30 years?—Yes.

6291. When you first knew it, I think you said the water was pretty clean up to Gallion's?—Yes, very clean.

6292. For some time before the outfalls were opened, had not the vessels ceased to take water at Gallion's?—Some had; but most of the Shields vessels, such as I worked for, supplied themselves with water there in Gallion's.

6293. As lately as 1863 or 1864?—As late as 1863 or 1864, and also at Duke's shore on the high water.

6294. Has not the river very much improved in character since the opening of the outfalls above those outfalls up to London Bridge?—I should think it has greatly, from Greenwich upwards.

6295. At first you say that the river was very clean so that all the ships were able to take the water; whereas afterwards it got bad, so that only some of the ships were able to take the water; had not the river got worse then as compared with the time when you first knew it up to the time of the opening of the outfalls?—The upper part of the river had become very bad only as late as 20 years ago.

6296. From Blackwall up to London Bridge?—Yes.

6297. The river has improved since then?—The upper part has greatly improved in consequence of the removal of the drains.

6298. What time was it when the upper part got very bad as compared with the time when you first knew it?—I can remember the upper part 20 years ago, and also in the summer of 18 years ago it was very bad. I was attacked with the cholera in consequence of it.

6,299. Then, as I understand you, the upper part of the river was clean at first, then it got very dirty, and then it got better again after the opening of the outfalls?—Yes, the upper part.

6,300. Since the opening of the outfalls from the outfalls up to London Bridge the river has been a good deal improved?—Yes, all above Greenwich the river is really much better than it used to be.

6,301. (*Colonel Ewart.*) Have you any regular medical attendant for the men employed in your ship?—No.

6302. Do they go to their own doctors?—To their own doctors.

6303. (*Mr. Abernethy.*) You have stated that your vessel is moored at Charlton, and you have stated also that you could not wash the vessels' decks down on account of the state of the water; has the river improved at Charlton since the opening of the outfalls?—It has become filthy.

6304. That is below Greenwich, is it not?—It is a matter of six miles below Greenwich.

6305. (*Mr. Balfour-Browne.*) But it is above the outfalls?—Yes, about two miles above the northern outfall.

6306. (*Mr. Abernethy.*) What is the state of the river at Blackwall as compared with what it used to be?—The state of the river is not so bad at Blackwall as at Charlton; it gradually diminishes in its filthy state as it comes upwards.

6307. What is the state of the river at Blackwall as compared with what it was previously to the opening of the outfalls?—It is decidedly worse.

(*Mr. Lumley Smith.*) My learned friend asked a question as to whether this ship was under repair. This witness's first entry seems to be on the 21st of June, and I find that the ship was under repair until the 29th of June when she went on the gridiron at Greenwich and remained on the gridiron till the 9th of July.

6308. (*Chairman to the witness.*) Is that so?—That is so; she was under repair until the 12th of July.

6309. (*Sir John Coode.*) The first entry that you gave us was the 26th of July when you said that the water was so dirty that you could not clean the cabin?—Yes.

6310. (*Mr. Lumley Smith.*) Have you any entry in your book about samples being taken?—That would be in 1881 or 1882 if so. It would not be in 1880, because I do not remember anything of the sort.

6311. (*Mr. Bidder.*) I will not keep you now if you will let us have access to your books, if necessary, afterwards?—Yes.

6312. Perhaps you will look over them at your leisure, and let me know in the course of half an hour?—I will.

The witness withdrew.

Mr. JOHN PHILLIPS called in; examined by Mr. BALFOUR-BROWNE.

*Mr. J. Phillips.*

6313. You live at Putney, do you not?—I do.

6314. And you were formerly chief surveyor to the Metropolitan Commissioners of Sewers?—I was.

6315. I think you were appointed to that office in the year 1847?—Yes, towards the end of the year.

6316. The Metropolitan Commissioners of Sewers had the entire management of the sewers of the Metropolis until the time when they were passed over by the Act of 1855 to the Metropolitan Board of Works?—Yes.

6317. I think you were at one time the chief surveyor to the Westminster Commission, were you not?—Yes, I was for two or three years. Previously to that, I was clerk of the works in the several districts for about two years.

6318. So that when you were appointed chief surveyor to the Metropolitan Commissioners of Sewers you had had considerable practical experience both as clerk of the works and as a surveyor?—That is so.

6319. Had you at that time made practical observations upon the sewers with a view to finding out the velocity at which sewage must flow in order to prevent deposit?—I was very anxious to ascertain that fact, finding that there was a large quantity of deposit in the sewers. I set to work making observations and experiments in the sewers, and the result of my observations and experiments was that the sewage must flow with a velocity of not less than $2\frac{1}{2}$ feet per second, or 150 feet per minute, in order to prevent the fœcal and other matters in suspension from depositing.

6320. In what sewers did you experiment?—In the Westminster sewers.

6321. Did your observations extend both to large sewers and to small branch sewers?—I found that whether the quantity of sewage was small, as in a branch sewer, or large as in a main sewer, the flow must be at the same rate of velocity of $2\frac{1}{2}$ feet per second so as to maintain sufficient force and energy in the stream to prevent the sewage matters from depositing.

6322. Are there in the Metropolis many sewers in

which the sewage does not flow at the rate which you have indicated?—There are hundreds of miles of sewers of this kind now in the Metropolis. These are called "deposit sewers," from the fact that the sewage does not flow at the rate of velocity which I have stated.

6323. Is that name "deposit sewer" used in reference to those sewers?—Yes.

6324. How are those sewers constructed; what is the shape of the bottom of them?—They have very nearly flat bottoms, wide flat bottoms with upright sides and arched top. In consequence of that shape the sewage spreads over a large surface and has no proper power and velocity to raise and carry away the fœcal and other matters.

6325. Of course the more you shaped it like a V, the more scour you would have?—The more you concentrate the flow in a narrow bottom of a V shape, the greater velocity you get to remove the sewage matters.

6326. And the more you flatten it out, the less velocity you get and the less scour?—Quite so.

6327. When you were chief surveyor to the Metropolitan Commissioners of Sewers, where did the main sewers of the Metropolis discharge?—Into the Thames.

6328. And where were their outlets; were they above or below the level of low water?—They were considerably above the level of low water.

6329. Do you remember the removal of old London Bridge in 1834?—I do. I saw it pulled down.

6330. Before old London Bridge was removed, what effect had it upon the water above the bridge?—In consequence of the large number of the piers of the bridge they acted like a dam across the river. In consequence of that the low water level above the bridge was four or five feet higher than it was below the bridge.

6331. When the bridge was removed, was the level of the water at low-water mark reduced in this part of the Thames above the bridge?—It went down to the lower level, which enabled the flat marsh districts of Lambeth and Battersea on the south side of the Thames, and of Westminster and Pimlico on the north side, to be drained four or five feet lower than they had ever been drained before.

6332. Under those circumstances, the water above the bridge being lower at low water, was there a much greater exposure of river bank than formerly?—There was a great deal more.

6333. In consequence of the exposure of a larger amount of river bank, or mud, was the sewage in this part of the Thames above bridge exposed upon the mud?—It was; it used to spread all over the banks and cause a deposit of sewage mud. For instance, between Westminster Bridge and Northumberland Street, Strand, where two or three main sewers discharged into the river, the deposit of sewage mud was not only large, but it went on increasing until the surface became covered with myriads of small red worms. The same was to be seen at other places near the outlets of the sewers.

6334. Do you remember anything that the Commissioners did with a view of preventing that?—Yes, we formed wood channels from the outlets of the sewers down to low water mark.

6335. (*Sir John Coode.*) Wooden trunks, I suppose?—Yes.

6336. (*Mr. Balfour Browne.*) With a view of carrying the sewage down from the sewers to low-water mark?—So as so prevent it from spreading over the river banks.

6337. Did that expedient have the desired effect?—Very little indeed.

6338. Was it brought back on the flood water?—The flood tides returning carried the sewage over the banks, and they were as bad as they were before.

6339. I believe that in the year 1846 there was a Mr. George Hawkins who was a coadjutor of yours?—Yes.

6340. And he and yourself made certain calculations with regard to the quantity of sewage flowing into the Thames?—Yes, he and I together made gaugings at the outlets of all the main sewers discharging into the Thames from the Westminster district; and after making our gaugings we made calculations from them of the quantity of sewage discharged into the Thames.

6341. Do you remember the result of those calculations?—Yes, the result was that the quantity of sewage discharging from the Westminster district per day of 24 hours was 1,798,094 cubic feet.

6342. Did you take any means of ascertaining at the same time how much water was being supplied by the water companies to the district from which that sewage flowed?—We ascertained the quantity of water supplied to the houses by the different water companies, and as far as we could make out, the quantity of sewage discharging into the Thames, was about equal to the quantity of water supplied to the houses by the water companies.

6343. At that time were the houses in that district that you are speaking of supplied with cesspools?—Yes, there was at that period one and sometimes two or three or more cesspools to almost every house in the Metropolis.

6344. Were those cesspools connected with the sewers in any way?—There was an overflow drain from them into the sewers in front of the houses.

6345. Do you remember when you began to abolish the cesspools?—I think it was in 1848. In the densely inhabited parts of the Metropolis, under the jurisdiction of the Commissioners, we emptied and filled up the cesspools, substituted pan waterclosets for them, and laid stoneware pipe drains from these into the sewers.

6346. Did you at that time calculate the amount of matter that might be collected in cesspools within your district?—I calculated, from data which I collected, that the capacity of the whole of the cesspools in the Metropolis on the north side of the river was equal to a canal 20 feet wide, about 5 feet deep, and 10 miles long extending right through London from Hammersmith to Bow.

6347. And these cesspools, or this hypothetical canal was full of fœcal matter?—Yes.

6348. And decomposing in the midst of the population surrounding it?—Yes.

6349. And in the process of decomposition emitting all sorts of gases of course amongst the people?—Yes, quite so.

6350. Was all that matter, which you have been describing, pumped out and discharged into the sewers?—Yes, it was, and washed through the sewers into the river.

6351. And so it found its way into the river Thames?—Yes.

6352. Just before the cesspools had been cleared out in the way you have described, is it a fact that there had been a serious epidemic of cholera in London?—There had been cholera very severely.

6353. And the Commissioners of Sewers at any rate adopted the system of turning all the sewage into the Thames rather than allowing it to decompose in the cesspools?—Yes. Of two evils it was thought to be the least to put what was in the cesspools and in the sewers into the Thames, rather than allow it to remain and so go on decomposing in them amidst the population.

(*Chairman.*) That outbreak of cholera of the year 1849 is a matter of historical notoriety.

6354. (*Mr. Balfour Browne to the witness.*) In consequence of this action of the Metropolitan Commissioners of Sewers, did the river become much fouler than it had hitherto been?—Very much so.

6355–6. And I believe that in consequence of the foul state of the river there was such an outcry, that it occurred to you, amongst other persons, to see whether some means could not be adopted for getting rid of the sewage altogether from the river?—Yes, it led me to consider the question of the formation of a system of outfall sewers not only for the Metropolis, but for

*Mr. J. Phillips.*

6 Dec. 1882.

the towns in the valley of the Thames right up to Windsor, as a substitute for the river.

(*Chairman.*) Do you not think that we are going very far in asking the ideas of this gentleman in 1849? I do not see what the drift of the examination is.

(*Mr. Balfour Browne.*) I think it was out of these ideas that the main drainage system of the Metropolitan Board ultimately arose.

(*Chairman.*) That may be very interesting and very honourable to the witness, but how does it affect this inquiry?

(*Mr. Lumley Smith.*) It is leading up to some experiments which he made.

(*Chairman.*) Then let us come to the experiments at once.

6357. (*Mr. Balfour Browne.*) It was in consequence of these ideas that he made certain tidal experiments which were ultimately utilized. (*To the witness.*) In 1849 was Mr. Frank Forster appointed engineer to the metropolitan commissioners?—He was.

6358. And I believe he was directed to design plans for the disposal of the sewage by means of outfalls, in the way you have been speaking of?—Yes.

6359. In the year 1850 he laid before the Commissioners a scheme for the interception of the sewage from the south side of the Thames, did he not?—He did.

6360. The works as designed by Mr. Forster, I think, were not commenced until the whole of the sewers were passed over to the Metropolitan Board.

(*Mr. Bidder.*) Does my learned friend suggest that the works were afterwards carried out? I have never heard that Mr. Forster's works were carried out.

(*Chairman.*) Whether Mr. Forster's scheme was carried out or not, is a very long way from this inquiry.

6361. (*Mr. Balfour Browne to the witness.*) Mr. Forster's scheme was to intercept the whole of the drainage on the south side of the Thames, and carry it into the Thames?—Yes, at some miles down the river from the Metropolis.

6362. Before that scheme was designed, had any tidal observations been made upon the river at all?—None whatever.

6363. I think in 1850 Mr. Forster prepared a similar scheme for intercepting all the drainage on the north side and carrying it into the Thames?—He did.

6364. Before that date had any tidal observations been made upon the river at all?—None.

(*Chairman.*) This witness cannot tell us about Mr. Forster's plans.

6365. (*Mr. Balfour Browne.*) Before these plans were designed, to your knowledge there were no observations with regard to the tide at all?—None, as regards the distances to which the tides would carry the sewage down and up the river from the points and periods of its discharge into the river.

6366. In May 1851, I think after the sites of the outfalls had been determined upon, you and a Mr. William Betts, your assistant, were directed to make tidal observations by Mr. Forster.

6367. (*Chairman.*) This is leading the witness into a matter that seems quite irrelevant. If the witness made any experiments which seem to you to be in any way material to our present inquiry, let us come to those experiments. (*To the witness.*) Did you make any experiments?—I did.

6368. In pursuance of certain orders which you received from Mr. Frank Forster the engineer, to the Metropolitan Commissioners of Sewers?—Yes, I made some tidal observations.

6369. In what year was it that you first made those experiments?—In 1851.

6370. (*Mr. Balfour Browne.*) Was that after the site of the outfalls had been fixed?—Yes.

6371. (*Chairman.*) Do you mean the Crossness and Barking outfalls?—The Barking Creek outfall.

6372. What did the experiments consist of?—We made tidal observations in the river by means of a float.

6373. On what day?—They extended over various days. Our report of the experiments is as follows:—

"Northern Drainage.

"Experiments on ebb and flow of tide in the River Thames.

"7, Hatton Garden,

"Dear Sir, 8th July 1851.

"In accordance with your instructions received on the 31st day of May, we have made a series of experiments to ascertain to what distances the sewage matter proposed to be emptied into the Thames at Barking Creek would reach at different times of the tide, and beg herewith to hand you the accompanying tables showing the various results of these experiments. The float used was of wood (6 feet long, 15 inches square at the bottom and 6 inches square at the top, and on the top of that was a flat piece of wood 15 inches square. There was a hole in the top of the float and there were perforations towards the bottom: and, in order to get the float to stand upright, we put some pebbles in to ballast it) and it was always kept in the strength of the tideway by being carefully shifted whenever it had a tendency to get into the slacks or eddies.

"The first experiment we commenced at high-water opposite Barking Creek, and the float drove down with the ebb by low-water 14 miles and returned with the flood 13¾ miles, being within quarter mile of the point where it was put in.

"2nd experiment. Float put in opposite Barking Creek one hour after high water, it drove down with the ebb by low water 13½ miles and came back with the flood 13¼ miles, being within quarter mile of the place where it was put in.

"3rd experiment. Float put in opposite Barking Creek two hours after high water, it drove down with the ebb by low water 10 miles, the wind blew so high that there could be no truth in the driving of the float, so discontinued.

"4th experiment. Float put in opposite Barking Creek at high water, it drove down with the ebb by low water 13¼ miles, and returned with the flood 10¼ miles.

"5th experiment. Float put in opposite Barking Creek one hour after high water, it drove down with the ebb by low water 11 miles and returned with the flood 10¼ miles.

"6th experiment. Float put in opposite Barking Creek two hours after high water, it drove down with the ebb by low water 10¼ miles and returned with the flood 13¼ miles, being 3 miles above Barking Creek.

"7th experiment. Float put in two hours after high water opposite Barking Creek, it drove down with the ebb by low water 11¾ miles and returned with the flood 13¼, being 2 miles above Barking Creek.

"8th experiment. Float put in two hours after high water opposite Barking Creek, it drove down with the ebb to low water 10½ miles and returned with the flood 13½ miles, being 3 miles above Barking Creek.

"9th experiment. Float put over one hour after high water opposite Barking Creek, it drove down with the ebb by low water 14¼ miles and returned with the flood 14 miles.

"10th experiment. Float put in at high water opposite Barking Creek, it drove down with the ebb by low water 15 miles and returned with the flood 13½ miles.

"11th experiment. Float put in three hours after high water, it drove down with the ebb by low water 7¼ miles, the wind then came on to blow so strong that we were obliged to desist, but supposing the flood to act the same as it did in the last experiment, the float would have gone up 13 or 14 miles, being about Greenwich.

"12th experiment. Float put in two hours after high water opposite Creek's mouth, it drove down with the ebb by low water 8 miles, and returned with the flood 9¾, being 1¾ miles above Barking Creek. This experiment was continued without stopping for

10 whole tides, by which time the float reached at low water a point 27 miles from Barking Creek, and at high water 19 miles, being 4 miles below Gravesend. This experiment was commenced between the spring and neap tides, and, as the tides took off, the float gradually worked lower and lower down the river at each high water time, and had the experiment been continued on to the next springs we are of opinion that the float would have gradually worked its way up the river at each high water time, until at high water or the best springs it would have been only 15 miles from Barking Creek or about Gravesend.

"13th experiment. Float put in two hours after high water opposite Barking Creek, it drove down with the ebb by low water 8 miles and returned with the flood 11¼ miles, being 3¼ miles above Barking Creek. This experiment was then continued tide after tide for eight tides, when we found the float arrived at low water 7 miles below Barking Creek, and at high water 7½ miles above, being opposite Deptford Dockyard. This was the highest spring tide. We then continued on again for five more tides, and found the float then at low water 10 miles below Barking Creek, and at high water 5 miles above it, showing as in the continuous experiment, No. 12, that as the tides take off, the ebbs become more powerful than the floods, and consequently each tide carries the float further down the river. This experiment was commenced as the springs began to increase, and shows up to the eighth tide that the floods during the springs were more powerful than the ebbs, after which, as just before observed, the ebbs gradually obtain the mastery. From the above experiments we would beg to observe that in five trials, the float each time being put in opposite Barking Creek two hours after high water, it has always returned above the point at which it was put in on an average for a distance of 2½ miles. We could venture to suggest that before giving any decided opinion as to the deposit range of sewage proposed to be put into the River Thames at Barking Creek, another series of experiments should be made, one commencing at the lowest neap tides, and continuing on through the springs to the lowest neaps again; and the other beginning at the highest springs, continuing on through the neap to the next highest springs. These experiments should not be delayed, as the nights now are at their shortest and it is extremely difficult and dangerous to watch or tend the float in the dark, especially when (as often happens) there are many large steamers and other vessels going up and down the river; and also that we might take advantage of this fine weather, as no dependence can be placed on the accuracy of the floats driving when there is much wind.

"We are, dear Sir, your obedient servants,
"William Betts, jr.
"John Phillips."

6374. (*Chairman.*) Could you fix the time of the year when these experiments were made?—In the month of June, just before we made the report.

6375. (*Mr. Balfour Browne.*) The instructions were given on the 31st of May. (*To the Witness.*) Did you follow the float yourself in a boat?—Yes.

6376. So that all these experiments were made by yourself, and this is the result of your own observation?—Quite so. No one was engaged in making these experiments but myself and my assistant William Betts.

6377. You recommend in that report that another series of experiments should be made?—Yes.

6378. Were you instructed to make them?—Yes.

6379. And did you make a second report dated the 11th of September, 1851?—Yes, I will read it—

"*Northern Drainage.*

"7, Hatton Garden,
"Dear Sir, 11th September, 1851.

"Herewith we beg to hand you the result of the two last continuous experiments made to ascertain the relative strength of the ebb and flow of the tide in the river Thames. The first you will perceive was commenced two hours after high water on the top of the springs, and the second two hours after high water at the lowest neap tides, the point of commencement being opposite Barking Creek, as in the experiments previously made.

"The first was commenced on the 15th July two hours after high water, the float being put in opposite Barking Creek; and by low water it drove down to a point 11½ miles below the starting point, and returned with the flood to a point one mile above Barking Creek at high water. The next ebb the float drove down to a point 11¾ miles below Barking Creek, being a distance of 12¾ miles for the whole driving of one tide, and the next flood the float drove up to Barking Creek by high water; and so we proceeded tide after tide with little variation. As the floods became weaker the ebbs were (in proportion) stronger, and as will be seen by the accompanying sheet the float worked lower down the river by each succeeding high water until the 24th of July when it reached a point at high water 13 miles below Barking Creek, after which, as the floods again became each day stronger, every tide worked the float higher up the river, until on the 29th July it had reached a point at high water only five miles below the Barking Creek, thus giving as the excess of strength in the ebbs over the floods for 15 days' driving, only five miles.

"The next experiment was commenced two hours after high water at Barking Creek on the 6th August, the tides being then the lowest neaps, and the float gradually worked up the river each succeeding high water until the 12th August, being the highest spring, it reached a point 6¼ miles above the Barking Creek at high water; and from that time until the 20th it gradually worked down the river, tide by tide, when it reached at high water a point 9½ miles below Barking Creek. As in the former experiments, there are some seeming anomalies, yet it proves very satisfactorily that all that had been done before was in the main correct.

"The deduction we draw from these experiments and to which we most respectfully beg to draw your attention is the fact that if the sewage be not put into the Thames at Barking Creek at some period earlier than two hours after high water each tide, there will always be the certainty of its going up the river as far as Greenwich; and should a long continuance of northerly winds happen just after the times of lowest neaps, there is every probability of its being driven up so far as Rotherhithe.

"We have made several experiments by putting the float over at high water, and the result of these experiments is that the sewage should be poured into the Thames at or as near after high water as possible, to effect which the bottom of the reservoir must be not more than 2 feet below average high-water mark, or 9 feet above Ordnance datum. This would give (allowing the invert of the sewer to be 1 foot above bottom of reservoir) a fall from the crossing the North Woolwich railway to the reservoir of 2 feet 6 inches per mile, a fall, considering the situation, ample for all practical purposes.

"The sewer, of course, would have to be made of greater capacity than when a uniform inclination of 4 feet per mile was proposed; and should you coincide with the view we take of this matter we will lay the gradient down on the main upper line as here proposed, viz.: from the reservoir to the crossing of the North Woolwich railway at the rate of 2 feet 6 inches per mile from the crossing of the North Woolwich railway to the crossing of the East and West India Docks and Birmingham Junction Railway at the rate of 2 feet per mile, and from that point to the junction of Ranelagh sewer, Uxbridge road, at the rate of 4 feet per mile.

"We are, dear Sir,
"Your obedient servants,
"John Phillips,
"William Betts, Jnr."

*Mr. J. Phillips.*

6 Dec. 1882.

6380. (*Mr. Balfour Browne.*) Do you know of any other trial experiments which were made with the exception of those which you have been speaking of to the Commission?—No, I do not; no other experiments of the kind were made.

Examined by the COMMISSION.

6381. (*Colonel Ewart.*) All your experiments were made in the summer time, were they not?—They were.

6382. Do you recollect whether it was a dry summer or a wet summer?—It was a dry summer and very fine weather.

6383. (*Prof. Williamson.*) You told us some time ago that a considerable quantity of solid matter is deposited in the sewers?—Yes.

6384. Of what nature is that solid matter, is it sand, earthy matter, or what is it?—It is partly silty matter, but chiefly soil matter.

6385. Do you mean night soil?—Yes, night soil and general house and street refuse matters, partly liquid and partly solid, which are thrown down and washed into the drains.

6386. Have you frequently had occasion to remove it from the sewers, and examine it and see what it is?—Frequently, and it was of the character that I have told you.

6387. When you said that a velocity of $2\frac{1}{2}$ feet per second in this liquid prevents any deposition, does that statement apply to the various kinds of solid matter, to the silt and also to what you call soil?—To the silty matter, the fœcal matter, and all kinds of organic matters that pass into the sewers, and form, with the liquids, the compound called sewage.

6388. Do they all require the same velocity to prevent the deposition, or do some require a greater velocity than others?—The ordinary sewage requires that velocity to prevent the matter held in suspension from depositing.

6389. (*Chairman.*) You say the ordinary sewage; is that a mixture of the two, the sandy matter and the fœcal matter, or the fœcal matter alone?—There is a very small quantity of silty matter as compared with the fœcal matter and the various other matters which I have referred to.

6390. But your observations as to the $2\frac{1}{2}$ feet per second relates to the composition of the fœcal and the sandy matter?—Yes. Of course it does not apply to pebbles or rubbish or anything of that nature.

6391. (*Professor Williamson.*) Did not your float often get aground?—We never suffered it to get aground. We always followed it, and whenever there was a tendency for it to run into the slacks or into the eddies the man who was following it (sometimes I should be in the boat with him myself) always laid hold of the float and towed it out into the strength of the stream.

6392. You put it where the stream was strongest?—Yes.

6393. So that it does not give the average velocity but the greatest velocity?—The greatest velocity. We always kept it as much as we could in the strength of the tide.

The witness withdrew.

Captain EDWARD BURSTAL, R.N., called in; examined by Mr. LUMLEY SMITH.

*Capt. E. Burstal, R.N.*

6394. I believe you are a captain in the Royal Navy?—Yes.

6395. And I believe you are the secretary to the Thames Conservancy Board?—I am.

6396. When did you first know the river Thames?—In the year 1832.

6397. Were you for some time after that employed under Captain Bullock, who made a survey of the river by order of the Admiralty?—I was.

6398. I think that the charts were on a large scale, 20 inches to the mile, and the depth of water shown on them was the ordinary low-water spring tide, 19 feet 9 inches, below Trinity high-water level?—That is the scale, and that is the depth to which they were reduced.

6399. In 1861 the Conservators directed a survey to be made of the river on the same scale as that of 1832, did they not?—They did.

6400. And you have compared those charts, have you not?—Yes, I compared the Admiralty charts of 1832 with the Conservancy charts of 1861.

6401. There are, I believe, one or two points of difference which you desire to point out. Halfway Reach is the reach before you come to Erith, the reach in which the Crossness outfall is situated?—Exactly.

6402. Do you find much difference between the depths in the fairway or midchannel of Halfway Reach?—No, there was very little difference. The Admiralty chart of 1832 and the Conservancy chart made from the survey of 1861 agreed very nearly indeed. There was scarcely any difference between these two charts, through what was well known as the Fairway Channel in Halfway Reach all the way down.

6403. You have the charts here, I believe?—I have.

6403*a*. There have been certain spits taken away, have there not?—Between 1832 and 1861 a great many hand-dredgers were at work under license from the Trinity House, and those hand-dredgers dredged away the spit at Leather Bottle Point or Halfway House Point, at the upper part of Halfway Reach, and they dredged away the sand spit off Jenningtree Point, which is at the lower end of Halfway Reach.

6404. Are they both on the same side of the river?—Both are on the south side of the river.

6405. Then those appear in the charts of 1832, but not in the charts of 1861?—They do not appear in the chart of 1861.

6406. Can you tell us what, if any, change that made in the current of the stream?—I cannot say positively what the change was, but all I can say is this: that having two long spits of sand removed from the point, the stream running either ebb or flood, the ebb tide against the Leather Bottle Spit, or the flood from Jenningtree Point Spit, would have a tendency, and a very material tendency, to conduct the stream more towards the middle, or south side, of the river than it would when those spits were tending to divert the stream towards the north side of the river.

6407. Would that be equally true of the flood and the ebb?—Yes.

6408. Besides those spits, have any banks been dredged away?—Yes, there were some banks removed, by whom I cannot say, but there were in 1832 some very long narrow ridges of gravel shoal on the northern side, the Dagenham Shoals, as they were called, having eight or nine feet of water over them, and they were removed to a great extent before 1861. They do not appear in the 1861 chart.

6409. That 1861 chart would be shortly before the outfalls were opened?—Some few years before the outfalls were opened.

6410. (*Mr. Michael.*) Three years before?—Yes.

6411. (*Mr. Lumley Smith.*) We have heard that there has been a great amount of dredging done at the Rand's Hill?—That is a shoal in the middle of the river about three-quarters of a mile below Erith.

6412. That has been done since 1861, I believe?—I think it began about 1861, but I am not quite sure.

6413. But it appears, I presume, in the 1861 chart?—It does. I know that the shoal was there in 1861.

6414. In Barking Reach, is there now any bank or shoal which does not appear in the chart of 1861?—There is a quantity of mud deposited on the south shore between Margaretness on the south side of the river and Leather Bottle Point on the south side.

(*Mr. Michael.*) That was one of the subjects of inquiry before the arbitrator.

6415. (*Mr. Lumley Smith.*) Does that quantity of mud amount to a bank?—Yes; and there is also a large quantity on the north side below False Point.

6416. First of all, with regard to the bank on the north side of Barking Reach, will you tell the Commission what that is?—That is a mudbank which has accumulated to a very great extent below the Powder Magazine, about three-quarters of a mile below Barking Creek.

6417. That has accumulated since when?—Since the sewage has been sent out into the river—since 1861.

6418. I do not think you gave me the dimensions?—I do not know them without measuring on the chart.

6419. It is a considerable bank, is it not?—Yes.

6420. Have you examined it at all to see the character of the stuff of which it is composed?—Yes, I have done that.

6421. What, in your opinion, is it composed of?—Very black mud, very deep and very slimy, and with not much sand or gravel in it.

6422. Have you compared it at all with the Thames mud at a distance from the outfalls?—It does not appear to me that that mud is at all like the mud that is found on the shore in this river, or any other river that I know, just outside the banks between high and low-water mark. It is not in any way of the same character.

6423. Are there any other characteristics of it at all that would lead you to an opinion as to it; does it smell in any way?—In warm weather it smells very badly; and in cold weather you may get the mud up from the bottom of the river almost opposite the outfall, and you cannot smell it. In cold weather I have got the mud up from the middle of the river opposite the sewer and in many other places, and you cannot detect any smell from it.

6424. Are you speaking now of the same places?—I am speaking of the shoal exactly opposite the outfalls and the mud in Erith Reach.

6425. But are you speaking of this same bank which smells badly at some times and not badly at others?—I must candidly confess that I have not been to all these banks at various times of the year; but I have been in the summer, in hot weather, when the mud has stunk very badly indeed; and I have been there in the winter to the same sort of bank, and I have not been able to detect any smell.

6426. Have you tested that bank in particular in the winter?—Not that bank in particular, but I have tested other banks close to it.

6427. Are you able to tell the Commission how the tide sets from the Barking outfall?—I remember it quite well, for I took the set of the stream last year. I put one float in at Barking Creek close outside of low-water mark, and it drifted with a very strong current all along that northern shore until it got to False Point; that is to say, the north shore of Barking Reach. There it gradually set off, that is to say, there was a bay to the eastward of False Point, and below False Point in that bay it was slack water. In that bay is the place where there is so much mud deposited. From thence it took a middle course and went down Halfway Reach about three parts across on the northern side and straight down the reach That was the direction of that current. Then there was another stream which I was very curious indeed to take, and at the same time I started a float 7 or 8 feet long, submerged its whole depth excepting about 9 inches, say. I put that float in 100 feet off Leather Bottle Point, quite close in on the south side. That float followed the southern shore right away down to within 350 or 400 feet of the wharf of the southern outfall buildings, and it went parallel with the southern shore all the way down the reach until it got half a mile below the outfalls. The velocity of the current was 2½ miles an hour. That was very curious, and I was much surprised when I saw it, but that is the fact, and it is plotted on the chart. The floats that were being put in on the other side in the main channel over against the Dagenham shoals at the same time were going at the rate of about 2¾ miles an hour; there was about a quarter or half a mile difference in the velocity of the current.

6428. Leather Bottle Point is just above the Crossness outfall, I think?—About half a mile or three quarters of a mile above the Crossness works.

6429. There is a bank, I think you have told us, on the south of Barking Reach?—Yes, between Leather Bottle Point and Margaretness.

6430. That has accumulated since when?—Since the outfalls have been at work.

6431. Do you make a distinction between 1861 and 1864?—No, I have not observed that, except that I compared it with the new chart of 1861 and showed that a bank had formed since the outfalls were opened on the south side.

6431*a*. (*Mr. Michael.*) Since 1861, you mean?—Yes, since 1861.

6432. (*Mr. Lumley Smith.*) What is the character of the composition of that lower bank?—That is a black muddy bank too.

6433. Of the same class as the other?—Very much so.

6433*a*. What slack water would there be, according to your view, in Barking Reach?—The slack water in Barking Reach would be on the south shore at the very place where that bank is; and if I may venture to make the remark, I consider that that bank is caused by the dirty muddy water stirred up by the paddle wheels and screws of steamers over that large shoal which formed off the southern outfall works, and brought up the river by the flood current; and when it comes round Leather Bottle Point and flows up Barking Reach it gets into the eddy, and there it is deposited.

6434. Whatever matter is in suspension, and wherever it came from, it would naturally deposit when it got into slack water?—Yes.

6435. Used that southern part of Barking Reach to be used by colliers?—Yes, always, as long as I can remember, for vessels that had to come up the river and wait until their cargoes were sold at the market; they would be brigs drawing 16 feet of water.

6436. And in Halfway Reach also?—I am speaking of Halfway Reach, not Barking Reach.

6437. Used there to be colliers, sections for brigs, there; I think that is the technical term?—It was a place set apart by the Corporation of London for vessels to lie at until their cargoes were sold.

(*Chairman.*) Is this going to the question of navigability?

6438. (*Mr. Lumley Smith.*) No, the question of the navigation has been disposed of; but in considering how far the river is suited for sewage discharge, it is necessary to know what the river consists of, and I believe contour sections have been taken. (*To the witness.*) What used those vessels to draw?—16 feet.

6439. And that is where you now find this bank?—Yes; now there is about seven or eight feet of water.

6440. Was that part of the fairway of the reach?—That was when I first knew the river, and for many years afterwards the fairway of the reach right down to the southward of mid-channel of Halfway Reach.

6441. How soon after the sewage works had got into full operation was the attention of the conservators drawn to the state of the river?—I am not quite sure, but I should think about 2½ or 3 years afterwards.

*Capt. E. Burstal, R.N.*

6 Dec. 1882.

6442. What course did the conservators take?—They ordered a survey to be made of the river, and that survey was made and the plans compared with the soundings of 1861.

6443. Was that survey reduced to writing?—Yes, it is on a chart. We have the chart in the room.

6444. Are you able to tell us the result of the survey?—Yes, the result of it was this: that a large mud bank had formed and was forming off the southern outfall, off the works on the southern side of Halfway Reach; and that mud bank occupied the place that the deep water channel used to be in. On that mud bank there were in the new survey 8 or 9 feet of water at low water spring tides, where, according to the survey of 1832, and the chart of 1861, there were depths of 15 to 16 feet.

6445. I will take you now to Erith Reach, that is rather below; comparing the chart of 1832 with the chart of 1861, did you find that there had been much dredging executed in Erith Reach?—A great deal. A large portion of it was done in the upper part of Erith Reach, that I just referred to, off Jenningtree Point. Another large portion was the middle ground, about halfway down the reach, nearly in mid-channel, which had only four feet of water over it at low water spring tides. There was another shoal off Cold Harbour Point, at the lower end of the reach, which extended a long way out, and that was also removed. So that in the chart of 1861 neither of those shoals appears.

6446. The water then had been deepened considerably in Erith Reach?—Yes; I should say that 13 or 14 feet of deepening had taken place in Erith Reach.

6447. Did you find that there was any alteration in the sectional area between 1832 and 1861?—I did not measure it exactly with that object in view, but I found that the shoals had been removed, and I found, on comparing the depths on the Admiralty chart of 1832 with the depths on our chart of 1861, that the soundings and the depths of water at Erith were actually deeper in 1861 than they were in 1832. That is shown plainly on the plans and sections that I have prepared.

6448. Then the water had deepened; would that be in front of the town?—Along the whole front of the town at Erith, from Church Hole down to where the Erith jetty is, Easton's and Anderson's works, the low water mark was closer to the shore in 1861 than it was in 1832.

6449. Then there had been no accumulation of mud at Erith at that time?—Not only was there no accumulation of mud at Erith at that time, but, if you examine the charts, putting the tracing of one date upon the tracing of another, you will there see by the different coloured figures that the water was actually deepened during that period off Erith.

6450. A survey was again made in 1879?—Yes.

6451. And you have the chart?—Yes.

6452. What change do you now find in Erith Bight?—I find, by comparing the depths in Erith Bight, by taking a chart of the same scale, and laying it on the two other charts, that a very large accumulation of mud has taken place in Erith all the way along the shore in 1879, to the depth of seven or eight or ten feet vertically.

6453. Along what distance of shore do you find this accumulation?—I should think half a mile or three quarters of a mile, all along Erith town.

6454. That would appear by the chart, I suppose?—Yes, the charts and sections will show it.

6455. Had the depth of water increased or decreased in 1879 as compared with 1861?—It had decreased.

6456. Where do you find that it has decreased?—All the way from Erith Church by the Corinthian Yacht Club Causeway the whole length of the town of Erith, I should think, down to the pier.

6457. You have sounded the mud yourself, have you not?—Yes, I have tried it with an iron pole.

6458. What depth do you find?—I have gone down nine feet of mud before it came to a hard bottom.

6459. What kind of mud is it?—Black, very nearly the same sort of mud as I described further up.

6460. I think that as late as October 1882, that is a couple of months ago, another survey was made of the river in that locality?—Yes, the sections are plotted on the same scale there to show what it is now in October 1882.

6461. I presume that somebody else will speak to those?—Yes, those who made that survey will speak to their accuracy, I saw them plotted. They show that there is still an accumulation going on.

6462. In 1879 did the conservators receive any petition from the inhabitants of Erith?—They did.

6463. What was that for?—The petition was that the Conservators would elongate the Causeway because so much mud had accumulated at the end of it.

6464. (*Chairman.*) Did you elongate the Causeway?—We did. The engineer made a report upon it.

6465. (*Mr. Lumley Smith.*) Mr. Leach your engineer, who is now dead, I believe reported, and you did elongate the Causeway?—He reported on his examination of the place and of the mud that was formed near the Causeway.

6466. You have seen it, I suppose?—Yes, I have.

6467. Do you know the amount of increase?—I think they lengthened it 150 feet; it was upwards of 100 feet, I know, and it was made a floating causeway kept down by chains.

6468. (*Chairman.*) I think we had one witness who said 120 feet?—I forget, but I should think it is 150 feet longer.

6469. Have you seen the warping buoy which is moored off the ballast wharf?—I have seen the chart of it.

6470. What does it appear at low water?—I believe there are only two or three feet of water there at low water now. There used to be 13 feet.

6471. (*Prof. Williamson.*) You say that you believe it; do you know it yourself?—Yes, at the warping buoy.

6472. (*Mr. Lumley Smith.*) The chart shows two or three feet?—Yes.

6473. Where do you get your depth at previous times?—At 19 feet 9 inches below Trinity high water. They use 20 feet in round numbers now, so that it is a little lower than it was in former days. We get it from the office chart. When they applied for the buoy there was a plan showing the depth of 13 feet.

6474. Have the Corinthian Yacht Club recently extended their causeway?—They have.

6475. Was that done by permission of the Conservators?—They asked permission, and it was given.

6476. What was the ground of that request?—Because the mud had accumulated so much that they could not get their boats in.

6477. Some questions have been asked as to whether the removal of Erith Rands Hill may have caused this deposit of mud at Erith Bight; have you an opinion upon that subject?—I have heard that such questions have been raised. I cannot imagine for one moment that the removal of a shoal which was in the middle of the river, about three quarters of a mile below Erith, could have any possible effect in causing a deposit there. I should think it would be exactly the other way.

6478. (*Mr. Bidder.*) It would be fair to direct Captain Burstal's attention to a shoal directly opposite Erith Bight. I do not know whether its name is Rands or not?—It is three-quarters of a mile below the town. I am speaking of Rand's Hill.

6479. The one meant to be suggested is a shoal exactly opposite that very bight?—I never knew of a shoal there. You must tell me what shoal you are alluding to.

6480. (*Mr. Lumley Smith.*) We have heard that the crown of Rand's Hill was removed by the Trinity House and that the dredgers afterwards removed a good deal more of it; would the removal of the Rand's Hill make any difference?—No.

(*Mr. Bidder.*) It is my mistake as to the name.

6481-2. (*Mr. Lumley Smith.*) Has the spit which is close up at Erith at Coldharbour Point been removed?—That was removed to a very considerable extent between 1832 and 1861. A great number of sand dredgers were licensed by the Trinity Board to remove that shoal. I cannot see myself in what way the removal of that shoal is to cause an accumulation at Erith.

6483. Would it be at all likely to cause slack water there?—I cannot see it. The ebb stream comes fairly down Erith Reach and runs down clear of that shoal and turns round the Point. But after that shoal at Coldharbour Point, that I have just given evidence about, was removed between 1832 and 1861, the water had actually deepened at Erith.

6484. Then as a matter of fact the greater part of this shoal had been removed before the outfalls were opened?—Yes, long before. It was not until after the outfalls were opened and the water was muddy that this deposit formed.

6485. I think in the year 1856 you caused some experiments with floats to be made for the purpose of observing the strength and the direction of the tides?—I made some experiments by order of the First Commissioner of Works.

6486. I believe those were made by direction of the Commissioners of the Admiralty?—Not by direction of the Commissioners of the Admiralty, but by permission of the Commissioners of the Admiralty asked by the First Commissioner of Works.

6487. That was Sir Benjamin Hall, I believe?—It was.

6488. Will you tell me how you came to be directed to make those experiments?—I was employed by permission of the Admiralty under the orders of Sir Benjamin Hall in 1856 for the purpose of examining this river from Putney all the way down to Woolwich, specially with reference to new Westminster bridge and its foundations.

6489. I believe Mr. Bazalgette had furnished you with the experiments made in 1851?—He did, with the experiments made by Mr. Frank Forster.

6490. Those are the experiments which Mr. Phillips spoke about to-day?—Yes.

6491. (*Mr. Bidder.*) Did you report to the Metropolitan Board of Works?—No, to Sir Benjamin Hall, the First Commissioner of Works.

(*Mr. Lumley Smith.*) The report is dated the 30th June 1856, and it is printed in the Report of the Metropolitan Board of Works for 1856. It is as follows:—

"Sir,

"In compliance with orders from my Lords Commissioners of the Admiralty that I should make observations in the tidal stream in the river Thames with reference to former observations made in 1851 at the instance of the Metropolitan Commissioners of Sewers; and further for your information having done so, I beg to lay before you the result of my experiments.

"Mr. Bazalgette (Engineer to the Metropolitan Commission of Sewers) having furnished me with the experiments made in the tidal stream in 1851, I have been enabled to compare my own observations with them, and can bear testimony to the great similarity the results bear to each other. For instance in 1851 for several tides before and after the new moon on June 29th, their float having passed Barking Creek opposite Plumstead Marshes from 2 to 2½ hours before high water, was carried by the stream as far up as the West India Docks, and in one instance as far as Greenwich.

"In my observations with the object in view to ascertain how far the stream extended which passed Barking Creek at two hours before high water there, I found that for two days before the full moon, June 18th, 1856, the stream stopped and turned at the City Canal and West India Dock entrance; on June 18th, it stopped at about 100 yards below or east of the West India Docks; continuing the observations on the ebb it was found to drift to Purfleet Lower Wharf, repassing Barking Creek at 3 hours 22 minutes after high water, thereby verifying the former observations in 1851, which were made at a similar period with reference to the moon's age.

"My further observations were made near the last quarter of the moon, or during the time of neap tides, when I found the stream considerably diminished, the volume of water passing Barking at two hours before high water being carried only as far as Hook Ness. There do not appear to be any observations made in 1851 with which I can make a comparison.

"In concluding my remarks on these observations I may venture to state from my own local knowledge of the river after being many years employed on it surveying, that I consider they have been taken with much care and reported with fidelity.

"I would now beg to remark upon the set and velocity of the main body of the stream on its passage from Plumstead Marshes opposite Barking Creek during the last two hours of the flood, and further, as far as my observations have informed me.

"In the first place the stream at two hours before high water at Barking Creek, or 35 minutes before high water at London Bridge, sets from the upper part of Barking Reach towards the house on the north shore called Duval's House, the main body being one-third nearer the Essex shore; from this position (off Duval's House) it sets directly for the eastern or lower part of the Royal Arsenal, there being a slack stream along the south-east shore of Gallions Reach from the east end of the Arsenal off the canal and along the shore forming the east side of this reach.

"At this position near the Royal Arsenal the main body of the stream with all matter held in suspension, would be set on the flood tide, whilst that portion which is set towards the canal on the eastern shore, would be kept in or near that position until carried away by the ebb tide.

"From the Arsenal the main portion of the flood stream occupies that part of the Reach which washes the shore at the town of Woolwich, running with considerable strength by Roff's Pier and Hog Lane, setting mainly along the line of moorings off the Royal Dockyard, close to which a vast quantity of silt accumulates from local causes on both streams.

"On the north shore opposite Woolwich the flood stream is not so strong, and close to the North Woolwich Pier, and on either side of it, there is an eddy on the flood. From the Royal Dockyard upwards the main body of the flood stream takes a mid-channel course until it reaches the Victoria Docks, when it sets bodily towards the East India Docks, Blackwall Pier, and the West India Docks; this is on the average the extreme western limit that sewage would atttain during a week of springs, if started into the river at Plumstead Marshes opposite Barking Creek at two hours before high water; during the week of neap tides, it would extend only as far as Hookness, much always depending upon the quantity of Freshes after heavy rains, which tend to impede the flood and accelerate the ebb.

The velocity of the stream at springs was found to be as follows: from two to one hour before high water, 2·7 miles (statute) per hour; from one hour before until the time of high water, 1·9 miles; from high water at Barking until the stream slacks at Blackwall it runs about 35 minutes longer and three quarters of a mile further. During the neaps a diminution of the above velocities takes place of about one-third of the above.

"The ebb tide from Blackwall ran down to Purfleet Lower Wharf on the day of full moon a distance of 12½ miles. The ebb tide from Barking Creek starting at high water slack two days after full moon ran down 14 miles, or to Pitcher's Building Yard at Northfleet, thus giving the eastern extent of sewage (started at high water slack off Barking) at Northfleet, and the western extent (as started two hours before high water) at the City Canal or West India

*Capt. E. Burstal, R.N.*

6 Dec. 1882.

Docks as remarked before. These refer to ordinary springs.

"The neaps will be as follows:—The ebb tide from Barking Creek starting at high water slack two days after quarter moon or neap tides, reached Grays, a distance of 11¾ miles, thus giving the eastern extent of sewage (started at high water, Barking), at Grays, and the western extent (as started two hours before high water), at the upper part of Woolwich Reach.

"Excepting in such instances as that of June 26th, when the wind comes suddenly from the north-west, there is always a longer duration of the flood stream and a greater rise of tide than under ordinary circumstances. The contrary will take place with strong southerly winds, the ebb streaming longer and the water falling lower.

"In concluding my remarks, I beg to call your attention to the accompanying table, which contains a detailed account of the observations I have made," then the table is appended.

6492. (*Chairman.*) Are those facts and views in your opinion, correct now?—They were quite correct then, and I have no reason to alter my views of the set of the stream now.*

6493. (*Mr. Lumley Smith.*) The table which is appended to that report, I believe, contains the result of the observation of the stream in June 1856?—It does.

*The annexed table was handed in.*
(*See* Appendix C.)

6494. Has the causeway at Erith been lengthened more than once, to your knowledge?—Not that I know of.

6495. I believe that first there was a floating barge put there?—There was a floating causeway put at the end of it kept down by chains, but I do not remember any other. A long petition came from the Erith people, a copy of which you have, and all the proceedings of the Board in reference to it, engineer's report and all.

6496. In 1882 did you have experiments made as to the drifts of the tide from Halfway House Point or Leather Bottle Point?—I made them myself. I gave evidence about them just now.

6497. Are you speaking now of those that were made in July 1882?—Yes; I made them with the harbour master on board the vessel, because I was anxious to know whether that stream ran with any force down the south side of the channel in consequence of the removal of the spits.

6498. You have more practical knowledge of the subject than I have; you think you have given us sufficiently the result of your experiments?—I think so.

6499. I believe you have the notes made by you on the stream drifts in the Thames on the 14th of July this year?—Yes.

6500. Will you hand that in?—

*The witness handed in the following paper.*

"Stream Drifts from Barking Creek down on the first of the ebb, July 14th 1882, strong wind S.W. High water at 1.0 P.M.

"Put drift pole into river close to buoy, inshore close outside northern outfall.

"This drifted close along shore at Barking Creek down to False Point (northern side of Barking Reach) thence set outwards towards the middle of the river, and towards Kent shore, passing Leather Bottle Point, Halfway House about one-third river over from the southern shore—thence it set over towards the northern side of Halfway Reach and drifted down through the northern or deepwater channel, and was taken up at 2.50 P.M. in the channel below Dagenham Jetty.

"Course of three sets of drifts from Halfway House Point or Leather Bottle Point, July 14th 1882:

"First drift started 2h. 10m. P.M. 1h. 10m. after high water.

"Quarter over from (No. 1) Ice House 39° 20′, High chimney 103° 50′, Magazine Jetty, south side.

"Halfway House (No. 2), 2h. 25m., Ice House 86° 30′. High chimney 78° 30′ Barking Reach.

"Point (No. 3), Magazine Jetty 73° 30′, High chimney 62° 0′, Halfway House.

"Jenningtree Point about 350 feet off Dagenham Jetty.

"Velocity of current 2¾ miles an hour.

"Second drift started 2h. 15m.

"Half Channel over (No. 1), Ice House 39° 30, High chimney 87° 0′, South Magazine.

"Opposite Halfway House Point (No. 2), 2h. 28m., Magazine Jetty 60° 50′, 59° 0′ Halfway House.

"Jenningtree Point. This drift comes close inshore in line 300 feet above Dagenham Jetty.

"Velocity of current 2¾ miles an hour.

"3rd Drift. Three-quarter channel over from Halfway House Point 1h. 20m. after high water.

"2h. 17m. P.M. Ice house 41′ 0″, High chimney 15° 30′, Halfway House.

"2h. 31m. P.M. This drift pole was set over to a point about 700 feet above Dagenham Jetty and was close to the ground.

"Stream drift from a point 100 feet outside low-water mark at Leather Bottle Point, about 1,000 feet above Halfway House.

"Commencing at 3h. 10m. P.M. or 2½h. after high water.

"3h. 10m. P.M. Stream pole, submerged 7 feet, over 100 feet outside low-water mark, or 150 from River wall.

"3h. 15m. P.M. Drifting parallel with round of point about 500 feet off the upper corner of the wall of outfall works.

"3h. 20m. P.M. Ice House 112° 10′, Chimney 109° 30′, Halfway House drifting over the inner part or little south of Mud Bank.

"Velocity of current 2½ miles per hour.

"No time taken. Ice house 72° 20′, Powder Jetty 99° 20′, High chimney.

"3h. 32m. P.M. High chimney 95° 30′, Ice House 106° 0′, Powder Jetty, Jenningtree Point.

"3h. 36m. P.M. Drift pole setting nearly parallel to shore and about 500 feet from high-water mark.

"3h. 39m. P.M. High chimney 61° 50′, Ice House 132° 10′, Powder Jetty, Jenningtree Point, 500 feet off corner river wall below magazine."

"N.B.—The velocity of the current calculated by the time and length of this drift along the south shore close in from Leather Bottle Point is 2½ miles per hour."

Cross-examined by Mr. Bidder.

6501. You have given some evidence with reference to the accumulation of mud in Erith Bight, and, as I understand, your suggestion is that that is caused by the sewers?—It is caused by the dirty water from the sewers. That is my opinion.

6502. I want to get this very clearly before the Commission. You are the Secretary of the Thames Conservancy?—Yes.

6503. And you have taken an active part in the management of their business for some years past?—Yes, as far as my duty is concerned; but not in the management of it.

6504. You were consulted and were engaged in the late arbitration which took place between the Con-

* Captain Burstal afterwards gave in a subsequent letter to Sir Benjamin Hall, dated 18th November 1856. A copy of this is printed in Appendix L.

servators and the Metropolitan Board of Works?—Yes, I gave evidence.

6505. That arbitration taking place at the instance of the Conservators?—Yes, originally.

6506. Who had under one of the Metropolitan Acts, the right to require the Metropolitan Board of Works to remove any mud banks which had been caused by the sewage?—That was the origin of it.

6507. And therefore the subject matter between you and the Metropolitan Board of Works in that arbitration was what mud banks?

(*Chairman.*) Surely that will appear from the arbitration.

(*Mr. Bidder.*) The arbitration is not referred to the Commission.

(*Chairman.*) The submission was surely in writing, or in print.

(*Mr. Bidder.*) No, it was not; it is an arbitration under an Act of Parliament.

(*Chairman.*) Then the Act of Parliament will show what the submission was.

(*Mr. Bidder.*) I am asking the leading witness, and the manager of the business on the part of the Conservators, so as to bring the matter concisely before the Commission.

(*Chairman.*) Any material facts you are entitled to bring before us, but you are reciting the contents of an Act of Parliament, and the submission to arbitration, and you are going to found some question to the witness upon that. Your reciting it does not bring the matter before us.

6508. (*Mr. Bidder.*) It brings the matter to your attention, and it is agreed between the witness and me that I am correctly representing the subject-matter of it. (*To the witness.*) On that occasion you submitted, did you not, to the consideration of the arbitrators, these mud banks which you were prepared to charge against the Metropolitan Board of Works as being caused by them?—No, none of the mud banks at Erith were mentioned at the arbitration.

6509. Is it not the fact that you, having required, as you had the power to do, an arbitration to be held ——

(*Chairman.*) You want to press upon our notice certain facts about an arbitration. Surely, the way in which we can take notice of that is by your putting in the arbitration. If you will ask the witness what he said on that occasion you are entitled to do that.

6510. (*Mr. Bidder, to the witness.*) Is it not the fact that upon that arbitration the only banks of the River Thames in respect of which you sought to fix us with a liability were the three banks at Dagenham, and Crossness, and Margaretness?—They were the only three banks elected by the conservators to go before the arbitrators. I had nothing whatever to do with the question of how many mud banks were before the arbitrators.

(*Chairman.*) That shows the great importance of our seeing what the submission was and what the award was.

(*Mr. Bidder.*) It was a power to take us to arbitration under an Act of Parliament. It was not a submission in the ordinary sense. The Act of Parliament gave them the right in case they were of opinion that we were causing mud banks in the river, and so obstructing the navigation, to require their removal, and if there was a dispute as to the fact, to take us to arbitration. The arbitration did not proceed on any definite issue as to any particular mud banks; but we came before the arbitrator, and the Conservators were in a position to charge us with any mud banks they thought fit.

(*Witness.*) What I said was this: that the only banks that were dealt with by me in evidence before the arbitrators, and the only banks that the conservators elected to have dealt with by the arbitrators, were the mud banks immediately in connexion with the outfalls in Barking and Halfway Reaches; and the Erith question was never gone into at all.

6511. But you know perfectly well that at that time when you came before the arbitrators it was open to the Conservators to have charged us with any banks that they chose?—If it had been so, even at the present time, the mud bank that the Erith people complain so very much about, is not any serious obstruction to the navigation.

6512. You have always considered that it obstructed the navigation, have you not?—No, you never heard me say a word about Erith until to day.

6513. I am not asking whether you said anything about Erith. You have represented to-day, have you not, that that bank has silted up the causeway, and interfered with people landing from ships?—Yes, I have said that.

6514. And in the same way has interfered with the causeway of the Corinthian Yacht Club?—Yes.

6515. Therefore it is in your judgment an interference with the navigation?—I do not know that that was known to me at that time; at any rate it did not occur to me when it went before the arbitrators, and I do not think it occurred to the Conservators at the time that it was worth their while to go into that question.

6516. You will agree with me that it was optional then with the Conservators if they pleased to bring the question before those arbitrators, whether this mud bank was caused by this outfall or not; but they did not do it?—It was quite competent for them to do so, but as they did not think proper to do so, I did not trouble myself about it—and I only do it now because the Erith people have complained of the mud, and they have asked me if I would look up the question, and I have looked it up, and I have given my evidence.

6517. My learned friend, Mr. Lumley Smith, asked you with reference to that spit near Coldharbour Point, opposite Erith Bight?—Yes, what you used to call Rand's Hill, is it not?

6518. Very likely I have called it by a wrong name, but you know the point?—I know the point, and I know the shoal.

6519. You said that that had been partially removed between 1832 and 1861; is it not a fact that a great portion of it has been removed since 1864?—I do not think so.

6520. Are you aware that dredging has been going on in that part of the river to a very considerable extent since the outfalls were open?—No, I am almost sure that it is not so. That the Rand's Hill has been dredged in that time I am ready to admit, and I know of that.

5521. Rands' Hill being as you say a little lower down the river?—Yes.

6522. And also towards the north shore?—No, it is as near mid-channel as possible.

6523. Can you tell me whether the sectional area of the river at that place is not greater now than it was before the outfalls were opened?—I have never measured the sectional area. I have never taken any cross sections. All I know is that a great shoal in the middle ground was taken away, which has very much improved the navigation. I do not believe much in these sectional area questions.

6524. You had charts of this part in 1878 and 1879, had you not?—In 1879, I think.

6525. Have you got those charts?—Yes, they are here.

6526. Could you let us have them?—Certainly.

6527. I suppose you know enough of the engineering question to know that the question of whether the sectional area of the river has been increased, or diminished, is a very important one?—Whatever alteration of the sectional area there may have been, it must have been a very small one, taking the whole breadth of the river. I know it cannot be very much, because I know the general breadth of the river, and the shoals that have been removed would not admit of a very great variation in the sectional area.

6528. You understand that if you deepen and enlarge the sectional area of this northern channel which is on the convex side of the bend, it necessarily has the effect of attracting the tide and the stream to

that side?—I do not see that any alteration which has taken place during 30 years in Erith Reach would cause this accumulation altogether in two or three or four years. All this mud has grown up in a very few years, and during all these 30 years the deepening has taken place in Erith Reach, that is to say, between Erith and Jenuingtree Point. The sectional area might have been enlarged as you say, but no deposit whatever has taken place at Erith; on the contrary there has been a considerable deepening in Erith Bight, and that can be shown by the sections.

6529. You have not yet answered my question as to the effect of enlarging the sectional area?—I cannot answer your question. I am not an engineer.

6530. You have made one statement that this mud bank has grown up in a very few years?—Yes, since the outfalls have been opened, and the water has been of a thick muddy character, which will, when it gets into slack water, deposit silt; whereas in former years, when it was clean water, there was nothing to deposit.

6531. Do you say that the water was clean water in former years?—It was very clean water when I was so much on it in 1833.

6532. Did you not yourself give evidence that the muddy state of it was frightful?—When?

6533. In 1866?—What part of the river was that in?

6534. I think it was before the Rivers Pollution Commission?—That had not reference to Erith, I am sure.

6535. Do you recollect being asked this question, "Was the Thames ever a very bright stream?" and your answer is "If you mean pellucid, I should think "not; but there is no doubt about this, that it was "far clearer before steamers were invented than it "has been since. It is the steamers that stir the "shore up. If you go down the river and watch "the action of a wave made by a paddle-wheel "steamer, it is something frightful. It will tear "away large masses as large as this table from the "saltings, and the rebound mashes up the muddy "portions of it, at least it mixes up the muddy "portions with the water and makes the water "turbid?"—I have no doubt that I did give that answer; but with reference to that I may be allowed to remark that if the paddle wheels of steamers made such a swell as to break off the banks of the river (which they did occasionally, doubtless,) the mud that is made by the earth mashed up, by the breaking off in that way, is nothing like the sort of mud that is to be found in these reaches now.

6536. The saltings that you spoke of are the marshy foreshore down in the neighbourhood of Erith, both above and below Erith, are they not?—I do know what I was alluding to at that place. I know the whole river very well, and I know that there was a considerable degradation of the saltings in some places by the washing of the paddle-wheels.

6537. Where are the saltings principally?—I can tell you all of them, if you like, beginning at Greenwich, and going to Greenhithe and Yantlet and Canvey Island. A great number of them have been stone pitched.

6538. (*Chairman.*) What do you mean by the saltings?—The saltings are the green swards that lie between the back river walls, and where the bank goes off steep and forms a foreshore, on which saltings thousands of cattle feed during neap tides, and they are driven off during spring tides.

6539. (*Mr. Bidder.*) They are called saltings because the high water impregnates them to a certain extent with salt?—Yes, and the cattle like it.

6540. That was, according to your experience, the old condition of the river before these outfalls were opened, that the steamers lashed up the water and tore away masses of the saltings as big as the table, and then churned them up with the muddy portions, and so produced that turbid condition of the river?—No doubt that was so to some extent.

6541. That always has been so since steamers have been going up and down the river, has it not?—Yes.

6542. And always will be so?—I do not know.

6543. (*Chairman.*) Do the screw steamers turn up the water in the same way as the paddle steamers?—The screw steamers do not make such undulations, but when they come up Halfway Reach, where a new shoal is formed a mile long, on the young flood, they churn up that mud, and it brings the muddy portion of that shoal up to the flood tide, and that makes shoals on the flood.

The witness withdrew.

Adjourned to Tuesday next at half-past 12 o'clock.

---

# TWELFTH DAY.

## Tuesday, 12th December 1882.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.

(*Chairman.*) A question was put to Captain Burstal with respect to what he had done, or had not done, before a certain arbitration. I have looked at that arbitration, and I find that it amounts to this: under one of the sections of the Thames Conservancy Act, the Metropolitan Board of Works and the Conservancy Board were directed to refer to arbitration any differences that might arise either as to any acts done by the Metropolitan Board of Works with respect to the origin of any mud banks, or as to their being an obstruction to the navigation. Differences did arise, and two gentlemen of great eminence were appointed arbitrators between the parties, and those differences were at once carefully laid down and limited for the consideration of the arbitrators, in three propositions. The first was, what was the origin of three particular banks at Margaretness, at Barking, and at Crossness? Secondly, were those banks an obstruction to the navigation of the river? Then there was a third negative proposition, that the pollution of the river by sewage as a sanitary question should not be gone into. Then the arbitrators came to certain findings.

We need not enter into what those findings were, inasmuch as they have no bearing upon our inquiry.

(*Mr. Bidder.*) You have, Sir, if you will allow me to say so, stated it very nearly accurately, except in one or two minor particulars. The arbitration proceeded in the way you have described under that Act before the arbitrators and an umpire appointed by themselves, Sir Charles Hartley. Speaking from recollection, I think you will find that previously to their meeting in the arbitration, there was no limitation whatever of the question. The question raised was the liability of the Metropolitan Board of Works in respect of mud banks caused by them, and I might say generally, and in the earlier stages of the case, before it came before the arbitrators, there were certain statements and reports to the Conservators published, in which was shadowed out a case charging the Metropolitan Board of Works with nearly all the mud banks up and down the river. There was nothing in the nature of pleadings or of limitation before we came before the arbitrators. But what happened when we did come before the arbitrators was that my learned friend, Mr. Pope, who opened the case, said that he intended to direct his evidence to those three banks, which you, Sir, have mentioned. He said, "There are other "banks; I do not definitely withdraw them, but you "probably will not hear much about them." In fact, he elected to win upon those three banks.

(*Chairman.*) But after all, the question is what the arbitrators had before them. Surely I have stated correctly what the point before the arbitrators was.

(*Mr. Bidder.*) Ultimately it resolved itself, as you have stated, into the question whether the three banks were caused by the sewage outfalls, and whether they were an interference with the navigation; and you are quite correct in saying that the question of river pollution was not before those arbitrators in any way whatever. But the question whether those banks were caused by the sewage outfalls was a question before them. Of course I entirely agree that this Commission are not stopped, and cannot be stopped, by anything took place upon another occasion. At the same time, I thought it right that the Commission should know, (because probably you have no desire to take more upon your shoulders than you have, which is enough at any rate) that that question as to whether the sewers had produced an actual physical accumulation of mud in certain parts of the river, had been, I think I may say, most exhaustively threshed out before a very competent tribunal, and the result was an unanimous decision in favour of the Board. Further than that I do not wish to carry it.

(*Chairman.*) So far from its being an estoppel, if the question was identical, I should look upon this as a new trial.

(*Mr. Bidder.*) No doubt, and a new trial under circumstances under which one would hardly expect it ought to have been granted, as the award was the unanimous verdict of very highly competent judges. As regards the particular bank in Erith bight, it was referred to, but it was not followed up. In point of fact, the question was the same as regards all four. If you have the report before you, perhaps you will allow me to read one passage from the opening speech. My learned friend, Mr. Pope, who opened the case for the Conservancy, said, "If you will kindly look "upon the cartoon upon your right, it shows three "main banks, one immediately opposite the southern "outfall, one in slack water a little seaward of "Barking Creek, and a third, not so large but "increasing and in course of formation, on the oppo-"site side of Barking Creek by Margaretness, and "the Conservancy allege that those three banks have "been caused by the outfall of the sewage from the "northern and southern outfalls. I propose in the "course of this inquiry, mainly to direct your at-"tention to the question of these banks." Those were the three banks as to which they had the strongest case, and they felt that if they could win upon any, it was upon those, and of course we feel that it is a little hard, after we have beaten them upon their strongest horse, to have the same horse brought out of their stable again.

Captain Edward Burstal, R.N., re-called.

Further cross-examined by Mr. Bidder.

6544. I was cross-examining you with reference to your evidence in 1866. You have known the river for a great many years. The condition of the river was very bad before the outfalls were opened, was it not?—The condition of the river in the neighbourhood of London was very bad.

6545. And all the way down to Barking?—Not that I am aware of. I know it was very bad all about London, and, probably, I should say, from Greenwich, beyond where we are now.

6546. It always has been and almost must be a muddy river; is not that so?—That depends upon what sort of mud it is. No doubt there always has been a quantity of mud in the river; I do not know whether there always will be or not; but when I knew the river first I can conscientiously say that there was very little mud floating about in the lower part of the river, or, in fact, all over the river. The sewage has been poured into the river since, I think, 1845, and since that the river has become filthy. In 1857, 1858, and 1859, and so on, the upper part of the river was in a most horrible state in the neighbourhood of the metropolis.

6547. But, apart from any question of the effect of sewage either before or after the opening of the outfalls, have there not always, according to your long experience and observation, been, in all parts of the river, large quantities of mud stirred up, as you described in the answer which I read to you, by the steamers, swept up the river by the in-coming tide, and deposited all the way up the river even as far up as Richmond?—No doubt there was a quantity of mud, and there always has been a quantity of mud floating about in the water of the river.

6548. I see, in 1866, before the Commissioners, you were asked this question: "We have had it "stated in evidence that the in-flowing tide takes up "vast quantities of mud, and deposits it upon the "shoals and banks below Richmond?" and your answer then (and you will probably give the same answer now) was "No doubt that is so. The shores "of the river are muddy, and are stirred up by the "action of the steamers; the consequence is that "the water is made turbid, the stream carries it up "the river, and then, at slack water, where there "are no steamers, mud is deposited." Do you agree with that now?—No doubt it was so.

6549. Then, I see you also describe the condition of the river in 1856 and 1857 as being most filthy; that you adhere to still?—Yes, I said that just now.

6550. Then you went on further to say: "The "whole contents of the sewers went into it, and "then the sewage oscillated up and down, passing "London?"—Yes, that was so.

6551. "The river there had not the same power as "at Barking Creek to carry it to the sea;" is that so?—I do not quite know what that was, but I know this, if I may be allowed to make the remark, that then, as now, the stream would flow from the upper part of the river down, probably, to Greenwich, and then the next flood would come and meet it, and carry it back again; and I think that the oscillation that I referred to there must have been the oscillation of the river water that began to get polluted at a certain period of the ebb tide, when the flaps of the sewers began to get opened, and the sewage water ran into the river; and the consequence was that the stream had not time to carry the water, then polluted,

very far down the river, before it was met by the flood tide.

6552. Of course it is a long time ago, and your memory, like that of the rest of us, has limits to its capacity, and therefore I am endeavouring to refresh it. The purport of your evidence then, I take it, was this: if sewage were poured in at Barking, according to the experiments which you made, and which you gave us the other day, it would be carried out to sea at the rate of five miles a fortnight?—That was the conclusion I came to.

6553. But, on the other hand, you said that, under the then existing state of things, when sewage was put in here in the metropolis, it did not get carried out to sea at all, but oscillated up and down in the river?—I cannot say that none of it would go to sea at all; but the main body of the water in the metropolis, that is to say, from Chiswick, and all the way to Richmond, went floating up and down, and getting charged every 12 hours with the stuff from the sewers.

6554. It would be fair to you if I read the whole of your answer. The question was No. 9,080: "But, "before intercepting sewers were formed, the river "had the appearance of a foul stream?" and your answer was "Yes; when I was employed on the "survey in 1856 and 1857 the river was in a most "filthy state. The whole contents of the sewers "went into it, and then the sewage oscillated up and "down, passing London. The river there had not "the same power as at Barking Creek to carry it to "the sea. I made other experiments that were never "reported upon. I found, when the river was in a "normal state, that if I put floats in at high water at "Waterloo Bridge, they would go a certain distance "down the river on an ebb tide, and with the next "flood tide would come up to Waterloo Bridge again. "The sewage would be oscillating up and down "within the metropolis, I have no doubt, for "months?"—That is exactly the same as the answer I gave just now.

(*Chairman.*) What is the date of that opinion?

(*Mr. Bidder.*) That was given on the 7th of February 1866, before the Royal Commission appointed to inquire into the best means of remedying the pollution of rivers.

(*Mr. Michael.*) Mr. Rawlinson, Professor Way, and Mr. J. T. Harrison, were the members of that Commission.

(*Mr. Bidder to the witness.*) Then I see you were asked, "How far up the Thames would sewage, dis- "charged in the neighbourhood of Barking Creek at "low water, reach?" and your answer is, "It never "ought to be discharged at low water; and I believe "that the only reason for its being so discharged is "because the works were not sufficiently advanced. "I think there is no discharge now at low water."

6555. If discharged at low water, how far would the sewage reach up the Thames?—To Vauxhall Bridge.

6556. (*Chairman.*) What is the velocity of the inward flow?—On the average $2\frac{1}{2}$ miles an hour.

6557. And the ebb outflow?—Probably $2\frac{3}{4}$ and a little more.

6558. "(*Professor Way.*) The reservoirs, I believe, "are made of such a capacity as to hold the whole of "the sewage during a certain time? (*A.*) I believe so. "The sewage should be discharged at a given time, "just before or not far from high water. It might "then find its way a little way up to Woolwich, but "the next ebb tide would take it away and it would "never be seen again." Do you still adhere to the views which you then expressed?—I do not adhere to that last paragraph which you have just read, in which I say that it would never be seen again. That was a sort of *façon de parler* more than anything else; it would have been ridiculous if I had said such a thing as that in its literal meaning, because I knew at that time, and I showed by my own observations of the flow of the stream, that the floats, which, if I may be allowed to say so, represented the water in which they were placed, started away on the first of the ebb from Barking; and, if I remember rightly, on a spring tide they went a certain distance down the river, and they returned and went further up the river than Barking, sometimes as far as Blackwall. Therefore, if the water in which those floats were then put remained charged with sewage in its contaminated state, the answer that I gave at that time could not be said to be literally correct.

6559. (*Mr. Abernethy.*) May I ask whether, when you gave the answer which the learned counsel has just read to you, it was under the impression that the sewage was to be discharged on the ebb tide and the ebb tide only?—Yes, at high water.

6560. (*Mr. Bidder.*) A little before and a little after high water. I always like to be fair with a witness, and it is only fair that I should read to you your next answer, in which you said that you would much rather see the sewage discharged further seaward?—I think it would have been better if it has been discharged lower down, and discharged in a part of the river where there was a stronger stream to carry it away.

6561. You gave further evidence as to the effect of the malaria from the river upon persons living by the river, and upon the men who worked upon the river, in producing sickness and even peculiar diseases which were specially treated at the hospital?—I remember very well all the circumstances connected with that, and if you want me to repeat them from memory, I will do so with pleasure.

6562. It is a fact that the condition of the river was such that the malaria produced vomiting and sickness in those who worked upon the river, and upon yourself amongst others, and a peculiar affection of the mucous membrane as you described?—That is quite true.

6563. Then taking another answer which you gave with regard to the mud, you pointed out that a very considerable supply of mud was drawn from below these outfalls at a place called Northfleet, and in that neighbourhood?—The mud coming into the river from near Northfleet was what broke off from the saltings.

6564. But you evidently considered that at that time to be a very important source, because you were asked by Professor Way, at question 9121: "As to "the pellucidity of the river. From what you have "said, I infer that as there is really no bringing up "of matter from below, but merely the stirring up of "that which already exists, tidal action ought, after "a time, to rid us of the mud? (*A.*) There will be "a large quantity of fresh water constantly going "down, and there will not be muddy water coming "up. I believe that the water of London will be "cleaner than any man alive has ever seen it. "(*Q.*) Do the steamers produce mud from the bed "of the river, or merely stir up that which has "already come down? (*A.*) They produce it; they "break off the banks. (*Q.*) I mean above bridge? "(*A.*) No, I think they merely stir up what is there. "(*Q.*) Then we ought to get rid of it, ought we "not? (*A.*) No, for this reason, you get a fresh "supply from below. There is a place at North- "fleet where the waves from the steamers strike "against the banks and break them away and thus "form mud. (*Q.*) That mud would not come further than London Bridge? (*A.*) Yes, it would?" —Yes, I should think that is quite correct. I do not see any reason to alter my opinion as stated then.

6565–9. Another question which I am tempted to ask you is this: It was your observation at that time that the fish had already to a great extent disappeared from the upper parts of the river, was it not?—What do you call the upper parts of the river?

6570. Here, and down at Greenwich and Woolwich?—Yes, I think they had.

6571. Before the outfalls were opened?—Yes, I think it was before the outfalls were opened that the eel schuyts went away.

6572. That is all I have to trouble you with on that evidence. Going to the question of mud and dredging, and the condition of the river in Erith

Bight opposite Erith, is it not the fact that either the Conservators, or the Trinity House, or private dredgers have since the year 1864 dredged very large quantities of material from the river, especially from the northern side of the river, in that part which is opposite Erith?—I do not believe they have—or not since 1864.

6573. You have returns as to the dredging, have you not, in the records of the Conservancy?—No.

6574. You produced certain returns on the last inquiry, did you not?—I do not remember. Mr. Smith, the master of the steamer, had something of the sort.

6575. A statement was put in by a gentleman of the name of Ellis James Smith; is he an officer of yours?—He was; he is dead now.

6576. I think he put it in as purporting to come from your records?—It came from his log-book.

6577. At page 260, there is a table showing the comparative amount of dredgings done in Blackwall Reach and the Rands from 1859 to 1879; and he states that he had been actively employed as commander of the "Conservator" steamer for upwards of 20 years. You have no doubt that that table was prepared from the records of the Conservancy and their officers?—I am quite sure that whatever Mr. Smith put in was correct; but I should like to see what the table was.

6578. It is a table showing the comparative amounts of the dredging for the last 20 years?—He kept it either in his private journal, or else it was put in his log book. Mr. Smith says that he took every day in his book an account of the position of the dredger, and that from those accounts he made out the return.

6579. If you will take the compartment of the river which is headed "Erith Reach," you will see that that table indicates that from the year 1871 onwards a very large amount of dredging was done in that part of the river.

(*Chairman.*) That is, that there were certain dredgers anchored there. That is what this paper shows.

(*Witness.*) I see in 1864 he has a dredger for one month.

6580. (*Mr. Bidder.*) But I referred to the year 1871; there was not very much before 1871?—There is nothing in 1871 at all in the north part of Erith Reach except "three months, Lower Coldharbour."

6581. Erith Reach, off Rainham, in 1871, five on the north side, one on the south?—But that is not Erith Reach.

6582. Off Little Coldharbour, none; off Lower Coldharbour, three on the north side. Then, in 1872, you have one on the north side off Rainham, 12 on the north side off Lower Coldharbour. Then, in 1873, three off Rainham, two off Little Coldharbour, one off Lower Coldharbour. Then, in 1874, 15 off Rainham, and four off Little Coldharbour. Then, in 1875, 15 off Little Coldharbour, and five on the south side. In 1876, 10 off Little Coldharbour, and five off Lower Coldharbour, all on the north side. I will not read them all in detail. Have you any reason to believe that those do not accurately represent, I will not say the quantity, but the extent of the dredging?—I daresay they do. I suppose they were bag and spoon dredgers.

6583. And they were put in on the last arbitration for that purpose?—Not by me; by Mr. Smith. I never saw them.

6584. But they were produced by the Conservators—No doubt.

6585. The last division on that same page gives the dredging off Erith, of Rands Reach?—Yes, that is below.

6586. And that shows generally that a great amount of dredging there took place, beginning in 1862, 1864, and 1865; not quite so much in 1866, in 1867, and so on down to 1871, when it appears to have stopped?—That is when the Rands Hill was taken away. Rands Hill is below Erith.

6587. With regard to these experiments which you made in 1856, there appears to have been some question as to whether Sir Joseph Bazalgette took part in them or not. I believe, in point of fact, you conducted the experiments, and he was present as representing the Metropolitan Board?—No. It was just in this way, in a very few words. Sir Benjamin Hall was the First Commissioner of Works. In 1856 he asked the Metropolitan Board of Works to supply me with a copy of Mr. Frank Forster's tidal experiments in 1851. The object of my making experiments was for the purpose of testing Mr. Frank Forster's experiments for the satisfaction of the First Commissioner of Works, as to the flow and reflow of the stream, in order that he should be satisfied that the sewage that was ejected into the river at a certain point would not flow up to London.

6588. (*Mr. Balfour Browne.*) Those were the experiments spoken to by Mr. Phillips upon the last occasion that the Commission sat?—Yes. I had an interview with Mr. Bazalgette, who was engineer to the Metropolitan Board of Works, and he came to Woolwich and saw me, and I pointed out to him the mode which I intended to adopt in making the experiments, in order to have a fair and honest comparison with the experiments made by Mr. Frank Forster. That is all that Mr. Bazalgette did. He came with me for about an hour, but he never went down the river with me.

6589. (*Mr. Bidder.*) Of course it is some time ago, and I am sure you are speaking to the best of your recollection; but I must ask you to press your memory a little more, because I have in my hands the order of the Metropolitan Board that Mr. Bazalgette should be appointed by the Board to meet Captain Burstal for the purpose of verifying the experiments referred to?—Well, he did meet me, and he was with me for about an hour at Woolwich; and that is all I saw of him and all he saw of me.

6590. I must leave it there till he comes?—I shall be very glad to see him, and to remind him of the hour he passed with me off the Point at Barking Creek. Then he went to Woolwich, and I never saw anything more of him.

6591. Neither you nor Sir Joseph Bazalgette would be anxious to say anything to the detriment of the other; but, apparently, there is some little divergence in your recollections, and I must leave it till he comes to clear it up?—I shall be quite satisfied.

6592. With regard to Erith, a place where you say the mud has been accumulating, is it not the fact that the sectional area of the river at Erith is greater now than it was when the outfalls were opened?—It must be so to some extent, because, as you said just now, dredging has been done there. But what I say is this: that if you dig a great hole in the river you merely make a pond; you do not increase the sectional area in such a manner as to affect any other part on the opposite side of the river. But if you dig a hole in the river, and communicate with that hole from all parts of the river for a long way above, making a gutway into that hole, and an opening from that hole for the water to escape to the lower part of the river, then you will doubtless cause something to happen which will have a tendency to draw the water into that gutway, and into that hole which is dredged; but not otherwise. I have some sections which I only plotted a few days ago, which are quite at your service, by which you will see that dredging has been done at a certain part on the north side, the Essex side, and just above and just below that dredging, the river bed is just where it was many years before; so that I cannot, for the life of me, see that because you dredge a hole or scratch away a few banks on one side of the river, where there are probably eight or nine feet of water, you necessarily create such a divergence of the stream as to cause the other side of the river to be slack.

6593. Do you not see that your reasoning is proceeding a little too rapidly, and that it does not follow that because you have dredged one part of the river, and left the portion above and the portion below as they were before, you have dredged a hole? It may

be that the part of the river you have removed was more contracted and shoaler than the parts above and below, and that you have removed by that particular dredging, at a particular spot, that which to a certain extent diverted the tide previously?—I do not think so. I am prepared to state what I have not stated before, for I did not know it for a fact until this morning, and that is this: that the large middle ground in Erith Reach was removed before 1853.

6594. What do you call the large middle ground?—The large middle ground was about there (*pointing it out*), and the shoal that we have been talking about, off Coldharbour Point, was about there (*pointing to it*). That middle ground was removed before the year 1853, and in 1853 the Trinity Board put their dredgers upon that shoal. I have a little plan that I got from the Trinity House, and I think there will be sufficient evidence to show that a great part of the dredging that was done in Erith Reach was done in 1853 (*producing a plan and describing it*). That is where the large shoal was in Erith Reach. This chart was prepared by the master of the Trinity dredger that was at work there then.

6595. What was the name of the dredger?—I do not know.

6596. Is he a gentleman who is accessible now?—No; he is dead. This chart is "drawn by H. Parker, "master of the 'Goliath' dredger, pursuant to orders "of the supervisors of the Ballast Office." This was lent to me this morning by the Trinity House, and there is the spot where the middle ground was formerly, and, as you see here, it was removed then, and in 1853 they put the dredgers upon the shoal just above Coldharbour Point, so that I presume it was there, perhaps, for a year; I do not know how long. (*The witness handed the plan to Mr. Bidder.*)

6597. The chart, if I follow it rightly, appears to show that what you call the middle ground in Erith Reach, which is a shoal about the middle of the Reach, rather on the south than on the north side, was removed at that time?—Yes, in 1853. It was nearly in the middle of the river.

6598. At any rate it says "worked ground"?—Yes.

6599. It also appears to represent the dredgers as being located just above Coldharbour Point?—Yes.

6600. But it does not show when, subsequently to that time, the dredging was completed?—No, it does not do that. I only produce that plan for what it is worth.

6601. You answered me that you would not deny that the sectional area of the river was increased opposite Erith; is it not also the case that that increase of sectional area has taken place on the northern side?—It must have been so, because the greatest part of the dredging did take place on the northern side.

6602. Do you remember giving evidence before certain other Referees, appointed by the First Commissioner of Her Majesty's Works, in the very same year, 1856?—I was associated with Captain Galton, and some referees there.

6603. With reference to what we were talking about just now, let me draw your attention to the report of what you stated to the Referees then, in which you expressly said that Mr. Bazalgette was present at one of the experiments, which you described, in which you put the float down?—I think I have said just now that Mr. Bazalgette came to Woolwich, and he came off in a boat to me when I started these experiments. I pointed out to him the mode and the time of making these experiments, with which he perfectly agreed; and I am quite sure that if Sir Joseph Bagalzette is in this room now, or if he comes, he will tell you that he never went one yard down the river with me beyond the point.

6604. You said, "Another float put in at Barking "two hours after high water floated down to Long "Reach on the ebb and back as far as Charlton Pier "with the flood. Mr. Bazalgette was present at these "experiments"?—Did I say that?

6605. You are reported in print to have said it?—Just so; but Mr. Bazalgette was not down the river drifting with the drift, and coming back with it; he was only with me when I started, I assure you.

6606. That is what you said about it when it was fresh in your memory?—I am quite certain that Mr. Bazalgette was never with me half an hour in a boat in his life. He came down from Woolwich to Margaretness Point, and he went back. I am certain of it.

6607. It is possible that your recollection within a few days of the occurrence, nearly 30 years ago, may be more accurate than your recollection now?—That is quite possible.

Examined by the Commission.

6608. (*Mr. Abernethy.*) You know various important tidal rivers in this kingdom, I suppose,—the Humber, for example?—I do not know the Humber very well. I have been up it two or three times.

6609. You know that, generally speaking, other tidal rivers are quite as muddy, if not more so, than the Thames?—Yes; so is the Medway.

6610. Do you recollect where the outfalls of the metropolitan drainage were first proposed to be made?—Yes; on Greenwich marshes, I believe.

6611. In 1856 you advised Sir Benjamin Hall upon the subject, did you not?—Yes.

6612. Where did you recommend that the outfalls should be?—I recommended that they should be lower down the river. First of all they were to be at Margaretness; and I said then, that if the sewage was put out at that point, it would reflow and get up to London frequently. Then they went further down into Halfway Reach; and even then I said that they ought to be lower down, at Rainham Creek on one side, if I remember rightly, and at Jenningtree Point on the other.

6613. (*Colonel Ewart.*) One mile above Erith?—About a mile above Erith.

6614. (*Mr. Abernethy.*) You are not aware that it was proposed originally to discharge about half a mile below Mucking lighthouse?—Yes; the Referees proposed that.

6615. And on the south side, four miles below Gravesend?—Yes; near Cliff Creek. That was what the Referees recommended.

6616. (*Colonel Ewart.*) When you gave that opinion, that the points at which the sewage of the metropolis could be discharged without reflowing into the metropolitan area should be not nearer than Rainham Creek on the north side, and one mile above Erith on the south, did you contemplate that it should be discharged under certain conditions?—My opinion was always that it should be discharged at about the time of high water, and that the first set of the ebb stream would take it down as far as it could go, and that then it would reflow up to a certain point and back again, constantly going up and down twice every 24 hours. But I never thought that it would go up so as to pollute the inhabited part of the metropolis, such as Woolwich and Greenwich, and from there upwards. I thought that would be a safe point for starting the sewage from in order not to pollute the river in the neighbourhood of the metropolis.

6617. And provided that it was discharged at certain times?—Of course that is very material.

6618. Did you at that time consider the amount of sewage that was then going to be discharged, or did you look to the future?—I merely considered that the amount of sewage then being discharged would be all the sewage of the metropolis; I never thought of what was going to happen for the future. But

the system to be adopted was to put it into the river, and let it find its way down as far as it could, and then that ultimately the water would find its way to sea, and that the river passing through from Greenwich up here would be freed from all the filth with which it was then polluted.

Re-examined by Mr. LUMLEY SMITH.

6619. As I understand, the chief matter to be discussed before the Referees was whether, if it went to Barking, it would come up and poison London; was that the chief matter?—I did not go into that question before the Referees at all. I took some tidal drifts for them in Sea Reach, and they conferred with me on several occasions; and they came to the conclusion and made a report, that if the sewage was discharged on the south side at Cliff Creek, and on the north side a little below the Mucking lighthouse, they would never know it, even up as far as Gravesend. That I believe was their idea, and I believe it was what they stated.

6620. I see that in the evidence which you gave in 1866, in answer to question No. 9088, you say, "Supposing it possible, I think it would have been "better to have taken the sewage down to Northfleet "about the full end of the flood tide, and then let it "run off as it could, without any tank." You seem to have been then of opinion that it would have been better to take it as far as Northfleet?—I was of opinion, no doubt, that the further they could get it down the river the better; and if it could be put into a settling tank and precipitated, and nothing but fluid passed into the river, it would be very much less objectionable than it has turned out to be.

6621. Then you were asked this question by Mr. Harrison: "Supposing the sewage were dis-"charged 10 miles lower down, what would be the "effect?" and your answer was, "Ten miles lower "down is perhaps rather a short distance. If the "sewage could be always discharged by gravitation "at a point 15 miles lower than Barking Creek, and "allowed to mix with the water of the river, there "would be very little of it seen again." Do you still think so?—Yes; I should think that very reasonable and very fair.

6622. You were asked about the effect of steamers upon the mud, tearing off portions of the saltings; before 1866 were those steamers in full work?—I think it is only fair that the Commissioners should be impressed with one fact respecting steamers, and that is, that in those days we had very large heavy paddle-wheel steamers, paddling up and down the river, which made a much heavier sea, and disturbed the banks a very great deal more than the screw steamers do at present. You will have a screw steamer going along at present at a very quick pace making very little wave; nothing to be compared to the wave that the old paddle-wheel steamers used to make.

6623. Then, so far as the muddiness of the water is concerned, it would be less likely to result from the action of steamers now than it was before 1866?—I should think so. I do not think there are such heavy waves sent upon the banks as there used to be.

6624. But when you had those paddle-wheel steamers did you find the river in the same dirty, muddy condition that you do now?—Certainly not. Then it was really healthy mud; now it is filthy black mud. I have not been on the river very much of late years; but anyone who goes on the river and sees the character and colour of the water down from Woolwich to Greenhithe must know very well that that is not the colour that the river water used to be.

6625. Then I see that my learned friend asked you a question or two about what you said in 1866, as to the effect of the water in London on health. I see you mention that in 1858 and 1859, when the river was in a bad state, there was very little sickness on the river; do you remember that?—I do not believe there was much.

6626. 1858 and 1859 were bad years, were they not?—Yes, they were bad years; the river stunk most abominably.

6627. Did you find much illness amongst piermen and bargemen and Custom House officers?—No; I believe there was not much.

6628. I see you were asked, "May I take your "opinion to be that, although a river is very foul to "sight and very noxious to smell, it does only a "minimum mischief to health?" and you said "Yes" to that?—Yes.

6629. On the other hand, you have known cases of illness; you yourself have suffered?—When I was surveying the river I was generally at work at low water, when the river was very much charged with filth, and I was made sick with it; and many of the men on board the "Citizen" steamers were attended on by a nephew of mine, a Mr. Ord, who was house surgeon at St. Thomas' Hospital. He has told me that frequently. That was somewhere about the year 1856. As far as I was concerned it was very nauseous, and I very often had a sore mouth, and all the mucous membrane of my lips and mouth made bad by the offensive smell of the river.

6630. A word or two about this dredging. This table that my learned friend has drawn attention to was not prepared by you, as I understand?—No, it was prepared by the master of the steamer.

6631. You were going to tell us something about the spoon-and-bag dredgers, were you not?—I said, I thought they must have been spoon-and-bag dredgers. Most likely the master of the steamer counted the vessels that were working on the river, and they must have been spoon-and-bag dredgers; they could not have so many steam dredgers as that.

6632. Do spoon-and-bag dredgers raise anything like the quantity that the steam dredgers do?—No.

6633. (*Mr. Bidder.*) It is not the number of dredgers, it is the number of months the dredgers were working?—I did not prepare the table myself, and I cannot tell what he meant.

6634. (*Mr. Michael.*) The spoon-and-bag dredgers do not occur in the table at all?—I did not prepare the table, and I cannot hold myself responsible, or the conservators either, for what Mr. Smith said.

6635. (*Mr. Lumley Smith.*) That table does not show whether they were steam dredgers or spoon-and-bag dredgers?—No, I believe not.

6636. There are a great number of spoon-and-bag dredgers at work always, are there not?—There used to be.

(*Mr. Bidder.*) It is clear that these were not spoon-and-bag dredgers, because, if you will look at page 259, he was asked this question: "With regard "to this table which you have made, there is a dis-"tinction between the gravel dredged by hand-"dredging and other dredging? (*A.*) They dredge "for shingle ballast; they do not dredge to clear "the river, but for other purposes. (*Q.*) Have you "any record of the number of sand barges em-"ployed? (*A.*) No. There are barges dredging "with the bag-and-spoon from the bottom, and "others go on the foreshore, and they shovel it up. "(*Q.*) Have you any record of this work? (*A.*) No "record. This table has reference to steam "dredgers."

6637–40. (*Mr. Lumley Smith.*) The spoon-and-bag dredgers are people who dredge for their own profit and sell the gravel?—Yes, they sell the gravel.

6641. Who are the steam dredgers?—The steam dredgers that he refers to are the dredgers belonging to the Trinity House; and I think there were two private dredgers; one was a dredger belonging to Messrs. Hunter and English, and the other to Mr. Williams, I believe.

6642. (*Mr. Abernethy.*) The quantity dredged by the bag-and-spoon would be small, would it not, as compared with the quantity dredged by steam?—It

*Capt. E. Burstal, R.N.*

2 Dec. 1882.

would. A bag-and-spoon dredger would not hold more than 40 or 50 tons.

(*Chairman.*) That table was evidence which, I understand, was handed in by the conservators on a former arbitration, and they give credit to that evidence, and there is that answer of the witness, that that table only refers to steam dredgers.

(*Mr. Lumley Smith.*) That is so.

6643. (*Mr. Bidder to the witness.*) Perhaps you will recollect that you also handed in a return of the licenses which are granted to hand dredgers?—Yes.

6644. I believe the conservators grant licenses, for which a fee is paid?—Yes.

6645. And you have an accurate record of the number of those?—Yes.

6646. Is that (*handing a table to the witness*) the table you handed in?—That is it.

6647. That return came from your office also?—I suppose so. I have not seen it before.

6648. (*Chairman.*) Do you know anything about it?—I do not. It was produced by somebody; I did not receive it.

6649. (*Mr. Lumley Smith.*) Something was said about some contours; have you some contour sections prepared yourself?—No.

6650. (*Mr. Bidder.*) I presume you would have no difficulty in preparing now for the Commission a similar return to that?—No.

6651. Then I ask that that may be done, distinguishing eastward and westward of London Bridge?—Above and below the bridge.

6652. (*Mr. Michael.*) In every year there is a return of the amount received by the Conservancy for licenses granted?—Yes; I will get that return. (*See Appendix B T.*)

6653. (*Mr. Bidder.*) I see that amongst your accounts you have an annual account of the expenses incurred by persons for dredging below bridge. I find 6,021*l.* in your accounts of last year, "By cash, for expenses connected with dredging"?—But that dredging is merely dredging for moorings; I do not think that would be of any value to you at all.

6654. (*Mr. Abernethy.*) In making that return, do you specify the nature of the material dredged?—I am afraid we should not be able to do that.

6655. (*Mr. Bidder.*) I am told that your accounts for the year 1876 show 20,000*l.* expended in dredging. That could not all be for moorings?—I expect that that is more for the cost of new plant. It must have been so; it would include the cost of the dredgers.

(*Chairman.*) I do not see what bearing all this has on the case. We are discussing that one point at Erith.

(*Witness.*) I am sure we could not give you any information as to any quantity that has been dredged in any one particular part of the river, for this reason: a man takes out a license to dredge the river; there are certain conditions on the back of that license, and he can go anywhere he likes from London Bridge down to the Nore. Therefore we could not give you any information whatever respecting the amount taken from any one particular part of the river.

(*Mr. Lumley Smith.*) I understand that some careful sections have been taken of the river. I will take whichever course the Commission like. After Christmas I believe we shall have some careful contour sections that have been prepared, showing the capacity of the river, and so forth; and I can take Captain Burstal's sections with those other sections all at once, if you think that more convenient, or I will examine him upon them now.

(*Chairman.*) Do not let us get into the question of the obstructions of the navigation, because we must steer clear of that.

(*Mr. Lumley Smith.*) Or I can have Captain Burstal's sections handed in, and have them identified now; and my learned friend can see them between this and Christmas, and he can cross-examine about them after Christmas if he wishes.

(*The witness handed in some sections, see Appendices* D., E.)

(*Mr. Bidder.*) Of course these sections, if complete, may be very valuable, but at present they only tell half the story. What I would suggest is, that my learned friend and Captain Burstal should postpone putting them in until after Christmas, and that they should then put them in complete, so that they should show the whole river. At present they only show the south side, and not the north side.

6656. (*Chairman to the witness.*) Are these plans prepared under your superintendence?—Yes.

(*The witness described the plans to the Commission.*)

6657. (*Mr. Bidder.*) In these sections, if I follow you rightly, you have simply shown what has happened on the south side of the river, but you have not continued the sections so as to show what has happened on the north side of the river?—No; my only object in having these sections drawn was to show what has been talked of so much in this room by the Erith people about the deposit of mud at that place. You can have sections made upon the north side just the same.

6658. You know perfectly well that the answer to that suggestion of silting was that the silting was caused by the north side having been deepened?—No, I have never said so.

6659. You know very well that our contention on the last arbitration was, and would be again here, that the south side silted because the north side was deepened?—That does not follow at all, in my opinion.

6660. Will there be any difficulty, before the Commission meet after Christmas, in your completing these plans and sections so that they will show the same thing throughout the bed of the river across at the north side?—We can get a plan of the north side if you like.

6661. Have you the materials?—We have the plan, and the same materials as we had in the other case.

6662. Have you any objection to make the thing complete?—I have no order for anything of the sort; but I beg to say that what I have put in is perfectly complete, because it was done with only one object in view, and that was to show the great changes that have taken place in the bed of the river near to the town of Erith.

(*Chairman.*) You will be able to make your own plans, Mr. Bidder.

(*Mr. Bidder.*) Of course I can, sir; but if you will look at the way this is headed, it is entitled "Cross-" sections showing alterations in the bed of the river "off Erith;" whereas, when you look at it, it only shows the alterations in that part of the bed of the river which is on the south side.

(*Chairman.*) Take it for what it is worth. You will be entitled to make any remark you like upon the evidence; but what you now call upon the witness to do is to undertake the labour and expense of making sections or plans to supply you with additional evidence.

(*Mr. Bidder.*) Why not? He has all the materials.

(*Witness.*) You have the materials also.

(*Chairman.*) You cannot call upon this gentleman to make such sections. These plans are legitimately in evidence. Captain Burstal says that they have been made under his superintendence, and we take them as representing what they purport to represent, and nothing more. It will be open to the learned counsel to point out that they represent nothing; that they represent worse than nothing; that they are, in fact, worse than useless. But I understand Mr. Bidder to call upon the witness to undertake now to prepare for him an additional set of plans.

(*Mr. Bidder.*) Not for me. Remember, sir, that the Commission is here inquiring into a public question of great importance, and Captain Burstal is here as representing a public body, the conservators, who are laying certain materials before the Commission: that public body being those who have charge of the river, and who have peculiar facilities and opportunities for knowing what is going on, and having records of

the condition of the bed of the river, and having the materials ready. Knowing, and telling the Commission that my case will be, as regards this point, that what has happened on the south side is the result of what has happened on the north side, my application is that the Commission will ask that public body, having the materials, to supply them with the whole materials, which are relevant and necessary to decide the question.

(*Chairman.*) If they are materials which you can get by giving them notice to produce them you can give the necessary notice, and we shall see whether they produce them, or not. If they do not produce them, of course it will be open to you to observe upon it. But what I understand you to ask the Commission to do is to require the witness to prepare certain things. We can make no order upon the witness.

(*Mr. Bidder.*) As a Royal Commission you can call upon the conservators to supply the materials necessary for the purpose. They being a public body who have the custody of these records, I ask you to call upon them to supply us with the materials necessary to decide this question.

(*Witness.*) You have the materials yourselves; you have a copy of the chart that I left here last week.

(*Chairman.*) If you have any application to make to the Commission, Mr. Bidder, you can make it in the regular form; but I do not think that we need detain Captain Burstal longer.

(*Witness.*) I have not the power of doing it; I must submit these things to the conservators and get their consent.

(*Mr. Bidder.*) I simply make the application, and I ask you, sir, to call upon the conservators, and use your power to obtain the complete materials with regard to that portion of the river.

(*Chairman.*) The conservators have heard your remarks, and I have no doubt they will pay due attention to them.

The witness withdrew.

Mr. Edwin Hughes called in; examined by Mr. Balfour Browne.

6663. I think you live at Green's End, in Woolwich?—That is my office.

6664. You are solicitor to the Local Board of Health at Woolwich, are you not?—Yes.

6665. And I think you have been requested by that body to give evidence before the Commission?—Yes.

6666. How long have you lived and carried on business in the parish of Woolwich?—Since 1845.

6667. And I think you were a member of the Local Board for about 20 years?—Yes.

6668. That was previously to the time when you became their solicitor?—It was.

6669. I think you were for a time also a member of the Plumstead District Board, and also connected with the Plumstead Vestry?—I am on the Plumstead Board now, and have been for 16 or 17 years.

6670. So that you are very well acquainted with the locality and its sanitary requirements?—Yes. I am chairman of the sanitary committee for Plumstead at the present moment.

6671. I think you have also some connexion with the steamboat company, have you not?—I had formerly.

6672. You know the river very well?—Perfectly.

6673. And you have travelled upon it frequently?—Yes.

6674. Would you tell the Commission what is the condition of the river at Woolwich?—It is very bad in hot weather.

6675. Is it your view that it is getting worse?—Yes; but we have not had any hot weather lately.

6676. In your opinion, and in the opinion of the Board that you represent, what is the cause of this deterioration in the condition of the river?—Because the sewage is emptied at one spot where the outfalls exist.

6677. How is the sewage of Woolwich itself dealt with?—It goes into the main metropolitan sewers and is carried down to Crossness.

6678. Is that true of the drainage of North Woolwich?—No; from North Woolwich it is carried direct into the river at North Woolwich, and the sewage of part of East Ham too.

6679. Is there a reservoir for the reception of that sewage?—Yes, at North Woolwich.

6680. Was that made at the expense of the Metropolitan Board?—They contributed something towards it, but it was done by the Woolwich Local Board, because the Metropolitan Board would not go to the expense of connecting North Woolwich with their main system.

6681. I think that reservoir is situated just above the North Woolwich pier, is it not?—Yes; it has nothing to do with the main drainage.

6682. But it pours its sewage into the river separately?—Yes.

6683. Does any other district in your neighbourhood contribute to the sewage that passes through that outfall?—East Ham.

6684. Is it your view that this outfall contributes somewhat to the pollution of the river?—To a small extent it does.

6685. Do you know the condition of the river Lea?—I have been up it sometimes in a boat. It is, I should think, rather worse than the Thames, if anything.

6686. Its waters flow into the Thames, in your district, I think?—Not in our district; above our district, at Blackwall.

6687. Is it your experience, having known the river a long time, that at Woolwich there is an increase of the filth on the banks of the river since the opening of the outfall?—A great increase, and the colour is darker; it is black now, it used to be brown. It used to be a natural mud, and now it is not; it is an artificial mud.

6688. You have for a long time given especial attention to this question of the pollution of the river, have you not?—I have read a great deal about it, but I am not a scientific witness.

6689. But you have made yourself as familiar as you could with all the reports on the matter?—Yes; being on local boards I have taken an interest in the subject.

6690. Have you, from your reading and from personal inspection, been able to come to any practical opinion with reference to this question?—Yes, I have formed an opinion.

6691. What is your opinion as to what ought to be done with the sewage of London so as to improve the present filthy condition of the river?

(*Chairman.*) We should be glad to postpone this part of the inquiry for the present. We have first to inquire whether the present system is not sufficient. If it is sufficient we should not trouble the witness.

6692. (*Mr. Balfour Browne.*) It will be more convenient, of course, to keep the two branches of the inquiry distinct. (*To the witness.*) It is suggested on the other side that the smells from the river are indistinguishable from those from the factories; is that so?—I can distinguish between the two.

6693. And there is no doubt about the river having a smell of its own?—In hot weather certainly. I was requested by my Board to represent the great accumulation of filth on the river bank since the sewage has existed there.

6694. (*Chairman.*) Of what part of the river are you speaking?—Of the different shores of the river from Woolwich and below Woolwich, between Wool-

*Mr. E. Hughes.*

12 Dec. 1882.

wich and Erith. You cannot land from a boat now in many places where you used to be able to land, but you now come against a mud bank, and if you got out you would be suffocated.

6695. Is there a very considerable accumulation of this mud (as we will call it by courtesy) near the Woolwich pier?—There is some, but the worst part, of course, is near Crossness.

6696. And you told the Commission in the earlier part of your evidence that the colour of the deposit had entirely changed since the opening of the outfalls?—Yes, it is as black as ink.

Cross-examined by Mr. MICHAEL.

6697. Within what period do you say that you have noticed this accumulation of mud?—It has been very gradual; it began as soon as the outfalls commenced, and it has gone on increasing ever since.

6698. Have you been down there yourself?—I have noticed it getting worse every year.

6699. Was there no mud in 1864?—Not of the same character. There was mud prior to the opening of the outfall; but it was mud, and this is filth.

6700. Do you say that this mud is black on the surface at the present time?—Certainly.

6701. You have noticed that yourself?—I have, indeed.

6702. For what period have you noticed that?—For quite 10 or 12 years, and more I should think.

6703. And the mud before that was of an entirely different colour?—It was of an entirely different colour; it was not so dark in colour, and it was a different kind of mud altogether.

6704. Then do you say that at the present time the mud deposited, of which you complain, is black on the surface?—I do.

6705. And for how far does that extend?—I have tried to land at Crossness, and I could not find any bottom by sticking the scull in.

6706. I am not asking you about Crossness; I am asking you about the appearance which you have seen on the surface at Woolwich?—I am not able to say. I have not tried to land at Woolwich except at the pier; but I did try to land at Crossness and could not.

6707. But I understood you to give evidence as to Woolwich, and I want to know what it is that you have observed at Woolwich itself; do you say that the mud on the surface at Woolwich has much increased?—It has increased, decidedly.

6708. At Woolwich itself?—I think so.

6709. On which shore?—On the south shore, in the bight. By "south" I mean between the dockyard and the arsenal.

6710. And you have yourself seen an increase of mud in that part?—Yes.

6711. And black mud on the surface?—I believe so.

6712. But you must know?—You are speaking generally of the whole distance. I am sure that there is black mud at the bottom of Warren Lane.

6713. Where is that?—That is the boundary of the arsenal.

6714. With respect to North Woolwich, where the sewer discharges itself, is there any increase of mud there?—Between the gasworks and the Northern outfall there is an increase of mud.

6715. Is there any sewer at the gasworks?—I do not know.

6716. Is there any discharge of refuse matter there?—Probably there is; it is more than likely.

6717. Of course I do not put to you that the smells are the same; there are a variety of unpleasant smells, we know, in the river; but as you belong to these various sanitary boards, I may ask you what is the general condition of the health of your district?—A very low condition; there is a lot of low fever in Plumstead; there have been 173 cases of fever in the last 12 months.

6718. What is the sanitary condition of Woolwich?—Fair.

6719. Is it not the fact that the proportion of what we call preventible diseases, or those which are attributable to causes of infection, is extremely low in the Woolwich district?—Yes; that is because they ventilate their sewers.

6720. You have told us that you are not a scientific man, and I only want the fact and not the reasons. The proportion of typhoid fever, diarrhœa, diphtheria, and all that class of diseases is extremely low at Woolwich, is it not?—Yes.

6721. Is it not a fact that the district close to the river is even lower in its per-centage of these diseases than other parts of Woolwich?—I do not know. I have no means of telling that, because I am not aware that it is divided. It is divided into the arsenal district and the dockyard district. It is divided north and south, not east and west.

6722. I suppose your medical officer has reported to you from time to time?—We have no medical officer.

6723. How is that?—I do not know.

6724. Is there any medical officer at Plumstead?—Yes.

6725. How far is Plumstead from the river, where these cases of low fever occur?—It is bounded by the river on the north to a much greater extent than Woolwich is.

6726. We have had a gentleman here who has told us that these cases of fever occur at a distance of even three or four miles from the river; have you localised these cases of low fever?—Yes. I think you can localise them within a mile and a half of the river.

6727. When you speak of low fever, do you speak of ague and malarious fever?—There is no ague now. It used to be a very famous place for ague, but since the railway has been constructed the ague has ceased. There is a railway cutting which ventilates the marsh.

6728. Do you say that you have had any reports from your medical officers that typhoid fever, diarrhœa, and diphtheria, or any of that class of disease, was occurring near the river at Plumstead?—On the side of the town nearest the river there is a great deal of it; but between it and the river there is a place called Plumstead Marshes. After you have passed the arsenal the town of Plumstead lies at the foot of the hill, and rises up the hill.

6729. How far is that from the river at the nearest point?—The nearest point would be at Griffin Manor Way, about three-quarters of a mile from the river.

6730. Therefore, any emanation from the river would have to pass over three-quarters of a mile before it came to Plumstead?—Yes, beyond the Arsenal.

6731. And you have had no return made to you as to cases of disease at Woolwich, occurring near to, or far from, the river?—Not as distinct from the general health of the town.

6732. And the general health, you have told me, is extremely good?—It is fair.

The witness withdrew.

Mr. WILLIAM COLLINGRIDGE, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb., recalled; cross-examined by Mr. BIDDER.

*Mr. W. Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

6733. You said in your former evidence that you had watched the outfalls on a certain occasion, and that the sewage was running out on what apparently was the flood. Is it not the fact that you had the outfalls watched for a very considerable time with the result that the sewage was always, on those occasions, discharged on the ebb?—No, that is distinctly not the fact.

6734. (*Chairman.*) There are two questions put to you, one of which is, Did you have the river watched for a considerable time?—No, I did not.

6735. (*Mr. Bidder.*) I accept your statement that you have had it watched on these particular occasions; but is it not the fact that you had the outfalls watched repeatedly, and for a considerable time, and have observed no discharge upon the flood?—No, it is not the case that I have had it watched repeatedly and for considerable periods.

6736. (*Chairman.*) You have had it watched upon other occasions besides those which you mentioned to us the other day?—The outfalls were watched upon one other occasion, and that, I think, was in 1880.

6737. (*Mr. Bidder.*) I shall come to that in the course of your reports I think. I will take you through the reports in their order, as I have, since the last meeting of the Commission, had an opportunity of reading them and seeing what is in them. I believe the first report that you made, or the first that we have been furnished with, is one for the half year ending 30th June 1880?—That is so.

6738. I am not going, of course, through that report, but I see that there are one or two matters referred to there. First you report, at page 12, upon the school ships. Now the school ships, as we all know, are permanently moored in the river, and all of them below the outfalls, are they not?—All, with one exception, the "Warspite."

6739. Where is the "Warspite"?—She is moored off Charlton.

6740. Of the others, one is off Purfleet, I think?—One is off Purfleet; that is the "Cornwall."

6741. Two, I think, are off Greenhithe?—At Greenhithe there are two vessels, the "Arethusa" and the "Chichester." The "Chichester" is not used as a training ship, but she was until about two years since, I think. There are other vessels below.

6742. I see you report that, "In two only of the "seven training ships, containing altogether between "2,000 and 3,000 young subjects, were any cases of "zymotic disease observed in the course of the half "year; and the sanitary condition of most of these "establishments remained very satisfactory during "this period." May I take it that the two cases you refer to are those which follow?—Those are the two cases.

6743. First you speak of a boy affected with scarlet fever on the "Shaftesbury"; it is not suggested, I think, that that had anything to do with the condition of the river?—No.

6744. And then on the next page you mention that on the "Arethusa," notwithstanding the very favourable sanitary condition of the ship, there were several isolated cases of typhoid fever?—Yes.

6745. It is the fact, is it not, that although the "Arethusa" and the "Chichester" lie almost side by side off Greenhithe, for some reason or other the "Arethusa," for a considerable time, appeared more liable to disease than the "Chichester"?—That is so.

6746. And you yourself came to the conclusion that there was something peculiar to the vessel, or to some of her arrangements, that caused the disease?—I did.

6747. Then you speak of a report of the Local Government Board on what was supposed to be enteric fever occurring on the "Cornwall." I want to ask you, in order to identify it, whether that is the attack which was the subject of the subsequent report which we have already had put before the Commission, in which it was stated by Dr. Power that it was traced ultimately to trichinosis?—No, this was an outbreak in 1875, on which an inquiry was commenced by Mr. Netten Radcliffe.

6748. But you say, "As this outbreak, and also a previous one in 1875"?—I beg your pardon, it is so.

6749. Then I am right that that is the trichinosis outbreak?—Yes.

6750. Then you refer to something that occurred in 1875, in the time of Mr. Leach. If you turn to the latter part of your report, I find what purport to be extracts from the monthly report of the medical officer for July 1880. I asked you just now whether you had not had the outfalls watched on other occasions, with the result that there was nothing irregular in the discharge. You have described the condition of the water as being unsatisfactory, and you say that it had slate-coloured patches in it, and that you have taken samples of water from the darker patches, which were simply sewage, more or less diluted. I suppose those are the same patches that have been mentioned by you and other witnesses in evidence here. Have you the analyses of those samples which showed them to be more or less diluted sewage?—No; I said last Tuesday that they were not analysed.

6751. Then is that a mere general statement, not intended as representing the result of analysis?—It is not the result of analysis.

6752. Then you say that the river was so bad, that had the hot weather continued the consequences might have been very serious; that the source of the pollution then became a matter for serious consideration; that some portion of it doubtless was poured into the river from the metropolitan outfalls; and that, if the sluices were open during flood, this quantity might be very considerable. Then you go on to say that, with a view to obtain definite and exact information upon this point, you communicated with the Commissioner of Police, and that through his courtesy you had been able to have the outfalls watched day and night. "Up to the present time, however, the reports have "been satisfactory, proving the discharge to be "effected only during the first part of the ebb"?—The question was whether a repeated watch for a long period had been kept at the outfalls; I say, distinctly, no.

6753. You told me just now that you had not had them watched previously?—I said on one other occasion, and this was the occasion to which I refer, when it says distinctly that watch was kept for more than a week.

6754. At any rate, on that other occasion, as you say in this report, the result was thoroughly satisfactory?—Certainly.

6755. Do you not think it would have been fairer to mention that?

(*Chairman.*) That is hardly the question.

6756. (*Mr. Bidder to the witness.*) You mention also that there are "a large number of small outlets "which empty themselves into the river between the "great outfalls and Teddington Lock"; and you add, that in spite of all legislation upon the subject an enormous quantity of fœcal matter is still allowed to run into the river, and convert what would otherwise be a tolerably clear stream into a foul sewer. May I take it as the result of your observation at that time that enormous quantities of fœcal matter were running into the river from sources other than the outfalls of the Metropolitan Board?—That sentence clearly refers to the enormous amount of fœcal matter discharged into the river from all outfalls, including the great outfalls and those others mentioned.

6757. I am not asking you what this sentence means; but I ask you whether, as a matter of fact, your observation at that time did not lead you to the conclusion that enormous quantities of fœcal matter were being discharged into the river from sources other than the outfalls of the Metropolitan Board?—Certainly the quantity was large.

6758. And you appended a list, I see, of foul outfalls to that?—Yes.

6759. Is it the fact, as shown on that list, that several places upon the river not only have important foul outfalls, but that they were increasing in number in 1880? Take, for instance, Brentford: "Brentford "is one of the chief offenders of the upper river. "Nearly the whole of the sewage of the district is "emptied into the Thames. In 1878 there were "only 15 foul outfalls; there are now no less than

*Mr. W. Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

12 Dec. 1882.

"25"?—That is so, certainly. It does not follow that 25 is an increase on 15. It merely follows that 25 were observed on that occasion, and only 15 on a former occasion, because many of those openings and drains, some small and some large, are only uncovered at certain states of the tide.

6760. You made that reservation with reference to Chelsea,—that there was an apparent increase, but you did not know whether it was real,—but not with regard to Brentford?—It would certainly apply to all.

6761. Then you say, "Fulham is the upper boun- "dary of the Metropolitan Main Drainage Scheme. "In spite of this, however, it has added two foul "outfalls since 1878"?—There it must be clear that they were added.

6762. You mention again at Whitechapel three additional foul outfalls; at Limehouse the removal of nine, and four additional; at Poplar a large increase of 20, although several closets have been removed; and in both Poplar and West Ham you say that the apparent large increase is due to the fact that upon the last occasion Bow Creek was not included in the district upon which, you say, you reported in June last. Have you that report upon the West Ham outfall?—I have not.

6763. Can you get it and produce it before the Commission?—Yes; it was a letter.

6764. You would have no difficulty in producing it?—No difficulty whatever. (*See Appendix B.S.*)

6765. Meanwhile, is it the fact that you have from the West Ham outfall a very considerable and very offensive discharge of sewage?—It is.

6766. Am I right in this: that the West Ham outfall discharges into the River Lea just at Blackwall?—Yes, at some little distance up the river; it is a little way up Bow Creek.

6767. Can you tell the Commission what proportion of the sewage discharges at that outfall?—No, I cannot.

6768. You also say that there is a very large outfall conveying sewage from a number of houses on the banks; is that also in the River Lea?—That is in Bow Creek.

6769. Does that outfall still exist?—Generally speaking, undoubtedly.

6770. Then the next thing is of some importance, as to a matter about which there has been some dispute here. You say that Woolwich has made no change; that it has only two outfalls, one of which is a large and very foul outfall at the Beckton Gasworks?—That refers to North Woolwich.

6771. Is it the fact that there is up to the present time a large and very foul outfall at the Beckton Gasworks?—I cannot say that it is so up to the present time.

6772. Was it so the last time you were there?—The last time I saw it was, I think, fully two months ago.

6773. Then according to all your observations it exists?—Yes, the outfall exists.

6774. And it is large and very foul?—It was not so on the last occasion, and I have heard no complaint of it in the last 18 months.

6775. Have you had very frequent complaints from people engaged in the coasting trade, whose vessels were lying there?—I think about two years ago I had a great many complaints.

6776. What was the nature of the offensive matter that came from that outfall?—There was a certain amount of sewage; I think it was storm-water, and there was also a certain amount of tarry matter with it, gas liquor; but I have had no complaints from Beckton for the last 18 months or two years.

6777. Then you go, I see, to the south side of the river, and beginning up at Richmond you state that Richmond still empties the greater part of its sewage into the river; that when last inspected there were 13 foul outfalls, and now there are 19. Does that condition of things still exist?—I cannot speak from memory; but there is a later report upon the same subject, which would show any change. Speaking from memory, I suppose it is so.

6778. Nothing has been done, so far as you know, to divert the Richmond sewage?—No, I think not.

6779. Then Barnes is the next place which you mention which had added several fresh outfalls, and which is now credited with 32; does that remain in the same condition?—I believe so.

6780. Then you mention Rotherhithe as having removed two outfalls, but having 21 still remaining?—Yes, but those are all very small indeed.

(*Chairman.*) The issue that we have to try is the state of the sewage at the present time. The question is whether there is not now a great deal of sewage pouring into the river; but whether it poured in in 1880 is not very material.

6781. (*Mr. Bidder.*) You will remember the mass of evidence that has been called to show what was the state of the river in 1880. I should be very happy if the Commission say, We will exclude all evidence as regards the condition of the river in 1880; but I do not think my learned friends would be satisfied. (*To the witness.*) Then I see you point out that from Greenwich to Gravesend there have been no changes, and that the number of outfalls is still very large. May I take it that that is true at the present time?—Yes.

6782. And you sum up by saying that there were no less than 384 foul outfalls in your district at that time. Are you able to give the Commission the figure, if that figure has been altered, at the present moment, or shall I come to it in a later report?—You will come to it in a later report.

6783. Is it the case also that a very considerable and important contribution to the sewage matter of the Thames is made by the floating population?—Undoubtedly, a large amount.

6784. What do you estimate that floating population at?—It has been estimated by Dr. Leach at from 15,000 to 20,000. I have no means of checking it, but I believe it is too large an estimate.

6785. Now I have one or two questions to ask you with reference to your next report, which has been put upon the notes, and that is the report which is dated the 5th of May. That, I take it, deals with the second half year of 1880?—Yes.

6786. In the paragraph on the "river" you repeat your former statement about the slate-coloured patches, and about the samples being simply sewage more or less diluted: may I take it that that also relates to the same samples and that there have been no analyses?—Yes.

6787. I find again in that report you state that the quantity of sewage poured into the river would be increased if the sluices at the outfalls were opened during the flow of the tide, and that you kept a watch on the stations for more than a week, day and night, but no definite proof could be obtained. That appears to be a second occasion on which you kept watch?—This, I believe, is the same report.

6788. The other was dated six months before. On page 30 of the notes there is a statement that you kept a watch on the outfall station for more than a week, day and night, and could get no definite proof of anything irregular being done?—This is the same report, word for word.

6789. The one that you had already printed in December?—Yes.

6790. That is the same occasion?—Exactly.

6791. I may take it, without reading the report, that you were of opinion at that time that the foul outfalls, and matters that I have already spoken to, were a very serious cause of fouling of the river?—I was of opinion that all the sewage discharged into the river was a very serious fouling of the river.

6792. With reference to what you mention on the next page, as to there being 30 tons of condemned fish, which were in an advanced stage of decomposition, which caused an intolerable stench, and so on, was that in craft moored on the river?—Yes, moored off Billingsgate.

6793. Was it your duty to go and inspect it?—Certainly if it was there.

6794. Have you any doubt that you did do so?—None whatever.

6795. You are quite sure that that was not the occasion on which you were unwell?—I am perfectly certain about it. This was in August.

6796. Now we come again to the reference to the school ships. I see you report that, with the exception of the "Arethusa" and the "Cornwall," the health of the school ships had been fairly good; and then you speak of one case of scarlatina and one of typhoid fever on the "Warspite"; you do not suggest, I presume, that that has any particular connexion with the river?—I think the next paragraph suggests that there is a possible connexion.

6797. You say, "The typhoid fever occurred at the "time when the state of the river was at its worst, "and though it is impossible to attribute it to this, "still, without doubt, this in itself was quite sufficient "to account for it." You did not consider yourself justified at the time in saying that the river was the cause?—Certainly not.

6798. I suppose in so large a community as you have in these training ships you could not expect entire immunity from occasional attacks of fever?—No.

6799. You speak of the renewal of typhoid on board the "Arethusa." Without reading long passages about it, may I take it that the result of your observation with regard to that was that in your judgment it was something which on that occasion also was specially attributable to the condition of the ship herself?—Yes.

6800. You point out that the "Chichester," lying close by her, was thoroughly healthy?—Yes.

6801. You mention an attack of typhoid on the "Cornwall," and several previous epidemics, and I see you there suggest that the "Cornwall" was affected by her position off Purfleet, and that the sewage had something to do with it, and that the germs of the typhoid were brought down from London by the sewers. Have you any evidence that there was, in fact, any epidemic of typhoid in London at that time?—I think there was a good deal of typhoid fever at that time, but I am not able to say so positively.

6802. You do not suggest in your report that there was any prevalence of typhoid in the metropolis?—There must always be a certain amount.

6803. I do not think there is anything further in that report which makes it necessary for me to ask you any question. Therefore I pass to the next report, which you presented on the 6th of October. By-the-bye, is it the fact that the ship used for small-pox patients was moved recently to the neighbourhood of the outfalls?—It has been moved down about a quarter of a mile down the river below the "Cornwall," but on the opposite shore.

6804. And that the health of the patients has been improved by the change?—I believe there are none on board at all, nor have there been since she was moved there.

6805. Are you sure of that?—I believe it is so.

6806. (*Chairman.*) Have the small-pox patients been moved on shore?—They were all moved before the vessel was taken down, and I am certain that there have been none on board since.

6807. (*Mr. Bidder.*) In the report to the 30th of June 1881, you report that the health of the training ships during the past six months had been exceptionally good, not one case of infectious disease having occurred on any of them, and you add that this is remarkable, as the number of boys on all those vessels averages about 750, and those all at a time of life at which are they most susceptible to the influence of zymotic disease?—That is so.

6808. May I take it, as the result of your observation, that, so far as the general health of the boys is concerned, they could not have been in a healthier position?—Certainly not, so far as the health of the boys is concerned, because they are completely isolated from the risk of infectious diseases. I merely speak so far as zymotic disease is concerned.

6809. And with the exception of these special outbreaks, which have been usually traced to special causes, the boys upon the training ships upon the river have enjoyed remarkably good health and immunity from disease?—During the last two years I think that is so.

6810. Your next report is a special report dated the 8th of December, and presented on the 15th of December. You go into certain questions of analysis of water, and it appears that some samples were taken and given by you to Professor Wanklyn to analyse, and you mention a discrepancy between the result obtained by yourself and the result obtained by Professor Wanklyn, which, I think, you have also explained in a note. May I take it that Professor Wanklyn's results are more in accordance with the usual method of estimating the impurities in water?—No.

6811. You have mentioned there how, beginning at Teddington, and taking samples, you traced the water gradually increasing in impurity as it received the sewage of riparian districts?—Yes.

6812. I infer that the result of your observations at that time was, that, coming down from Teddington, you found a distinct increase of impurity attributable to sewage poured in from the banks of the river on each side?—Partly, undoubtedly.

6813. Then you mention that the impurity became more marked at the metropolitan outfalls. It is asserted in the next paragraph that the worst specimen examined was one taken at Barking on the 23rd of November, when the tide was running down, and which was reported to contain about one-fifth of its volume of sewage. Was that specimen taken by yourself?—The sample was taken by myself.

6814. Was it taken in the line of the sewage?—It was taken just at the edge, between the line of sewage and the river water.

6815. How far was it from the outfall?—I should think about 300 or 400 yards from the outfall.

6816. Have you an analysis which shows it to be one-fifth sewage?—I have not; that is a quotation.

6817. From whom?—As I say, "which is reported to contain about one-fifth." If you refer to the end of the report it gives Professor Wanklyn's own remarks, and it is taken from that.

6818. Will you identify it with any of the analyses which are set out in the Appendix, and tell me which of them it is?—Yes; that will be sample No. 15.

6819. Are you quite certain as to the exact distance and position from the outfall at which you took that sample?—Yes: I say about 300 or 400 yards below the outfall.

6820. Then I see that the result of your observations at that time also showed that when you got as far as Tilbury the sewage had vanished and the river was pure?—Yes.

6821. You also express an opinion, judging, as you say, by the literature of the subject, that the condition of the Thames has much improved since the Metropolitan Board of Works have carried the sewage down to Barking and Crossness?—I think there is no question about it. I judge entirely from the literature. I had no previous knowledge of the Thames.

6822. (*Mr. Abernethy.*) To what part of the river do you refer?—I refer there simply to the upper part of the river.

6823. (*Mr. Bidder.*) You do not say so?—I do not say so. I was asked to what I referred.

6824. What do you mean by the "upper part"?—I mean that, judging from the literature of the subject, I am under the impression, and believe, that the condition of the river below is very much what the condition of the river was above before.

6825. Then there is nothing more, except that I see you have given in an Appendix the analyses of these samples; were they all taken by yourself?—Yes.

*Mr. W. Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

12 Dec. 1882.

6826. In the report for the half year ending the 31st of December 1881, on page 11, you mention a great nuisance in Limehouse Creek; is that special to Limehouse Creek?—It refers particularly to Limehouse Creek.

6827. You speak of a nuisance which was found to exist at that spot; did you trace that to the same source?—Yes; there was a great deal of vegetable matter floating on the surface of the water. That had collected at the edge of the creek, and for some reason or other, chiefly on account of the large number of barges blocking up the creek, it did not get away. There were, I think, two closets communicating with three houses at the head of the creek, and this caused a good deal of nuisance. Those closets were done away with, and the creek was cleaned out.

6828. The report of the 5th of October of this year is, of course, a report that has been produced since we have been before the Commission, and I think all I need notice there is that you have spoken, as the result of your observation, of the continued good health generally of the boys on board the training ships?—Yes.

6829. May I take it that you find also that the health of the crews of vessels frequenting the port is generally good?—I think the port certainly is a fairly healthy port. There are great complaints from crews coming up the river and passing the sewage outfalls; but, taking the whole of the port into consideration, I think it is certainly a fairly healthy port.

6830. With regard to these foul outfalls which you speak of in the passages I have referred to, do you find that where you have a foul outfall discharging on the banks of the river there you get a local nuisance?—Where you have an outfall discharging at some point below low-water mark, and where discharge goes on at low water, of course you have some amount of local nuisance.

6831. And, as a matter of observation, you have found that in a good many instances?—Yes, in a certain number of instances, undoubtedly.

6832. You gave a general description of the mud, but have you ever analyzed the mud?—No, I have not.

Re-examined by Mr. Lumley Smith.

6833. As I understand you, before you come to the outfalls at Barking and Crossness, there are between that point and Teddington outfalls which you call foul outfalls?—Yes.

6834. And to a certain extent they pollute the river?—Undoubtedly to a certain extent.

6835. A good many of those that you mention in your report are single waterclosets and small outfalls?—By far the greater proportion of the 369 are very small indeed; many of them refer to single closets.

6836. And it is not an outfall, necessarily in the sense of a sewer, that is referred to?—It is simply any opening or drain from which you get sewage pouring out at any time.

6837. There are, however, among them some outfalls which cause considerable pollution, are there not?—There are.

6838. Are there many of the large outfalls as distinguished from the small outfalls?—The large outfalls are very few in number. There is a large outfall at Richmond. There are lower a good many small outfalls, at Brentford, for example, but most of those have been done away with. Then at some few points on the river there are a number of small ones together.

6839. (*Chairman.*) How many large ones can you speak of?—There is one at Bow Creek, the West Ham outfall. There is one at North Woolwich, and one at Beckton; that is scarcely a large one, it is a large opening, but there is no large amount of sewage coming out of it. I think those are almost the only large outfalls. Of course there is the West Kent outfall; that is below the metropolitan outfalls.

6840. (*Mr. Bidder.*) Have you mentioned Barnes?—I do not know of any large outfall there.

6841. You have said in your report that it discharges all its sewage into the river?—Quite so, by a number of small outfalls.

6842. Could you give us the population which drains into the river through these outfalls?—In the case of the upper ones I think it would be almost impossible to give it.

6843. (*Chairman.*) Have you the information in your office?—No, I have not. At Richmond especially there are a very large number of cesspools.

(*Mr. Michael.*) We shall be able to give that information.

(*Mr. Lumley Smith.*) West Ham is in the jurisdiction of the Metropolitan Board of Works.

(*Mr. Michael.*) No, it is a local board, entirely irrespective of the Metropolitan Board of Works, though it adjoins it.

6844. (*Mr. Lumley Smith to the witness.*) Then there is the floating population?—Yes.

6845. Is the result that the water of the Thames is to a certain extent polluted before it meets the sewage which pours out from the Barking and Crossness outfalls?—Yes.

6846. The sewage that pours out from the Barking and Crossness outfalls is not diluted entirely by freshwater, but by a stream which is already to some extent polluted?—Yes, by sewage-polluted water.

6847. With regard to the training ships, two of them, I think, are at Charlton?—One is at Charlton.

6848. That is some little distance above the outfalls, is it not?—Yes; that is the "Warspite."

6849. The "Arethusa" and the "Chichester" are at Greenhithe, are they not?—Yes.

6850. That is a good way off, is it not?—Yes.

6851. Which is the one which is at Purfleet?—That is the "Cornwall."

6852. I see that in one of the reports from which my learned friend has been quoting with regard to the "Cornwall" you speak of the position of the "Cornwall" as being unfortunate, and you say: "It "seems that with this unfortunate history of repeated "outbreaks there must be something radically wrong, "and I am inclined to attribute much of the blame to "the position of the vessel. She lies off Purfleet in "a bight, and the stream during the ebb, after striking "the opposite point, sets directly into this bay. At "ebb the current carries down the great volume of "sewage from the metropolitan outfalls with it. This "can be seen occasionally as a dark line on the "water, while at all times evidences of sewage can be "found in the mud on the foreshore." You consider that the position of the "Cornwall" is unfortunate, having regard to the health of the boys?—I do. I think that the "Cornwall" is moored in a very unfortunate position with special regard to the outfalls of the metropolitan sewage. It is too near the outfalls, and it is at a point where the sewage is carried directly round the vessel.

6853. And you find in that vessel repeated outbreaks of illness?—Yes.

6854. Apart from the sewage, I understood you to say that the isolated condition of the boys on a training ship was favourable to health?—Undoubtedly, so far as infectious diseases are concerned.

6855. They run less risk of catching fever and other illnesses than they would on shore?—Certainly.

6856. That would be something countervailing any disadvantage arising from the sewage?—Yes.

6857. I do not know whether you have formed an opinion as to the effect of this sewage upon health?—It is impossible to see the state of the water, and to know that such a large amount of sewage is poured into it, without believing that the health of persons living on the water, or brought constantly on the shores of the river, must suffer from the effects. I think there can be no question about it.

Examined by the COMMISSION.

6858. (*Chairman.*) That is the inference that you would draw?—It is, certainly.

6859. But from your experience of the river as a medical man, is it, or is it not, a fact that you have found very little, if any, complaint of loss of health arising merely from the smell on the river from the sewage?—You get very many complaints; but the difficulty with regard to the river is that it is almost impossible to get statistics. You lose sight of people on the river directly anything occurs to them. The population of the river is constantly changing, and if a man is taken ill you lose sight of him altogether.

6860. From your experience, are you of opinion that the sewage in the river has been prejudicial to the health of the people on or near the river, or merely that it is uncomfortable to them?—I think, unquestionably, that it has a distinct influence upon health; it must have.

6861. But you infer that it must be so without being able to produce any particular instances?—I do not know that I can produce any particular evidence, except my own case.

6862. With respect to the amount of the sewage discharged from these 369 foul outfalls, has that sewage any appreciable effect upon the purity of the river above the outfalls?—It is an infinitesimal quantity compared with the quantity from the metropolitan outfalls. The majority of those 369 discharge an exceedingly small quantity. In the case of the few larger ones, of course it is possible to get the exact amount.

*Mr. W. Collingridge, M.A., M.D., M.R.C.S., S. Sc. Cert. Camb.*

12 Dec. 1882.

6863. (*Mr. Bidder.*) You cannot give the Commission the population that drains into these riparian drains, other than the metropolitan sewers. I suggest to you that it is 400,000 or 500,000 people?—I have no means of checking that.

(*Chairman.*) That there is such a population is likely enough; but whether it drains into the river is another question. That population could hardly drain through 369 insignificant outfalls.

(*Mr. Bidder.*) For instance, I may mention that the population draining through West Ham is over 100,000.

(*Chairman.*) But I expect you will find that that place is full of cesspools.

(*Mr. Balfour Browne.*) Dr. Collingridge himself pointed that out with regard to Richmond.

(*Chairman.*) I am speaking of Barking.

6864. (*Mr. Bidder to the witness.*) Do you suggest that cesspools exist in Richmond to any large extent?—Certainly. I know it as a fact.

The witness withdrew.

(*Mr. Bidder.*) It will be recollected that when Sir Joseph Bazalgette gave his preliminary evidence he was asked at questions 109 and 110 whether he could give the quantity of sewage discharged at the outfalls since the year 1878. It is on record up to 1878 and published. He said he could do it, but that it would take some time to get it out. We thought it right to provide every information we could for the Commission, and it has been now taken out, and I propose to hand in, so that it may go upon the notes, a statement of the discharge of the sewage from each of the outfalls for the years 1879, 1880, 1881, and the present year up to the 22nd of November last, in the case of Crossness, and up to the 24th in the case of Barking. Perhaps it may be convenient that I should add, in explanation of what may seem a spurious amount of fluctuation in the Table, that it is dependent to a certain extent upon the rainfall of the year, because a good deal of the rainfall gets into the sewers, and that is the reason why you find that there is no continuous growth.

*The following Table was handed in.*

5th December 1882.

DISCHARGE of SEWAGE from the BARKING and CROSSNESS OUTFALLS during the years 1879, 1880, 1881, and 1882, up to 22nd November for Crossness and 24th November for Barking.

| | | Gallons. |
|---|---|---|
| 1879: | Barking - - | 33,616,848,827 |
| | Crossness - - | 31,065,965,556 |
| | Together - | 64,682,814,383 |
| 1880: | Barking - - | 32,390,858,252 |
| | Crossness - - | 29,533,247,494 |
| | Together - | 61,924,105,746 |

Mr. JAMES MOORE MASON called in and examined by Mr. LUMLEY SMITH.

6865. You reside at East Greenwich, do you not?—Yes.

6866. I believe you are a member of the Greenwich District Board of Works?—That is so.

6867. And you are familiar with the drainage of Greenwich?—Yes.

6868. I see by the map that the main outfall sewer of the Board of Works passes from the Deptford pumping station through Greenwich?—That is so.

6869. And it passes along the Trafalgar and the Woolwich roads?—Yes.

6870. Is Greenwich drained into that sewer?—The whole of the Greenwich district is drained into it.

6871. That sewer has been in existence, I suppose, since 1864?—Yes, when the main drainage system was first constructed.

*Mr. J. M. Mason.*

6872. Was Greenwich then drained into it, or has it been joined since?—Greenwich was drained into it at the time.

6873. For some time did the system work well, as far as Greenwich was concerned?—So far as I know, it did; to the best of my belief, it did.

6874. For some years have you found it a matter for complaint?—Yes.

6875. At what seasons do you find matter for complaint?—Principally when there is a very heavy

*Mr. J. M. Mason.*

12 Dec. 1882.

rainfall the sewage increases in quantity. The large sewer is then incapable of holding the amount of sewage which comes into it.

6876. Does the sewage make its appearance in Greenwich?—The result is that it comes up into the lower basements of the houses in the neighbourhood, and in some instances it flows through the gullies or traps on the main road. I have seen it on one or two occasions; and also in the Greenwich Marshes I have known it to force up the manholes when they have been locked down.

(*Mr. Bidder.*) I must take the opinion of the Commission as to whether we are not now travelling entirely beyond the scope of this enquiry. The Commission is sitting to enquire into the system under which sewage is discharged into the Thames by the Metropolitan Board of Works, and whether any evil effects result therefrom. The matter which this witness is giving evidence about is the fact that, as he states, under certain conditions it does not discharge into the Thames, but comes into the streets. It may be a very serious and important complaint, but it is not one that we have to deal with here.

(*Chairman.*) He is only speaking of its getting into basements and through gullies, but perhaps eventually it gets into the Thames.

6877. (*Mr. Lumley Smith to the witness.*) What becomes of the sewage when it gets free from the sewers and makes its appearance in the houses?—I have known it run into the open ditches in Greenwich Marshes, and at low water to empty itself into the Thames, on those particular occasions especially when I spoke of the great volume of sewage running into the sewers and forcing up these manholes or man-traps, or whatever they are termed. I am not up in the technical matters.

6878. Then on those occasions it has got into the Thames at Greenwich?—Yes, at Blackwall Point most likely. There are several outfalls there, along that district.

6879. And that you say you have known at low water?—The open ditches discharge themselves at low water.

6880. Has that happened on more than one occasion?—Yes; I have known it on two or three occasions.

Cross-examined by Mr. Bidder.

6881. On two or three occasions in how many years; since the sewers were opened?—Since the sewers have been constructed, of course.

6882. You have known it on two or three occasions at Greenwich in all that time since 1864?—I have known it more particularly in the last 15 years. I have been a resident in Greenwich 15 years.

6883. How much sewage, on those occasions, got in that way into the river?—I cannot tell you. I am not prepared to say.

6884. Did you see any?—Yes.

6885. Did you see it discharged into the river?—I know for a fact that it discharged into the river.

6886. Where did you see it discharged into the river?—I know for a fact that it discharged itself into the ditches, and of necessity it went into the river.

6887. In any considerable quantity?—A considerable quantity. I could not tell you what quantity.

6888. Did you trace it into the ditches?—Yes; and I made a complaint to the Board of Works about it, because it interfered with my own business.

6889. Had it raised the level of the water in the ditches?—Yes, a great many feet.

6890. You have not many feet to come and go on in those marshes?—Yes, we have. I have seen the water at some times four feet higher than at other times.

6891. Was this an occasion of a very heavy rainfall?—Yes.

6892. How long ago was the last occasion when it happened?—I can only tell you from memory. To the best of my belief, it was certainly within the last three years.

6893. On one occasion when the rainfall was not only very heavy, but something almost unprecedented within so short a time?—The greater the rainfall, the greater the amount of sewage to discharge.

6894. That we know. But on this occasion was the amount of rainfall so enormous as to be the subject of considerable remark?—Yes.

6895. And of course all the ditches on the marsh lands were full of water?—Yes, they would be; but they empty themselves each tide.

6896. They were necessarily full until low water came, and then they got a chance of discharging themselves?—Yes.

6897. (*Chairman.*) The two or three occasions of which you speak were within what time?—Within the last four years, I should think, when that particular state of things occurred.

6898. (*Mr. Bidder.*) Is it the fact that the Metropolitan Board of Works are at the present time actually making a large additional sewer for the purpose of relieving that district, so that it will be impossible for such a thing to recur?—It is a fact that the Metropolitan Board of Works are making a new sewer in the Deptford district on the London side of the pumping station, to throw the water into the Thames.

6899. Will the effect of that sewer be to relieve the sewer through Greenwich?—I am quite willing to answer any question that I know about; but if I do not know it, I cannot answer.

6900. Does the course of that sewer run through Greenwich?—No, the one that they are constructing now runs through Deptford. Originally it came into the pumping station.

6901. Where does that sewer run from and to?—This new sewer that they are constructing now runs from the Lewisham district, and joins the old sewer at Deptford.

6902. (*Chairman.*) Has it joined it?—I am not quite sure whether it has at present; but it is intended to. It originally came into Deptford Creek; when there was a large overflow it ran into Deptford Creek.

6903. (*Mr. Bidder.*) Do you happen to know that the great mass of the water that came on the occasions you speak of, and increased the volume in the sewers, came from the Lewisham direction down the Ravensbourne?—No, it came from the pumping station at Deptford Creek, or the Ravensbourne on the Greenwich side.

6904. But the water did not come out of the pumping station; it must have come from somewhere else?—I am prepared to say that it did come from the pumping station.

6905. Are you aware that the object with which this sewer is being constructed is to relieve the sewers of that water which caused the overflow that you spoke of?—

6906. (*Chairman.*) Have the Metropolitan Board of Works told you that?—Yes.

(*Mr. Lumley Smith.*) I think the witness scarcely understood the question.

6907. (*Chairman to the witness.*) Mr. Bidder asked you whether the object of the Metropolitan Board of Works in making this sewer was to have a certain effect, and I asked you whether you knew anything about it?—It is made to relieve the Lewisham district.

6908. How do you know that?—It has been stated so on our Board.

6909. Who stated it?—The officers of the Board.

6910. (*Mr. Bidder.*) It is an official communication with the Metropolitan Board of Works. Being a member of the Board, do you not know that it is in consequence of your Board complaining to the Metropolitan Board of Works of these things that have happened that this sewer is being made?—Just so.

(*Chairman*). That confirms the story about there being this overflow.

Re-examined by Mr. Lumley Smith.

6911. Deptford is where the storm overflow is, is it not?—It is.

6912. You told us that a great deal of the water came from Deptford Creek?—It is a mistake if you understood me so. I did not intend to convey that impression. The pumping station is insufficient for taking away the whole of the sewage that comes into it; there are five or six sewers that run into the pumping station.

(*Chairman.*) If I am not mistaken, Sir Joseph Bazalgette himself mentioned something about this very matter, and if we have the high authority of Sir Joseph Bazalgette, what do we want with any such authority as this witness?

(*Mr. Lumley Smith.*) Merely to show that in cases of storms the system gets overpowered.

(*Witness.*) Quite so; that is just the point.

*Mr. J. M. Mason.*

12 Dec. 1882.

The witness withdrew.

Mr. George Robert Mason called in and examined by Mr. Balfour Browne.

6913. I believe you happen to be a brother of the last witness?—Yes.

6914. Where do you live?—Lower Road, Deptford.

6915. And I think you are a member of the Deptford and Greenwich District Board of Works?—I am.

6916. And you have taken some interest at the meetings of that Board with reference to the question of sewage in your district, have you not?—Yes, I have a little.

6917. What have you reason to complain of in the Deptford district with reference to overflow?—I have some houses in the parish of Deptford, near to the Thames, and the tenants complain very often there of the stench from the river, and it keeps continually getting worse.

6918. Have you any particular complaint to make with reference to the overflow of the sewers within the Deptford district?—Though I live at Deptford, my brother and I—not the last witness—represent the firm of G. and H. Mason, Market Gardeners, of East Greenwich, and on some occasions I have known the sewer that exists in Greenwich Marshes to overflow after a heavy rain, and a large quantity of sewage to be emitted. I recollect, on one occasion in particular, the force of water was so great that it blew the tops off the manholes.

6919. Where did the sewage get to after it burst out of the sewers?—It came into the roadway, and from there it ran into the open ditches.

6920. And from thence?—From thence it went into the Thames.

6921. Was that upon more than one occasion?—Yes.

6922. Do you know anything about the Deptford storm outfall?—I know where it is. I pass over Deptford Creek every day, and sometimes twice a day. I was a fortnight back at the railway wharf buying some clover, and my attention was then drawn by the man on the wharf, who knew me to be a member of the Board of Works, to an accumulation of garbage, I may say, that came from the sewer.

6923. Was that near the outfall?—Yes, within 200 yards, I should think.

6924. Was the accumulation large or small?—I should think that there would be quite a cart-load of floating sewage, as it were. It laid in a kind of dock where Mr. May, the proprietor of the railway wharf, unloads his barges, on the ways where the barges lie.

6925. Can you tell the Commission whether there has been any damage caused to the barges in Deptford Creek by reason of the sewage?—I am not quite clear upon that point, but I believe there has.

*Mr. G. R. Mason.*

Cross-examined by Mr. Bidder.

6926. Are you also a member of the Local Board?—Yes.

6927. On one or two occasions you say there were these overflows?—Yes.

6928. Is it not the fact that your Board complained to the Metropolitan Board of Works?—I believe they did, more than once.

6929. And in consequence of those complaints the relief sewers were ordered?—Not to my knowledge.

6930. You say that certain garbage was pointed out to you by a man on the wharf?—Yes.

6931. Do you know where it came from, of your own knowledge?—He drew my attention to it, and told me it came there. He is manager of the wharf.

6932. Is it the fact that there are foul outfalls in Deptford Creek?—I am not conversant with the whole of the Creek. There was a drain running through a yard into the Creek, but I believe that has been remedied. There is an outfall from the sewer in Church Street, Deptford.

6933. That is the storm outfall?—Yes, but sewage comes as well.

6934. Are there not other outfalls quite distinct from the outfall in Deptford Creek?—Not to my knowledge.

6935. Have you examined it?—No.

Re-examined by Mr. Balfour Browne.

6936. But I understand you to say that from that storm outfall sewage comes?—It must follow that, if the storm water comes through the main sewer, the sewage must come with it.

The witness withdrew.

Adjourned to to-morrow at half past 12 o'clock.

# THIRTEENTH DAY.

## Wednesday, 13th December 1882.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

COLONEL C. B. EWART, C.B., R.E.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

(*Mr. Lumley Smith.*) I am going now, with the permission of the Commission, to give some evidence about the rainfall; and to make that intelligible I would remind you of the evidence given by Sir Joseph Bazalgette on the first day of this inquiry. In the first day's evidence, at question 9, you will find that Sir Joseph Bazalgette stated, that in preparing the present system of sewers it was found from tables of rainfall that there were only from 14 to 21 days in the year on which the rainfall exceeded the rate of a quarter of an inch in 24 hours. The result is that on occasions of storms, when the sewers would carry off the storm water, the sewage goes direct into the Thames. We are informed that the rain that falls exceeds what I may call the prescribed rate on many more days than the number stated by Sir Joseph Bazalgette, so that the sewage would go direct into the Thames on many more days than was anticipated.

MR. GEORGE JAMES SYMONS, F.R.S., is called in, and examined by MR. LUMLEY SMITH.

*Mr. G. J. Symons, F.R.S.*

13 Dec. 1882.

6937. I believe you are a Fellow of the Royal Society?—I am.

6938. And you are, I think, a Past President of the Meteorological Society?—I am Past President, and I am now Secretary.

6939. You are the editor of a publication on British Rainfall, are you not?—Yes, I receive the returns from rather more than 2,000 stations throughout the kingdom.

6940. I think that for many years you have devoted your attention to the distribution of rain?—Almost exclusively from 1860 to the present time.

6941. I will take you first of all to the fall of rain in the metropolis. I believe you are informed of the evidence that has been given by Sir Joseph Bazalgette, as to the sewers being so constituted as to take the sewage and a quantity of rain equal to a quarter of an inch in the 24 hours?—Yes, or, as Sir Joseph Bazalgette put it, $\frac{1}{100}$th of an inch per hour.

6942. Have you prepared some tables, or are you able to tell us the result of your investigations as to the number of days on which rain exceeding that amount has fallen during the last two years?—I can go rather further than that. With the permission of the Commission I should like to offer a little information upon the point. Until a comparatively recent date rain gauges have been used which were only capable of giving the total fall during the 24 hours. With the exception of a gauge which exists at the Royal Observatory at Greenwich, there was not in the metropolitan district, or anywhere near to it, any means of determining the distribution of the rainfall over the 24 hours; that is to say, whether it all fell in two or three hours, or whether it was distributed over the 24 hours. Since about 1875 there have been gauges constructed which are self-recording, writing down the quantity minute by minute as it falls. Up to the present time I only know of four such gauges in the vicinity of the metropolis. There is the one at the Greenwich Observatory, to which I have already alluded, and which, being at a height of about 50 feet above the ground, collects less than the true quantity. It is a well known fact that rain gauges on roofs or elevated buildings catch too little. For that reason the Greenwich observations are not altogether available, and moreover, up to the present time they have not been published. There is another self-recording gauge kept by myself in the north of London, at Camden Square, which has been at work for about two years; but the records have been somewhat interrupted by the clock-adjustment not being perfect, and the observations have not been discussed. It could be done if it were desired. Another gauge is kept at Croydon by Mr. Baldwin Latham, and part of the results of that have already been published in one of my volumes. I think it might be as well if I were to put that in at once. I will place one copy before the Chairman (*handing in a book*). This is a communication by Mr. Latham published by me 18 months ago. Mr. Latham will, of course, subsequently be examined, and therefore you can receive it from him if you prefer it.

6943. (*Chairman.*) He will verify that if you will give us the result of your own observations?—I will come to that directly. I have now dealt with three of the gauges. The fourth one is at the Kew Observatory; that is under the Meteorological Office, which is a Government Department. The observations have been printed *in extenso*, and have been published, and are consequently accessible to any one. Those observations I have carefully discussed; but before taking out any of the values I thought carefully over what had been said as to the rate of a quarter of an inch per diem, and I rather gathered that it was possible that during certain hours of the 24, the amount of sewage going through the sewers was less than it was at others, and that possibly sometimes a greater amount than $\frac{1}{100}$th of an inch per hour might pass down the sewers. Consequently, I thought that instead of taking $\frac{1}{100}$th it would be fair to take perhaps $\frac{2}{100}$ths; that is to say, doubling the quantity suggested by Sir Joseph Bazalgette. Then there is another thing which is evident, namely, that in extremely dry weather, and under certain conditions, all the rain would not get into the sewers; and therefore that if you have $\frac{1}{100}$th of an inch falling, it does not follow that you have $\frac{1}{100}$th of an inch of rain in the sewers. For that reason I proposed further to limit it by assuming that only half the rain which fell got into the sewers. That involves a further doubling of the quantity, raising the minimum amount from $\frac{1}{100}$th of an inch first to $\frac{2}{100}$ths on the score of extra capacity in the sewers, and secondly, doubling it because of the possibility of all the rain not getting into the sewers. For that reason I took $\frac{4}{100}$ths of an inch per hour, and I carried out that investigation back for four years. The work is very heavy, and I have only four years done, and as the four years give very nearly the same results, it does not seem worth while to carry it much further. I start with the year 1880, which is the last year which has been published, 1881 and 1882 are not published. I have the tables *in extenso*, and I propose to hand them in. The tables contain the hourly rainfall at the Kew Observatory on days on which the rate of fall reached or exceeded one inch per diem; practically it is ·96 in., because ·04 in. multiplied by 24 gives ·96 in.; but it may be taken at one inch. Without going through the whole of the details, I may say that the abstract shows that the total number of days with falls of $\frac{4}{100}$ths of an inch per hour, or upwards, was in the year 1880, 83; in the year 1879, 95; in the year

1878, 82; and in the year 1877, 104. The average for those four years is, therefore, exactly 91. In looking through these figures I was struck with the fact that, instead of the ·01 in. per hour being a rarity, there were a great many instances of ten times that quantity, or ·1 in. per hour. I therefore took out the total number of days with falls of ·1 in. per hour or upwards, and those numbers are, for the year 1880, 41; for the year 1879, 37; for the year 1878, 38; and for the year 1877, 35; the average being 38. (*The following tables were handed in*).

ABSTRACT of the Records of the hourly fall of Rain at Kew Observatory, 1877–80.

| Years. | Total No. of Days with Falls of ·04 in. per hour or upwards. | Total No. of Days with Falls of ·10 in. per hour or upwards. |
|---|---|---|
| 1880 | 83 | 41 |
| 1879 | 95 | 37 |
| 1878 | 82 | 38 |
| 1877 | 104 | 35 |
| Average | 91 | 38 |

HOURLY RAINFALL at KEW OBSERVATORY on DAYS on which the RATE of FALL reached or exceeded (0·96 in.) one Inch per Diem.

6944. (*Mr. Lumley Smith.*) I do not know whether you are able to tell us the number of days in the year on which the rainfall in the whole of the 24 hours exceeded a quarter of an inch; have you checked that?—Not for this inquiry, but I remember looking into that point 15 years ago. The figures are printed, and I believe they are in my own volume of Rainfall for 1867. The value was, I think, 35 days of a quarter of an inch or upwards.*

6945. However, your tables which have been handed in show the hourly rainfall, so that it would be possible to calculate what the amount was in each 24 hours?—Yes.

6946. You have, in addition to that, prepared some tables, have you not, showing the amount of water that falls in the basin of the Thames?—Yes; of course I receive a very large number of returns regularly, but when I was informed that this inquiry was going on I was instructed to obtain accurate records of the rainfall over the whole of the Thames watershed. But I was further instructed that it was of more importance to obtain the information in greater detail respecting the lower tributaries of the Thames than respecting that portion which, combined, flows over Teddington weir. The consequence was, that I started what may be described as two separate investigations. I have handed round to the Commissioners some maps†, which I believe are before them, and on these maps will be seen the various water sheds. The principal ones are coloured, merely in order to make them a little more visible, the main river being left white all through. On these maps certain large numerals will be noticed; those numerals do not represent quantities of rain, or anything of that kind; they are merely reference numbers showing the position of the localities from whence I have obtained returns; and those returns I now propose to put in (*handing in some tables. See Appendices F. and G.*)

6947. Will you explain to the Commission what calculations those are, and what deductions you draw from them?—The fact is, that there are no calculations in them, for these tables simply represent in a convenient form the amount of rain measured at the respective places, of which the names are at the head of the columns, and of which the positions are shown by the numerals on the maps already handed in; that is to say, the top station marked Reigate, Woodhatch Lodge, No. 1 contains the observations made at Woodhatch Lodge, Reigate, in the month for which the sheet is, and the site of that gauge is shown upon the map by the figure 1, and the same remark applies to both tables. As to the deductions to be drawn from those tables, that is a question for engineers and not for myself.

6948. (*Chairman.*) Do these dots mean that there was no rain on those days?—Quite so. There is only one other point which I have to remark about, and that is this: that as a rough guide to the Commission as to the distribution of rain during the different months, I have had the values for two stations, for Oxford as representing the upper watershed of the Thames, and for my own station at Camden Square, as representing London, plotted on this diagram (*producing a diagram. See Appendix H.*) The heights of these various columns, as shown by the scale at the end, indicate the amount of rain. It is a scale exactly double the natural scale, and consequently shows at a glance the wet and dry periods during the months in question.

6949. (*Mr. Lumley Smith.*) Reverting to the earlier part of your evidence, a quarter of an inch is ·25 in.?—Certainly.

6950. Then dividing that by 24 it would not give actually the $\frac{1}{100}$th of an inch, but practically you have taken the $\frac{1}{100}$th of an inch per hour as being more convenient to work with than $\frac{1}{96}$th in.?—Yes, besides it is a question of rate, and not a question of total quantity. It is very rare that you get an equable rain throughout the 24 hours.

Cross-examined by Mr. Michael.

6951. What is the total annual rainfall in London?—About 24½ inches.

6952. Am I right in supposing you to tell the Commission that there are 90 days on which an average of a quarter of an inch falls?—I said that there was that number of days on which the fall in the hour was the quantity which I stated.

6953. It may be, therefore, that for one single quarter of an hour there was that quantity of rain falling, which, if it was spread over the 24 hours, would have amounted to ·25 in. or ·24 in.?—I did not say anything about quarter hours; I referred to hours. What I stated was this: that the total number of days with falls of $\frac{4}{100}$ths of an inch per hour, or upwards (it may have only lasted for one hour) was 90.

6954. Therefore, your giving us 90 days is no criterion of the quantity of rain which fell in those 90 days; it is merely as I understand you, that there did occur one single hour within the 24 hours in which the quantity which you take as your standard,

* British Rainfall 1867, page 28.

† *See* Evidence of Mr. Whitaker, Q. 6988, and *Appendix M.*

fell?—Quite so; that is to say, that during that one hour (or it may have been more) the rate exceeded $\frac{4}{100}$ths of an inch per hour.

6955. Have you taken out the number of days in the year in which ·24 in. or ·25 in. fell?—No; that question was asked me by the counsel, and I said that I did that many years ago, and I then found that it was about 35 days.

6956. Since that time has it been above or below the average?—The rainfall has been above the average the last few years.

6957. When you have taken that quarter of an inch, what do you wish us to understand as the result of your evidence; do you wish us to draw any conclusion that that quarter of an inch falling, or the division of $\frac{1}{96}$th of an inch falling, would come into the sewers at any appreciable time within the time of its falling as rain?—That is rather an engineering question than a meteorological one. I provide the actual meteorological facts; the interpretation of those facts is rather a question for engineers than for myself. At the same time, every one knows that if there is a violent rain, the rain rushes into the sewers, especially in these days of macadamized roads, asphalted pavements, &c.

6958. You are a scientific witness, and you are so thoroughly conversant with these matters that I need offer no apology for asking you these questions. You take the quarter of inch of rain as falling over a certain area; would you tell me how far that area extends?—I cannot tell, because this simply represents the fall at one place, that is to say, at Kew.

6959. It may have been so limited as to be an area of an acre, or a quarter of a mile, or a mile; you have no record of that at all?—No.

6960. But when we have to consider the question of the quantity of water not merely falling, but entering the sewers, ought we not to calculate the area over which that rain fell?—Yes; but speaking from my general knowledge of rainfall, I am quite sure that there is nothing exceptional in the frequency which is shown at Kew. It is true that very large rainfalls of two or three inches in an hour or couple of hours, are intensely local, but that does not apply to values such as are given here.

6961. May I ask, as a very careful student, month by month, and year by year, of your valuable records, whether it is not a fact, especially in London, that any heavy rainfall is, as you say, "intensely local"?—Generally.

6962. Is not an essential integer in calculating the quantity of water which would fall into the sewers, and so cause the storm overflows to act, and cause what my learned friend calls the sewage to enter into the Thames, the area over which that quantity of rain fell?—I am not an engineer, and I have not the remotest knowledge at the present time of how many storm overflows there are, whether there are two or whether there are 20.

6963. I am asking you a general and purely abstract scientific question, and I am sure you will answer me candidly.

(*Chairman.*) Recollect that the witness has told you that he is a meteorologist, and not an engineer.

(*Mr. Michael.*) I am not asking him an engineering question. I have a very profound respect for Mr. Symons, and I know that he is a very valuable witness, but he misapprehended the intention of my question. (*To the witness.*) I have nothing to do with the quantity of storm overflows; I merely put that in incidentally, so as not to take you at all unawares, and in order to explain to you the bent of my question; and I ask you again, whether before we can make your statistics of any value with respect to the quantity of water flowing into the sewers, we must not of necessity know the area over which the rain fell?—I should like you to define what you mean by "sewers," that is to say, whether I am to understand the sewers to apply to a piece of London, or to the main drains carrying the sewage down to Barking Creek.

6964. The whole of the system of sewers in London; but that has nothing to do with my question. Putting London out of the question, supposing that you are called, as you often are, as a scientific witness in these rooms to give evidence as to the capacity of pipes to carry off certain quantities of water, in order to determine whether a pipe will carry off the rainfall of a district, is it not essential to know over what area the rainfall has fallen, so as to be able to calculate the quantity which the pipes will carry off?—Certainly; but, as I have already stated, from my general knowledge as an observer, I am sure there is nothing in these sheets but what would occur in any part of London where you might happen to have put your gauge.

6965. At the same time?—Most probably at the same time. There may be a few instances here of heavy rains at Kew when there would not be heavy rain in London, and *vice versâ*.

6966. Would you kindly define what must be the quantity of rain before your own expression of "intensely local" applies?—I should say that a fall of upwards of an inch per hour is usually a local fall.

6967. How many such falls have occurred during the last five years, because they must be very rare?—That is hard to say. I have had two instances of $2\frac{3}{4}$ inches at my own place in five years. I do not suppose there is any other place in London that has had that luck, but I have happened to do so. I should think you might say that there have been perhaps eight or ten falls exceeding an inch in an hour. But I adhere to my original statement that certainly as regards this value of which we get the average of 90, I do not think that is disturbed to the extent of 10 per cent. by what can be called local falls.

6968. Supposing that there are 1,700 miles of sewers, and a velocity, I will say, of a mile per hour in the sewers, how long would your $\frac{1}{10}$th of an inch of rain take, if it had fallen over the whole of the area covered by these sewers of the metropolis, before it got to the outfall at Barking.

(*Chairman.*) That would require exceptional powers of calculation.

6969. (*Mr. Michael to the witness.*) Is it not obvious that if $\frac{1}{10}$th of an inch falls, say, at 6 o'clock in the morning of to-day, and is distributed over the whole of the system of sewers of the metropolis, it must take a very long period before the rain which has fallen at the extreme limit of the sewers will get to the other end?—I do not think so. Of course you are taking me off my own beat, as I said at the beginning, because I know nothing about the flow of sewage at all.

6970. Have you no observations at all on this pluviographical or hydrographical map which you have given us of the quantity of water that flows over Teddington Lock?—No, that is an engineering question. I have not the remotest idea of the quantity.

(*Mr. Lumley Smith.*) We shall be able to give that later.

6971. (*Mr. Michael to the witness.*) Nor can you tell us what influence an inch of rain, or $\frac{1}{10}$th of an inch, or $\frac{1}{96}$th of an inch, would have upon the river Thames?—Certainly not.

6972. Could you not give us any information with respect to the temperature during the period to which your observations refer?—I could get it probably as I could get any other scientific information which was required; but I have not investigated the point in any way whatever.

Examined by the COMMISSION.

6973. (*Colonel Ewart.*) Would you consider that, taking one day with another, the fall of rain registered at Kew Observatory would be a fair sample of the general fall over the metropolitan area?—I am quite sure that it would.

6974. (*Chairman.*) Then the result of your evi-

*Mr. G. J. Symons, F.R.S.*

13 Dec. 1882.

dence is that you think that for about 35 days in the year the rainfall would have exceeded a quarter of an inch in 24 hours?—I think it would have been ten times as great. Sir Joseph Bazalgette, I believe, puts it that a fall of a quarter of an inch per diem, or at the rate of the $\frac{1}{100}$th of an inch per hour (for it is only a question of rate) is a very extraordinary thing. In fact, it very seldom rains when it does not rain as much as the $\frac{1}{100}$th of an inch per hour.

6975. (*Mr. Abernethy.*) Sir Joseph Bazalgette stated that there were only from 14 to 21 days in the year on which the rainfall exceeded the rate of a quarter of an inch in 24 hours?—My answer to that is that it scarcely ever rains without exceeding that rate. If you go through these tables, which are detailed tables, there is no entry taken out which does not, during one hour of the day, exceed ·04 in., and the great bulk of these entries are much larger. I have underlined all the instances which exceeded $\frac{1}{10}$th of an inch per hour, ten times the quantity which he speaks of.

6976. (*Dr. De Chaumont.*) I do not think your last answer quite conveys what you intended to convey in saying that it seldom rains without raining as much as is stated by Sir Joseph Bazalgette?—It seldom rains at all without raining at a rate exceeding that which Sir Joseph Bazalgette looks upon as an exceptional limit. It is a question of rate as compared with the question of total quantity. Sir Joseph Bazalgette referred to a rate of a quarter of an inch per 24 hours; I say that you will find it scarcely ever rains at all unless it rains at a greater rate than that.

6977. Can you tell us what is the mean difference in any one day between the maximum and minimum over the metropolitan area?—It varies from nothing up to 400 times. I mentioned that there have been two instances of rainfall of $2\frac{3}{4}$ inches at my own house. On one of those occasions, towards Hampstead they had $4\frac{1}{4}$ inches in the 24 hours. On the other occasion the whole of the $2\frac{3}{4}$ inches fell in about an hour and three-quarters. It was about the heaviest rain I ever knew, and on that occasion the gauge at the New River Head registered something under half an inch, showing that the fall had fallen off from $2\frac{3}{4}$ inches to three-quarters of an inch or half an inch in three-quarters of a mile.

6978. That is an extreme case; but take a case where over the metropolitan area there was no greater rainfall than one inch at any one place; what would be the variation between that and the minimum?—I should say very probably from $\frac{8}{10}$ths in. to $1\frac{2}{10}$ths in.

6979. So that no station would give less than $\frac{8}{10}$ths of an inch?—I should think not. I should think the variation would not be more than 20 per cent.

6980. So that a rainfall of three-quarters of an inch to an inch would be pretty general over the metropolitan area?—It is usually so. I cannot go into all the details, but I recollect on one occasion I mapped a rainfall of about $1\frac{1}{10}$th in. which had fallen over the metropolis, and finding it was very equable over the metropolis, for curiosity's sake I prolonged it over the whole of the South of England, and I found a variation of only $\frac{1}{10}$th of an inch at all the stations up as far as the latitude of Bedford. The whole of the southern part of England had almost a precisely identical quantity; so much so, that I found who were good and who were bad observers by the irregularity in some of the amounts.

6981. (*Chairman.*) Would you draw any inference from the duration of the rain as to whether it was local or not?—Yes; as a rule these heavy rains are rains of very short duration.

6982. And therefore more local?—Quite so. It is the thunderstorm rains which are the local ones.

6983. (*Mr. Lumley Smith.*) I suppose if it was a short rain that only lasted for half an hour, or an hour, that would appear by your tables?—It would; because you have all the hourly details.

6984. (*Mr. Michael.*) But we have not the localities?—No, because there is only one; but, as I told you in the earlier part of my examination, I can have my own observations tabulated for the same period as are given here at Kew, and you can compare them with those at Kew. I do not think that there is anything else that is possible to be done besides that.

The witness withdrew.

Mr. William Whitaker, B.A., F.G.S., called in; examined by Mr. Balfour Browne.

*Mr. W. Whitaker, B.A., F.G.S.*

6985. You are a Fellow of the Geological Society of London, are you not?—I am.

6986. And you have been for 25 years on the Geological Survey of England?—Yes, for rather more than 25 years.

6987. In the course of your work in connection with the Geological Survey have you mapped the greater part of the Thames valley?—I mapped, I may say, by far the greater part of it myself.

6988. And I suppose this is the map that we have before us?—Yes. (*See Appendix M.*)

6989. In the course of making that map, I suppose you have acquired a very intimate knowledge of the geology of the whole of the Thames valley?—Yes; and not only of the part that I personally mapped myself, but I have had, as a rule, I may say, to see all, or nearly all, the other part mapped by various colleagues. I have practically seen all of it.

6990. I suppose in paying attention to the geology of the Thames Valley you have had to pay great attention to the question of water in the chalk?—Yes, it is a subsidiary subject to which I have given a good deal of attention.

6991. Have you made any special examination of parts of the valley of the Thames for the purpose of giving evidence before this Commission?—Yes; I have specially examined certain parts, as it was some time ago that my survey was made, in order to refresh my memory, and look at any special points that were involved.

6992. Can you tell the Commission whether or not wells in the valley of the Thames are commonly affected by the rise and fall of the tide?—Yes, it is a very common thing along the Thames valley, as along the margin of the sea and other water borders, that the wells should rise and fall with the tide to a greater or lesser extent, according to circumstances.

6993. Does the water in those wells become brackish in consequence of the infiltration of water from the river?—In some cases it does; not in all cases; but there are cases in which the water is not improved from that cause.

6994. For the purpose of this inquiry, I think you wish to make some remarks as to the geology of the valley of the Thames, first above London, and then below London?—Yes.

6995. First taking the valley of the Thames above London, are there any chances there of the infiltration of water through porous strata into the earth?—Above London, at least until you get to the neighbourhood of Windsor (which, of course, is beyond the limit of this inquiry), but certainly for a long way above the tidal part of the Thames, there is very little chance of such infiltration; indeed, the only chance of its occurring is through the permeable surface deposits off gravel and sand which overlie the London clay along the course of the river.

6996. Then, speaking generally, above London the river flows in impermeable strata?—Except the surface deposit. Underneath that there is an impermeable bed of clay of considerable thickness.

6997. (*Chairman.*) Can you give us any idea of the average thickness of that bed of clay?—It varies enormously, according to the position; but along the river it would reach probably to 400 feet at the most. When you get to Chertsey, I suppose there may be

about 400 feet of London clay. I cannot speak off-hand, it might be only 350 feet; but the gravel is thin; the gravel would rarely exceed 20 feet, but it is very irregular, it is generally less, very rarely more.

6998. (*Mr. Balfour Browne.*) The gravel which forms the bed of the river lies on the London clay, does it not?—Yes.

6999. Turning your attention to the river below London, is the same remark true of the bed of the river there?—No; below London a very different state of things sets in for the most part.

7000. What takes place there?—There is a slight rise of the beds, so that when you get below London the beds beneath the London clay rise up to, or nearly to, the surface; to the surface, I may say.

7001. Has the river so cut the London clay as to touch these beds below the London clay?—Yes, for some little distance below London; in fact, almost at the eastern edge of London the river begins to cut into these lower beds, and continues to do so for a great many miles, very nearly to the Nore; to below Thames Haven, in fact.

7002. And at Thames Haven I think the London clay comes down again and forms the bed of the river?—Yes, some little way below Thames Haven, before reaching Southend, that must be the case; the beds sink again.

7003. But between Thames Haven and the eastern edge of London, say Rotherhithe, are there permeable strata in the bed of the river?—Yes, and on the banks for the most part.

7004. Will you tell the Commission what those beds below the London clay are?—Those beds, we may say, are practically four in number. The first three are beds of Tertiary age; between the London clay and the chalk, beds more of the age of the London clay; a little older, but allied to it in age.

7005. Of what do they consist?—The first of those are what we may here call the Blackheath beds, beginning from the top in the order in which they rise from beneath the London clay.

7006. And that is the order in which you go down the river?—Yes. The Blackheath beds consist mainly of flint pebbles in a sandy matrix, and occasionally there are beds of sand as well.

7007. I suppose those beds of pebbles are permeable?—Perfectly, all through. They are sand and pebbles, and nothing else, in this particular district.

7008. What is the next in order?—The second in order to those is the set of beds known in this district as the Woolwich beds. They are a more varying set of beds. They consist of clays, of sands, and of pebbles.

7009. What about the permeability of those?—Of course the clayey part of them is not permeable, but the sands and the occasional pebble beds are permeable. They are very irregular in character; the clays are not always persistent, neither are the sands; they are an irregular set of beds, more clayey in one part and more sandy in another. In this particular district they are very largely sandy.

7010. (*Chairman.*) Where do they extend from?—The first set of beds (Blackheath Beds) occurs first in the neighbourhood of Greenwich. They are rather local; they extend to Erith, and then in patches eastward along the banks of the stream. The second set (Woolwich Beds) occurs between Deptford and Rotherhithe; they begin before the others, and they extend from there right down the river valley, except where they have been worn away and the chalk occurs.

7011. (*Mr. Balfour Browne.*) What is the third in your series?—The third is the mass of fine sands (except for a slightly clayey bed at the bottom; slightly clayey, I say, because it is more sandy than clayey), known as the Thanet sands.

7012. Are those permeable?—Yes, they are permeable throughout.

7013. And where do those beds occur?—Those beds occur first close to where the last-mentioned beds begin, a little above Deptford, and they extend afterwards right down the valley and far beyond it.

7014. What is the fourth set?—The fourth is the chalk, the lowest bed that we get in this part of the Thames valley.

*Mr. W. Whitaker, B.A., F.G.S.*

13 Dec. 1882.

7015. Where does that extend from and to?—It extends from Deptford right down the valley, being occasionally hidden, however, from just below Woolwich to near Erith, by some of the beds just described. In the neighbourhood of Woolwich, and from just above Erith to below East Tilbury, the bottom of the valley is wholly cut in chalk.

7016. Is the chalk a very permeable stratum?—Yes, as a rule it is, especially the part with which we have to deal here, that is to say, the upper chalk. We have nothing to do in this district with the lower, and sometimes less permeable, beds of the chalk; we have only the top 200 feet perhaps to do with, or not so much; 100 feet, I should think.

7017. You have described these permeable beds lying in the bed of the river; can you tell the Commission whether, at any part, the deposits of mud in the bed of the river would prevent infiltration of water into these permeable strata?—In some parts it is very probable that deposits of mud might have such an effect; but in a very large extent of its course, in the bottom part of the river itself, there is comparatively little mud, because we find that gravel, which is the same as that underlying the marshes, and occurring at the sides of the valley, is dredged up from the bottom of the river constantly; and more than that, there are places where anchors and such things touch the chalk itself, as near Gravesend.

7018. So that, where it does occur, its effect is simply local in protecting the permeable beds in the water?—Simply local.

7019. Is it your opinion that in the Thames below London there is plenty of opportunity for the infiltration of river water into the beds from which water may be drawn for supply?—Yes, the river valley there is so constructed, if I may use the word, or rather so cut out, that these mostly very permeable beds are open to the infiltration of water under proper conditions.

7020. If that water is charged with sewage, will the sewage also permeate into these permeable beds?—Naturally, a great part of any such water must be infected with any sewage that may be in it.

7021. Supposing that there are wells in the neighbourhood of the river, pumping water from those permeable beds, would that, in your opinion, facilitate the infiltration that you have been describing?—Certainly, if a large supply is pumped, it tends to lower the fresh water and to produce a cone of exhaustion which might result in a drawing in of the foul water.

7022. While the strata are thoroughly charged with water, that water would be, to some extent, a protection from the entrance of sewage?—Yes, while it is left in the natural state.

7023. But if that fresh water which is in the strata is pumped out, then it makes room for the sewage water to get into the strata?—Yes, it makes room for a certain amount of the bad water to get in.

7024. As a matter of fact, I think there were two large wells belonging to the Kent Waterworks at Charlton, were there not?—Yes, they had two pumping stations at Charlton on either side of the high road.

7025. Were those at any great distance from the river?—They are, roughly speaking, within a quarter or a third of a mile.

7026. And they are not very far from the southern outfall sewer of the Metropolitan Board of Works?—The southern outfall sewer goes very near them.

7027. Do you know as a matter of fact whether they have discontinued the taking of water from those wells?—Yes. I believe they have discontinued taking water from both of them now. They were used for some years. I cannot give the exact number of years, but they have been discontinued for some years now.

7028. Supposing the sewage to get into the river

*Mr. W. Whitaker, B.A., F.G.S.*

13 Dec. 1882.

and foul the water, would the effect of that sewage be found in the wells immediately, or would it take a long time, possibly, before it was found in the wells?—I should think that in many cases it would take a long time before the effect might be produced.

7029. Will you explain to the Commission why that is?—Because, of course, at first the amount of pollution would be comparatively small; it would not be until such sewage outfall had gone on for a long time that there would be so large an amount of foul matter in the river as to have an effect; and it would also take some time before the pumping would draw in such water.

7030. Therefore, of course, the more sewage there was in the river, and the more the pumping, the more you would expect the water to be affected by the sewage?—Certainly; as the throwing of the sewage into the river increases, and at the same time an increase of pumping takes place from new wells, or there is a larger drain on old ones, of course conditions are set up which are favourable to the drawing in of more water from the river.

Cross-examined by Mr. Bidder.

7031. The chalk basin under and around London is a great water-bearing stratum, is it not?—Yes, for the most part.

7032. It rises on both sides of London to hills of considerable altitude?—Yes, on the south nearly always, and on the north mostly.

7033. And the chalk under London, and under the River Thames, is charged with water which is under considerable pressure?—In most cases it is so, under natural conditions.

7034. And where it is bared to the river, the chalk would be a feeder of the river, and not the river of the chalk?—It would under natural conditions, or there might be a balance between them in some cases.

7035. So also, though possibly in a lesser degree, is it true of the upper beds, so far as they are water-yielding strata, that they are charged with water collected on the higher grounds?—Where they occur under the Thames, to a certain extent they would be, but the higher grounds are so much nearer that there would not be anything like the pressure there unless it were through the chalk.

7036. That is why I used the phrase "in a lesser "degree." Have you examined any wells?—Do you mean by gauging?

7037. I mean generally, in order to observe the fluctuations of wells with the tide?—No, I have not myself.

7038. Have you ever examined the phenomena yourself?—I have had records of them from many people, and information from the owners of wells.

7039. I suppose you know, as a geologist, that the fact of a well in the neighbourhood of a river, or of the sea, fluctuating in height in sympathy with the tide, by no means leads to the consequence that any of the water of the tide or of the river gets into the well?—Certainly; I have not said that it does.

7040. Have you any case to produce in which you have ever observed any well in the valley of the Thames which has exhibited any sign of being contaminated by sewage from the River Thames?—I have not actually observed the wells myself. I have not had an opportunity of doing so. I get records of hundreds of wells; I cannot see every well myself; I can only take the facts.

7041. Have you ever seen any instance yourself?—No, I have not. I have been at wells in which I have understood that there has been bad water, for instance, the trial boring at Crossness. I have been there while that was going on.

(*Chairman.*) We have the fact that he has not personally examined any of the wells.

Re-examined by Mr. Balfour Browne.

7042. I understand you to say that no doubt the chalk does at its outcrop get a considerable amount of rainfall into it?—Yes.

7043. In your examination-in-chief you spoke about a cone of exhaustion. When a well is sunk, does the well draw water from both sides of it, all round about it?—Generally speaking, it would, though it may be unequal on the various sides.

7044. So that if you sunk a well near the River Thames it would draw from the side on which the Thames was flowing as well as from the uplands where the water came from?—Certainly; it would have no more effect one way than another.

Examined by the Commission.

7045. (*Dr. De Chaumont.*) Have you any knowledge how far the tidal influence upon wells in the valley of the Thames is exercised?—No. I can hardly say off-hand. One hears occasionally of such an effect at a considerable distance, but I do not know that we have records at any very great distance. I fancy that is a question that will be answered by engineers better than by me. I cannot remember the records of the fluctuations of the water level.

7046. (*Dr. Stevenson.*) What distance were these disused wells from the outfall sewer?—I think they could not have been more than from a quarter to a third of a mile away. They were close by.

The witness withdrew.

(*Mr. Lumley Smith.*) I have one or two general witnesses whom I propose to call to-day, and I hope in January to bring what I may call the heavy engineering evidence before you.

Mr. Edgar Shand called in; examined by Mr. Lumley Smith.

*Mr. E. Shand.*

7047. I believe you are the manager of the London Steamboat Company?—Yes.

7048. Have you, all your life, been associated with the River Thames?—Yes, I was born on the banks of the Thames.

7049. Have you been conversant with the Thames all your life?—I have. I have resided in London all my life.

7050. Have you seen the sewage from the outfalls in the river?—Yes.

7051. Have you been able to trace it to see that it is sewage that comes from the outfalls?—Yes.

7052. Where have you seen it?—I have noticed it more particularly between Greenwich and Woolwich.

7053. Flowing in which direction?—I have seen it flowing both ways; I have noticed it flowing up the river as well as down.

7054. Your company is the company that carries all the passengers on the steamers up and down the river?—Yes, from Hampton Court to Ipswich.

7055. To what extent have you seen the sewage in the parts that you are speaking of, in isolated portions or in distinct tracks?—Distinctly in all parts of the

river, but more particularly between Greenwich and Woolwich, I have observed it. At Woolwich it was very bad.

7056. In the summer of 1881 did you see the river in a bad condition?—In 1881 it was the worst I have seen it. This present summer was not so very bad, but the year 1881 was very bad.

7057. What did you notice in 1881 which specially attracted your attention?—At those points, from Greenwich downwards, in fact, to the pumping station at Barking, I noticed the river very thick with a sort of glutinous matter, it seemed to be very thick indeed, and it was so bad that it used to cause bubbles. I noticed those bubbles, and I have seen them burst. It was in a very filthy condition.

7058. Was there any smell?—Yes, very bad indeed, the stench was something fearful, more particularly when the paddles of our boats moved from the pier.

7059. Have you had complaints about the river?—We have had continual complaints; in fact, I looked upon it as a very serious matter, on behalf of the company, at the time.

7060. From what class of persons did you get complaints?—From passengers, and from the captains and the men.

7061. Have you had any cases at all of actual illness caused to any of your crews?—No; not of actual illness, but we have had complaints of their feeling sick, and so on.

7062. Was that only in the hot months, that you have spoken of?—Yes, that was in the summer of 1881. I did not hear so much of it this year, although I have noticed it this year; but the river did not appear to be so bad.

7063. (*Chairman.*) You are speaking of very hot weather only?—Yes. In the winter time the water is very much better; but I fancy that that has a good deal to do with the land water that comes down.

7064. But, in point of fact, you have only observed that in very hot weather?—That is so.

Cross-examined by Mr. Bidder.

7065. How often does your duty take you between Woolwich and Greenwich?—In the summer time I am on the water every day.

7066. But between Greenwich and Woolwich?—Daily.

7067. When you say that you have seen the sewage between Greenwich and Woolwich, I want to get a little more definitely what you have observed; is it generally all over the river?—Generally all over the river.

7068. Of a glutinous consistency?—I have not noticed that glutinous nature this past summer as I did in the summer of 1881. In 1881 it was very thick indeed.

7069. Was it muddy to the sight?—No; there was evidence of soil from waterclosets, and all that sort of thing, floating about.

7070. You called it glutinous?—Yes.

7071. What you saw was general all over the whole river, and of course when the tide was going up it appeared to be going up, and when the tide was going down it appeared to be going down?—Yes, I observed it at all times of the tide.

7072. Did you trace it up above Greenwich?—No, I did not.

The witness withdrew.

Mr. Henry Jones called in; examined by Mr. Balfour Browne.

7073. Where do you live?—Woolwich.

7074. What are you?—A fisherman.

7075. And you have known the river a long time, I think?—Yes.

7076. I think you used to gain your living entirely by fishing at one time?—Yes.

7077. But now you have changed your occupation somewhat, have you not?—Yes; just now I have.

7078. What do you do now?—I get the fat off the river.

7079. Let me understand how you do this; have you a barge moored anywhere?—Yes, I have got a barge moored at Barking Creek.

7080. Is it in the creek itself?—Yes, inside the creek.

7081. How do you collect the fat?—I get it by a landing net, such as they have when they go fishing, when they catch the fish with a hook.

7082. Do you go out in a boat?—Yes.

7083. What do you do with the fat when you have collected it?—I take it on board and steam it in this barge that I have moored inside the creek.

7084. You go out in a boat, collect it into the boat, and then put it on board the barge and steam it?—Yes.

7085. I want to find out what parts of the river you get this fat in?—Sometimes at Blackwall, sometimes this side of Blackwall, and sometimes at Purfleet, according as the wind blows it.

7086. Do you ever go below Purfleet?—We could get it there, but there is not enough to pay us to go there.

7087. You stay at the fat part of the river?—Yes; there is a portion of it goes down below there a long way, but not enough to pay us.

7088. After you have steamed the fat, do you sell it?—Yes.

7089. I hope you make a good living out of it. I do not suppose you know what becomes of it afterwards, do you?—No.

Cross-examined by Mr. Bidder.

7090. Do you eat Dutch butter yourself?—No.

7091. Your barge is moored in Barking Creek?—Yes.

7092. And that is your headquarters?—Yes.

7093. At what time of the tide do you go?—Mostly upon the half flood, according as the wind is. It is the wind that has a good deal to do with our stuff; and we have to follow it about according as the wind blows.

7094. In the neighbourhood of the outfalls?—We have to go miles below, sometimes we have to go to Purfleet.

7095. You go to the eddies where the wind has blown the scum into a bay of the river, and there you collect it?—Yes, that is exactly it, and we get our living by watching the wind; where the wind blows it, we know where to find it.

7096. And that is what takes you sometimes up and sometimes down, according as a strong wind may blow it one way or the other?—Yes; sometimes it is all of a heap, and that suits us better.

7097. When the wind is not blowing, do you ever go actually to the outfall itself?—Yes, when there is no wind.

7098. Do you go close to the outfall?—Yes, we go there every tide.

7099. Do you enjoy pretty good health?—Yes.

7100. Do you ever work in Barking Creek?—Yes.

7101. You get a pretty good take there sometimes, do you not?—Very often we get a nice lot there; not far up the creek, about a quarter of a mile.

*Mr. H. Jones.*

13 Dec. 1882.

Re-examined by Mr. BALFOUR BROWNE.

7102. What part of Barking Creek do you get it in?—About a quarter of a mile from the mouth we get it.

7103. Can you tell where the fat comes from that you get in Barking Creek?—From the outfall. I am perfectly satisfied of that.

7104. How does it get in there?—The south-west wind blows it in; and the creek has a great draught to it, and it draws everything in it.

7105. Do you live on board the barge, or where?—I live at Woolwich.

7106. Has this fat that you get off the surface a disagreeable smell?—No, not at all.

The witness withdrew.

Captain HENRY WEBB called in; examined by Mr. LUMLEY SMITH.

*Capt. H. Webb.*

7107. I believe you are the captain of the "Cupid," which runs between Woolwich and London Bridge?—I am at present.

7108. And you have been employed on steamers plying up and down the river for 38 years?—Yes, for nearly 40 years.

7109. I believe you have a Trinity House Pilot certificate?—I have.

7110. And you know the river thoroughly, I believe?—I do.

7111. You remember the opening of the outfall, do you not?—Yes.

7112. At that time was the water between Westminster and Woolwich better or worse than it is now?—Worse.

7113. Since the outfalls have been opened, have you found any change in the water?—Yes, we get the stench further down now.

7114. And it is better up in the London district?—Very much better.

7115. And worse lower down?—Yes.

7116. What do you find to complain of in the water lower down now?—There is a very great stench when we get under weigh with our boats running down, when we are running two boats together. If we get to leeward at all, the boat to windward of us stirs the stuff up from the bed of the river, and it causes a great stench to the boat that is to leeward

7117. In what parts of the river do you find that?—From Barking to the lower part of Halfway Reach is the worst of it; but we have had it very bad from Blackwall to the "Rising Sun" point in the lower part of Long Reach.

7118. Have you seen the sewage above the outfalls?—I cannot say whether it is sewage, or what it is; I know the water is very black, and smells very bad.

7119. At what time of the year have you seen it?—In the summer season. I do not run down there in the winter.

7120. Have you had complaints from passengers?—Yes, frequently.

7121. What do they complain of?—Of the stench of the water. If a boat happens to be passing us at the time, there is hardly a passenger aboard but what is obliged to put his handkerchief up to his face to avoid the stench.

7122. That, I suppose, is in hot weather?—Yes; more especially in the year before last.

7123. Are you acquainted with the tides in the river?—Yes.

7124. First of all, with regard to the flood and the ebb, which is the stronger of the two?—The flood.

(*Mr. Bidder.*) You have exact experiments of Captain Burstal's, and surely it is not worth while going into this.

(*Mr. Lumley Smith.*) I have other evidence of exact experiments that have been made for the purpose of this inquiry.

(*Chairman.*) That will be more material.

Cross-examined by Mr. MICHAEL.

7125. Do you enjoy pretty good health?—Yes, very good. I am not often troubled with a doctor.

The witness withdrew.

Captain THOMAS HUNTINGFORD called in; examined by Mr. BALFOUR BROWNE.

*Capt. T. Huntingford.*

7126. I think you are the captain of the "Duke of Edinburgh," which is a steamboat in the service of the London Steamboat Company?—Yes.

7127. And you hold a pilot's and master's certificate from the Trinity House, do you not?—Yes.

7128. How long have you known the river?—All my lifetime; I was apprenticed to it.

7129. Can you tell the Commission how far from the outfalls the sewage is visible in the river?—I should think a couple of hundred yards.

7130. That is from the outfall into the body of the river?—Yes.

7131. Is the colour of the water at any other part of the river different from that?—No, not a wonderful deal; it is generally there where we catch the two different colours of the water.

7132. Is the water at any time in Crossness Reach, or Halfway Reach, as it is called, very clear?—It is never clear—pretty well half-water off.

7133. Is it always coloured?—Always.

7134. How do you account for that?—Through its being in an eddy, where it cannot get away.

7135. Is there not sufficient run of the tide through Halfway Reach to carry it through one way or the other?—No; only the first quarter's ebb tide that sets into Crossness; after that the eddy begins to form on account of the tide setting strongly from the Halfway House point down towards the Dagenham shore. A north-west wind would clear it away lower down the river.

7136. How does the flood set into the Crossness bight?—The first quarter's flood tide will set into Crossness; after that the eddy begins to form on account of the tide setting strongly from Jenningtree Point over to the Dagenham shore, leaving Crossness nearly three parts of the tide in an eddy.

7137. Is that after the young flood?—About the first hour-and-a-half flood.

7138. Is Bull's Point on the Dagenham shore?—Yes, only much higher up; Bull's Point is abreast of the Arsenal.

7139. What is the condition of the river, so far as the set of the tide is concerned, from Bull's Point to Woolwich Pier?—It is in a very bad condition. I notice the stench of the water more there than in any other part of the river. That is where I first fell in with it.

7140. (*Mr. Bidder.*) Where is Bull's Point?—Abreast of the Arsenal, on the north shore.

7141. (*Mr. Balfour Browne.*) At that place where you say you noticed it most, between Bull's Point and Woolwich Pier, is there an eddy?—Yes. I am speaking of North Woolwich Pier. The first quarter flood sets in there.

7142. And is that the cause of the stench of which you complain?—Quite so. After the first quarter-flood there is a down current that brings it back along the North Woolwich Gardens to Bull's Point, and there it will hold itself.

7143. Your evidence is that, owing to these sets of the tide, it does not get away?—It cannot.

Cross-examined by Mr. Bidder.

*Capt. T. Huntingford.*

13 Dec. 1882.

7144. Do you know that big drain at North Woolwich by the pier?—There is a drain pipe by the Telegraph Works.

7145. Near the Ferry Pier?—It is above the Ferry Pier.

7146. Have you noticed the stuff coming out of that?—No; only when they have a great deal of rain they are bound to ease it off the land.

7147. You are not aware that that drains a large number of houses?—No. I have been by it a good many times in a row-boat, but I never got any smell from it. I never saw anything come out unless there were heavy rains off the land.

7148. (*Chairman.*) What is the size of that drain at North Woolwich?—It is an iron pipe about four or five feet in diameter,* by Henley's Telegraph Works.

7149. (*Mr. Abernethy.*) Have you ever measured it?—I have not.

7150. (*Chairman.*) You could almost get into it?—Yes, I could get into it nicely. It lifts up with a large trap; but I never saw anything come out of it.

(*Mr. Bidder.*) I am not sure that you know the right one. We will get evidence as to this from somebody else.

Re-examined by Mr. Balfour Browne.

7151. At any rate you never got any smell from that?—No, never.

7152. (*Mr. Bidder.*) North Woolwich Pier is where you always find a smell?—Yes, in going down; if we gave a stir with the engine, that would throw up the scent from the water.

7153. Close by the Woolwich Pier?—Yes, alongside the pier.

Examined by the Commission.

7154. (*Chairman.*) Is there a pipe coming out into the river?—It comes out into the shore down to low-water mark.

7155. And you have seen stuff coming out of it?—I do not know that I have ever seen much come out of it. There may be a little water running out of it, but that is all.

7156. (*Dr. de Chaumont.*) You said that you traced the sewage from the outfall for 200 yards; do you mean across the river or up and down the river?—I mean across the river, with a strong south-west wind.

7157. How far up or down have you traced it?—I have traced it nearly a quarter of a mile up the river, up to Halfway House Point, above the sewers.

7158. (*Chairman.*) Then, when you said 200 yards, you meant across the river?—Across.

7159. (*Dr. de Chaumont.*) Have you traced it down the river also?—We can trace it down to Jenningtree Point; after that it all gets coloured alike very thick as low down as Greenhithe.

7160. (*Chairman.*) You never noticed it below Jenningtree Point?—Never to hurt. There is no smell.

7161. You notice it down to Jenningtree Point and up to Halfway House Point?—Yes, Halfway Reach is two miles in length. Halfway House Point is about a quarter of a mile above Crossness.

7162. Then you never notice it up as far as North Woolwich?—No; the water all seems to get discoloured alike when you get up there; but in Halfway Reach you see two colours like that table, one black and the other a lighter colour.

7163. The two things are in separate streams from Jenningtree Point up to Halfway House Point?—Yes.

7164. And then you say they meet, and you cannot distinguish them?—You cannot up at North Woolwich Pier, because they get into a truer run of the tide. This is in the eddy.

7165. When they do meet, have you noticed the state of the water from that point?—It is very thick.

7166. Up to where?—The river is all over alike now, pretty well.

7167. Up to where?—I would say as far as Greenwich, if the tide is running strong. It is according to the run of the tides. In spring tides it will be thicker than in neap tides.

The witness withdrew.

Mr. Edwin Martin called in; examined by Mr. Lumley Smith.

*Mr. E. Martin.*

7168. Are you the pier master at South Woolwich?—Yes.

7169. How many years have you been there?—Eighteen.

7170. Do you remember the opening of the outfalls at Barking and Crossness?—Yes.

7171. That would be, I suppose, about the time of your going there?—After that some considerable time. They have not been opened 18 years yet.

7172. When you first went to Woolwich were you pier master?—No, pierman.

7173. What was the water like then in the neighbourhood of the pier?—Very different from what it is now.

7174. Is it better or worse now?—Much better.

7175. Was it clearer or not?—It was much clearer. You could catch anything there then, flounders and shrimps.

7176. What is it like now?—It is different at times. When they let the stuff out of the sewers on the flood it is very black.

7177. Do you find that a blackness comes into the water then?—Yes; and there are little round balls of fat that drive by. That is the way we find out when they are letting it out on the flood.

7178. You find balls of fat come driving by the pier?—Yes.

7179. Do I correctly understand you to say that the water is blacker then?—Yes, much blacker.

7180. Do you find the balls of fat come by on the flood frequently?—After heavy rains or snow, or anything like that, when the sewers are heavily charged, they let this stuff out.

7181. Have you noticed at all the wind, so as to see whether these balls of fat are brought up by the tide or blown up by the wind against the tide?—If we have the wind on our shore, they will come on our side, and if it blows off our shore, they will go on the other side.

7182. Do they come up with the flood?—Not as a general rule, but sometimes after heavy rain or after low water you will see them as soon as the flood makes.

7183. Are you much troubled with mud at the pier?—At times, and sometimes it shifts.

7184. Is that stirred up by the tugs?—We have sometimes two or three of them at a time, and then they stir it up, and it is a sort of blue-black colour, and the stench is something horrible then; it is simply awful.

7185. Are you familiar with ordinary Thames mud?—Yes.

7186. Is it at all like that?—No, it is not at all like that; it is of a blueish black.

7187. Have you ever experienced any ill effects from it?—I could not say that I have. Twice this year I have been away for three days, but I could not say that that was the effect of this.

* Subsequently altered by witness to *two* feet in diameter.

Cross-examined by Mr. BIDDER.

*Mr. E. Martin.*
13 Dec. 1882.

7188. When did you last see the balls of fat off Woolwich Pier?—I saw them a hundred times this summer. I could not give any date. I was never "taxed" with any date.

7189. When was the last time that you saw them?—I could not say the date. I might say I saw them three or four times last month.

7190. How long have you been stationed there?—Eighteen years.

7191. Where were you before that?—Under Government; in the Ordnance.

7192. At Woolwich?—No, at sea.

7193. Then you must have gone to Woolwich about the year 1864?—I was born in Woolwich.

7194. I did not ask you where you were born, but you must have gone to Woolwich in 1864?—Yes, if that is 18 years ago. It will be 18 years, come the 28th of next month.

7195. It was in January 1865 when you first went to Woolwich?—Yes, on the 28th of January.

7196. Previously to which you had been at sea in one of Her Majesty's ships?—Yes.

The witness withdrew.

Adjourned to Tuesday, the 9th of January, at half-past twelve o'clock.

---

# FOURTEENTH DAY.

## Tuesday, 9th January 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, MEM. INST. C.E.
COLONEL C. B. EWART, C.B., R.E.
FRANCOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

9 Jan. 1883.

*Mr. Lumley Smith*, on behalf of the Corporation of the City of London, expressing his great regret that the scientific witnesses whom he had hoped to be able to call to-day, had found it impossible fully to complete their extensive observations, and the necessary deductions from them, prayed the indulgence of the Commission, and begged a fortnight's adjournment. At the same time he handed in sundry diagrams, with explanatory memoranda, of float experiments in the Thames.

*Mr. Bidder* urged that at all events the chemical evidence might be proceeded with, submitting that that must be to a large extent matter of fact, and independent of the engineering observations.

*Mr. Lumley Smith* stated that the labours of the chemists were so largely conjoint with those of the engineers and other scientific observers, that he was unable to proceed with the chemical evidence separately at the present moment.

*Mr. Bidder* was heard to protest against any delay which could possibly be avoided.

After a short discussion

*The Chairman* intimated that the Commission had decided that the next meeting should be fixed for this day fortnight, the 23rd instant, by which time the representatives of the Corporation should at any cost or trouble to themselves be ready to proceed; but that if by any chance they felt at the end of a week from to-day that it was impossible for them to be prepared by the 23rd, they must give notice and apply for a short extension of time; otherwise, failing such notice, the Commission would proceed peremptorily on the 23rd instant.

Adjourned to Tuesday the 23rd of January at half-past 12 o'clock.

---

# FIFTEENTH DAY.

## Tuesday, 23rd January 1883.

PRESENT:

THE RIGHT HONOURABLE LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOS. STEVENSON, ESQ., M.D.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

23 Jan. 1883.

*The Chairman*, in reference to a paragraph which had appeared in the newspapers purporting to describe the proceedings at the last meeting of the Commission, intimated that it must be clearly understood that all who were admitted before the Commission were present on sufferance only, and must conform to the rules laid down by the Commissioners, which prohibited any report or reputed report of their proceedings to the public press.

In anticipation of evidence, a "Report on the Observations made in the River Thames," by Mr. Baldwin Latham, M. Inst. C.E., was handed in. (*See Appendix R.*)

Mr. Baldwin Latham, M. Inst. C.E., F.G.S., F.M.S., examined.

7197. (*Mr. Webster.*) You are a civil engineer, practising at Westminster?—I am.

7198. Have you devoted your attention for a great many years to works connected with sewage and drainage, and to tidal outfalls?—I have.

7199. Were you, some months ago, requested by the City solicitor to investigate the discharge of the sewage into the Thames?—I was.

7200. About how long ago was that?—I think it was last June.

7201. I think Mr. Mansergh, Mr. More, and Mr. Birch have, from time to time, assisted you?—Mr. Mansergh and Mr. More were associated with me as engineers, and Mr. Birch was engaged in looking after the float experiments.

7202. Will you just tell us what steps you took, in the first instance, to ascertain the horizontal range of oscillation of the tides near the point of the northern outfall?—A series of floats of the description of the one which has been exhibited to-day were put into the Thames.

7203. And their motion was watched?—And their motion was watched night and day. There were two men engaged in a small boat by day and two men in a boat by night watching each float, and the men were generally superintended by Mr. Birch and his staff from the steam-tug "Toby."

7204. What are the dimensions of the floats?—The floats are 12 feet 6 inches in length and 11½ inches in diameter.

7205. And what cross section are they; are they circular?—They are octagonal, the object being to offer, as nearly as possible, the same surface to the water in every direction if they revolved. They were immersed about 12 feet on the average, sometimes more and sometimes less.

7206. That is to say, they would stand upright in the water?—They would stand upright in the water; if they were down in the lower part of the river they would be a little higher out of the water.

7207. (*Chairman.*) On account of the proportion of salt water?—Yes.

7208. (*Mr. Webster.*) The floats stood vertically in the river you say, and I want to know, taking the average, how much would be out of the water?—There would be from 6 inches to a foot on the average out of the water; as a rule, they would be immersed 12 feet.

7209. Would the maximum be 6 inches out of the water?—The minimum would be 6 inches.

7210. And the maximum what?—Perhaps a little less than a foot; it is very difficult to say precisely, because the movement of the surface of the water prevents your ascertaining exactly.

7211. With regard to the rise and fall of the tide, I suppose you took observations by tide gauges?—We have made use of such existing recording gauges as were upon the Thames, and we have put up a number of others, especially upon that part of the river (the lower part) where there were no gauges, and where it was more important to carry on the observations than in the higher part of the river.

7212. What do you take to be, for the purpose of your evidence, the total drainage area of the River Thames?—The total drainage area of the River Thames has been ascertained by the report of the Rivers Pollution Commission on the Thames, March 1866, to be 5,162 square miles.

7213. Have the Thames and its tributaries been gauged in any places?—Yes.

7214. In how many different places?—The Thames, and the whole of the tributaries which could be gauged, have been gauged, because it was of very great importance to ascertain what was the volume of water coming into the river at all points.

7215. (*Chairman.*) Taking the 5,162 square miles which you mentioned, to what point would they include?—Down to Southend—really to the mouth of the Thames itself.

7216. (*Mr. Webster.*) That is to say, going from Southend up to and including the water that comes in at Teddington?—Mr. Symons on the last occasion put in a plan which showed the drainage area of the Thames.

7217. (*Chairman.*) That means, I suppose, including its very source?—Yes, including its very source.

7218. And down to the mouth?—Yes.

7219. Inasmuch as we know that from its source to Sheerness the distance must be about 120 miles?—The river itself is 201 miles in length.

7220. But an air line from its source to Sheerness would be how much?—That I have not measured, but 201 miles is the length of the channel.

7221. The average breadth of the drainage area could not be above 50 miles?

7222. (*Sir John Coode.*) Speaking broadly, it is 50 miles?—No doubt.

7223. (*Mr. Webster.*) Of that 5,162 square miles, I think, 500 are due to the drainage area of the River Lea?—About 500 are due to the drainage area of the River Lea.

7224. You have given the drainage area to a point much below the outfall, I think you mentioned Southend?—Yes.

7225. For the purpose of your subsequent deductions, is the quantity of water in the river below the outfall a matter of importance?—Yes, of very great importance.

7226. Has the water flowing from that 5,162 square miles been gauged, with the exception of 284 square miles?—Yes. In the Report which has been put in you will see the number of the tributaries which have been gauged, but in some of these cases they were gauged at more than one point; there are 50 points at which we have carried on gauging operations.

7227. Will you tell me what steps have been taken to ascertain the quantity of water flowing from the 284 square miles which you could not gauge?—The quantity of water flowing from that 284 square miles has been arrived at by taking a similar area which has been gauged, below Teddington Lock, and calculating the number of cubic feet every day which has been found to flow from the ungauged area, to represent the exact area, and the result is given in the Table of Gaugings. That 284 square miles has been divided into two portions, one above the northern outfall and the other below it. I might say that the 284 square miles that were not gauged represent one-eighteenth part of the whole drainage area.

7228. Have you also taken the quantity which is taken for water supply purposes and afterwards returned to the Thames, after having been used?—Yes, we have taken the quantity from Colonel Bolton's monthly tables, and averaged it out to the daily quantity in the same way as the other gaugings have been taken.

(*Chairman.*) All this is in Mr. Latham's Report, is it not?

(*Mr. Webster.*) It is as far as I have gone.

(*Chairman.*) Because we have already looked carefully over this report.

(*Mr. Webster.*) That report, I hope, will be taken as having been put in—we could not, of course, take it as being read.

(*Chairman.*) Mr. Latham will, no doubt, say that report is accurate, unless he is inclined to correct or qualify it in any way, therefore that is his evidence to a certain extent.

(*Mr. Bidder.*) As far as we are concerned, that seems a desirable way of dealing with it, subject to one thing, and that is, that my learned friend at the proper time will call the witnesses who took these float observations. I have a very good reason for asking that that may be done.

(*Chairman.*) You do not agree that the observations themselves are accurate?

(*Mr. Bidder.*) I have the best reasons for believing

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.S.*

23 Jan. 1883.

that there are serious mistakes in the observations themselves.

(*Chairman.*) But still you may take it that Mr. Latham in his evidence in chief says, "This is my report, and you may take it as right."

(*Mr. Bidder.*) Of course he will not say that the observations themselves are correct, but that the calculations are correct as far as he is concerned.

(*Mr. Webster.*) It is essential that this report should be upon the proceedings.

(*Chairman.*) Certainly. It must appear upon our proceedings; there is no doubt about that.

(*Mr. Bidder.*) All I desire that my learned friend and your Lordship and the Commissioners should clearly understand in the present state of the proceedings is, that I shall challenge the correctness of many of the observations themselves.

7229. (*Chairman to the witness.*) Many of the statistics in this report are not, I presume, the result of your own actual inspection?—Of my own inspection they are; nothing has been done which has not been under my inspection and supervision.

7230. But you could not undertake to say that there is nothing here which is not within your own knowledge?—No.

7231. (*Mr. Webster.*) A number of the observations upon the floats were supplied to you by the people who actually watched the floats?—Yes.

7232. You have not constantly watched the floats yourself?—No, I did not of course watch the floats night and day.

7233. (*Chairman.*) You could not say, for example, that upon the morning tide of the 15th of October the float was 19·30 miles above the outfall?—No, I could not say that.

7234. (*Mr. Webster.*) Upon many occasions you saw the observation taken?—Yes.

7235. (*Sir John Coode.*) They were taken under your direction and supervision?—They were.

7236. (*Mr. Webster.*) But you relied upon other persons for the detailed figures which appeared upon your report and your diagrams?—Yes.

(*Mr. Webster.*) With regard to what my learned friend, Mr. Bidder, has said, subject to the approval of the Commission, the City will be prepared to call any witnesses he may ask for.

(*Chairman.*) Yes, if the Board tell you that they want any of those witnesses called, you must call them.

(*Mr. Bidder.*) What I mean is this, that I have a very grave reason for thinking that many of these observations (I do not suppose they were taken when Mr. Baldwin Latham was present) are inaccurate, and that very likely in the night the float has not been continuously at work. You will understand that it makes considerable difference in the progress of a float whether it has been anchored half the night or not, and therefore having good reason to believe that that has been the case in many cases;—

(*Mr. Webster.*) I intimated that I was ready to call anybody my learned friend required, subject to the discretion of the Commission.

(*Mr. Bidder.*) It is hardly for me to indicate the witnesses who should be called.

(*Mr. Webster.*) But you can say with regard to which float you would like to have those who made the observations examined.

(*Witness.*) I would like to call the attention of the Commission to the fact, that upon the afternoon tides the range is greater than it is upon the morning tides, showing that the float could not have been anchored.

(*Mr. Bidder.*) My learned friend is not going to rely upon my giving notice of a particular person to be called.

(*Mr. Webster.*) Certainly not, I am not going to be so unreasonable. I will give any class of evidence you require.

(*Chairman.*) Mr. Bidder may say, if he thinks fit, call A.B., or call the man who was doing this, that, or the other, or he may say, call all your men who furnished the materials from which Mr. Latham made his observations, and you will do it.

(*Mr. Webster.*) Certainly; we should not be here to produce this evidence before your Lordship if we could not do that.

(*Mr. Bidder.*) I ought to go a step further in fairness to my learned friend, and tell him that I shall at the proper time adduce in evidence simultaneous observations which are quite inconsistent with these, and therefore of course both cannot be right. I have told my learned friend that in advance, as I did not wish him to be taken by surprise.

7237. (*Mr. Webster to the witness.*) There are one or two data which I must get for the purpose of founding the equation upon. The position of the outfalls we know, will you tell us one or two distances which are necessary for your subsequent evidence. From the northern outfall to Crossness is about a mile and a half, is it not?—From the northern outfall to Crossness the distance is about a mile and a half.

7238. From the northern outfall to Erith pier is five miles?—That is correct.

7239. From the northern outfall to the Town pier, Gravesend, the distance is $14\frac{3}{4}$ miles?—Yes.

7240. And from the northern outfall to Cliffe Creek the distance is $18\frac{3}{4}$ miles?—Yes.

7241. Has a cross section of the river been taken at any point?—Yes, Mr. Mansergh and Mr. More have very carefully surveyed the whole of the river with the view to arrive at the capacity of the river from the area of the cross sections.

7242. And have you used those sections?—I have used them for the purpose of certain calculations.

7243. Will you tell me shortly what are the two actions which take place in order to get the sewage out to sea, from, we will say, the northern outfall, what happens to it, after it is turned out into the water?—After the sewage is turned out from the outfall it would flow down with the tide to a certain point and be brought back again by the next tide to a certain other point, up the river; and that process would go on, backwards and forwards, taking a longer time than one lunation, until fresh upland water coming into the river displaces the matter and gradually drives it out of the river.

7244. As far as the tide is concerned the sewage poured in at one outfall, taking the northern outfall for instance, would oscillate backwards and forwards?—Yes.

7245. That would be the action of the upland water, little in dry times, and heavy in flood times, to drive it further down the river?—Yes.

7246. What other process goes on which has a tendency to take the sewage out of the water?—The mixing, which has a very powerful influence, much more so than the actual displacement.

7247. Will you tell the Commission what you mean by the mixing action?—Mixing with sea water takes place when the water flows down the river; if you put a float, we will say, in the water, and let it float down the river, you will find by taking samples of the water, all along its course down the river, that the water becomes more and more salt as it passes down the river.

7248. Assuming a volume of sewage to be poured out on the top of high water, and that it would come into tidal water, partly salt and partly fresh, there being no sewage there before, as it goes down it comes into a wider area; the area of the cross section of the river increases in size?—Yes.

7249. Therefore, there would be a larger volume of water into which it would go?—Yes.

7250. Then when it is returned it is more diluted than if it had been in a parallel channel all the time of a small size?—Yes.

7251. This goes on contemporaneously, and is what you call the mixing action?—Yes.

7252. Is there also a mixing action due to the flowing in of fresh water at the top?—Yes, it takes place both ways. If there were no mixing action, all the water from the range of one tide to the mouth of

the river would be fresh water, but as it is, we found upon the 14th September, at high water, an amount of sea salt in the water at Chiswick, showing that it could only have been brought up to that point by the mixing action.

7253. I do not want to anticipate the detail. I will get that afterwards. You have examined as carefully as you could, to find out the effect of the oscillation or floating backwards and forwards of the dirty water, and also of its being mixed with other water?—Yes, I have.

7254. Have you put down the result of what you believe to be true observations in the shape of a diagram?—These diagrams before the Commission, show the various floats up to No. 7. (*See Appendices S. and T.*)

7255. Turning to the first page of the diagram, will you just show the Commission what was the operation of No. 1 float. I think you began upon the 14th of September and had to commence again?—The experiments were intended to begin at spring tides upon the 14th of September, but, owing to the men being new to the work and a fog coming on that night, the experiment broke down, and it was not until the 17th of September that the experiments were fairly started.

7256. You started upon the 17th of September at high water, at what place?—The float was put in the centre of the river at high water, opposite the northern outfall.

7257. How far did it float down?—It was put in at 25 minutes past 4 p.m. on the ebb tide; it descended as far as Denton Wharf, 15·84 miles below the point at which it was put in.

7258. Was the tide neap or spring?—The tides were then taking off; the tide had been high spring upon the 14th.

7259. How much was it after the high spring?—Three days.

7260. The course of that float is shown according to its tidal range, for the period of seven days, until it has reached a point opposite Higham Bridge, just below Holt; is that correct?—Yes.

7261. It appears to have gone higher up than the outfall between the 28th and the 29th of September?—Yes.

7262. I think the highest point it reached was just to touch Woolwich Station, was it not?—Upon the 29th.

7263. For how long was the float watched?—Upon the 29th of September the float had reached a point in Woolwich Reach, 2·08 miles above the northern outfall.

7264. Is there any special cause upon that day with regard to that float going up as high as that?—It will be seen that it was a spring tide, so that the range is greater and the wind was slightly up the river.

7265. Is the effect of the spring tide that the water flows up the river at a greater rate of rapidity than a neap tide?—Yes.

7266. It is not merely that a greater volume of water comes in, but it flows up at a greater rate of rapidity?—It must naturally do so if a greater quantity comes in.

7267. It has a larger quantity to get up in the same time, and therefore it must come up more rapidly, and therefore you will expect upon a spring tide to find a greater operation upon the float?—Yes.

7268. I think we will just go through them; upon the 13th of October that float was lost?—Whenever there is any hitch in the management of the float, it is shown by a black dot upon the diagram.

7269. I notice that upon the 17th of October the float got up still higher again?—Upon the 17th of October.

7270. Mr. Bidder suggests that it was lost altogether, will you show where it was found again?—You will see in the report what exactly happened upon that day. "Upon the 13th October, at high water, on the "morning tide, the float was in Halfway Reach, "1·76 miles below the northern outfall sewer, and "about two hours after the return of the float down "the river, a fog came on and the float was lost. At "noon the same day, it was again started in a position "with reference to No. 4 float, which had been con-"tinuously working during the period."

7271. That is to say, you put the float in when it was found again at noon the same day, the same distance from No. 4 float as it had been when it was lost?—That is so.

7272. How long did this float go on?—It went on continuously till the end of the observations, until the 24th of October.

7273. Then it was stopped by the gale?—The weather became very unsettled about that period.

7274. Will you tell me what general deduction you draw from that float?—It is given at page 12 of the report, that in the 45 days this float was in the river it only progressed 2·20 miles down the river; but if we take two complete lunations, ending upon the 16th of October, the float had descended two miles. In the 26 days, in which there was no break whatever in the experiments, that is, between the 17th of September and the 13th of October, the float had only progressed down the river 1·76 miles below the northern outfall.

7275. What do you mean by progressing down?—From the point where it was put in down to the point where it was found.

7276. From the point where it was at the beginning to the point where it was at the end?—Yes. At the same state of the tide.

7277. I believe No. 2 float, though it was lost, was found again, and there does not seem to have been much wrong with it during the fog; that was in continuously from the 17th of September to the 19th of October?—That is so. I may mention that with regard to that, as a condition of doubt occurred, it is shown by a dotted line on the diagram instead of by a full line.

7278. It is clear, by the dotted lines, that nothing happened to it, because it appears to have gone on in the same way as before?—Yes, that is so.

7279. (*Chairman.*) Of course this float would ground every now and then, unless your men in the boat prevented it, would it not?—All these float observations were done under written instructions from myself, and one of these instructions was that the men were not to interfere with the float unless it was likely to go aground, and then they were to pull it straight out into the stream again.

7280. When your float was lost in the fog very likely it did ground?—Where there has been any doubt about it that will be settled by contrast with previous experiments, but I do not think I have any evidence that it did ground.

7281. (*Mr. Webster.*) Just look at it with regard to these two tides; at the last tide, when it was observed upon the 9th of October, it was then just a little more than seven miles below the northern outfall?—That is so.

7282. Now it was next observed at high water the following tide, and it was then observed to be about $3\frac{3}{4}$ miles above the northern outfall?—The next tide that was so; it was only lost during the time that is shown by the dotted lines.

7283. It was observed to be at low water that same tide a little lower down, viz., $8\frac{3}{4}$ miles just above West Furlong Reach?—That is correct.

7284. Would that temporary loss of three hours, assuming it to be otherwise right, disturb the effect of the float experiment?—No, it is quite clear, looking at both the tops and bottoms of the ranges, that it was an accurate observation.

7285. Assuming that it was right at the end, and right at the beginning, do you think that three hours loss would have affected the experiment?—No.

7286. Even assuming it had been aground?—Even assuming it had been aground.

7287. (*Chairman.*) But the diagram shows it could not have been aground?—That is so; but assuming that it had been aground it had got in its right position again at the top of the next tide.

*Mr. B. Latham, M. Inst., C.E., F.G.S., F.M.S.*

23 Jan. 1883.

(*Mr. Webster.*) The dotted line is put in hypothetically, meaning that we do not know where that float was during that three hours; if it did get aground where the thick line ends, it must have floated off about the corresponding point of the flood, because we find it reaches the place it was expected to reach, having regard to the previous observations.

(*Chairman.*) That would, suppose it was out of sight, influx and reflux, but I understand the witness to say it was never out of sight more than three hours.

(*Mr. Webster.*) But the float is never out of sight in both the legs of the diagram. I submit that if the general float experiments are correct this particular error will not disturb the result.

7288. (*To the witness.*) You do not find, do you, any disturbing fluctuation in the diagram following that particular period of loss?—I do not; but even in this case the float was seen; it was reported as having been seen by a passing boat, and therefore we had knowledge with regard to the position of it at about low water.

7289. Will you tell us what the deduction from that No. 2 experiment is?—During the 31 days of observation the float advanced 1·3 miles down the river. That is taking one high water period as compared with another, because this No. 2 float was put in at half tide.

7290. At the end where was it? On the 18th of October, with regard to the beginning, was it 1·3 miles higher up the river?—It was 1·3 miles down the river at the high water periods, or 6·75 miles up the river at the half tide.

7291. At the corresponding half tide, when it ceased, where was it with regard to its position when it was put in; was it 1·3 miles higher up?—No; down the river. Then the report concludes by saying, "At the end of the two periods of lunation, ending "on the 16th of October, the float had ascended "1·33 miles up the river.

7292. What do you mean by a "lunation"?—Fourteen days.

7293. At the half tide, upon the 18th October, the corresponding tide, was it 1·3 miles above the point at which it was put in?—It had advanced 1·3 miles down the river at the corresponding period, that is to say, the next high water after it has gone down the river and up, because it is put in at half tide; and by comparing the period of high water with the high water at the end of the diagram, you will find it is 1·3 miles lower than at the commencement.

7294. But, at all events, at that half tide, it was 1·3 miles higher up?—I do not think that it was half tide when it was lost there.

(*Sir John Coode.*) I rather think you are speaking of a semi-lunation, while Mr. Webster is speaking of a full lunation.

(*Mr. Webster.*) Quite so. I ask you to deal first with a complete experiment.

(*Sir John Coode.*) I think the answer has been given with regard to a semi-lunation.

(*Witness.*) Taking it from the high water here to the other high water (*pointing to the diagram*), that is 1·30 lower down the river at the top of the tides.

7295. (*Chairman.*) At the end of the two periods of lunation, ending upon the 16th of October, the float had ascended the river by 1·33 miles, that is, it was a mile higher up the river than when it had started?—That is so; that is shown by comparing the two black lines.

7296. (*Mr. Webster.*) Will you tell us now what deduction you drew from float No. 3?—In 43 days it had made a progress from low water to low water of 13·80 miles down the river.

7297. At what time of the tide was that put in?—It was put in at low water.

7298. I may take it that you have put your deduction from these various experiments at the conclusion of the details of each experiment in your report?—I have.

7299. And you say those are correct?—I do.

7300. The first three floats are all put in on spring tides?—They were all put in when the tides were taking off after spring tides.

7301. Now, will you take No. 4 float?—No. 4 float was put in on high water at neap tide; No. 5 on half tide; and No. 6 on low water.

7302. Have you put the effect of your deductions also upon the diagrams?—The diagrams show everything with regard to the movements of the floats.

7303. Will you look at the last diagram of all in your book?—That refers to experiments which were made with regard to the mixing action; perhaps I ought to have explained the diagram which has been put in to show the influences which have been at work.

7304. With regard to the last diagram but one, does that show the phases of the moon?—Yes.

7305. And the direction of the wind?—Yes; these shaded columns represent the velocity of the wind at Greenwich, and the figures show the number of miles run (*pointing to the diagram*). The circles show the direction of the wind blowing from the periphery to the centre. The centre is supposed to be the head of the arrow; it is divided according to the two halves of the day, two circles for each day. The upper figure shows the quantity of water flowing every day in cubic feet per minute over Teddington Weir.

7306. This diagram shows wind force and direction, amount and condition of the tide, spring or neap, and the volume of water coming over Teddington Weir?—It does, and the phase of the moon.

7307. It also shows to the eye the amount of travel as well as distance in miles?—It shows the apparent vertical range of the tides by the figures at the bottom taken from the tidal record at Erith.

7308. What have you assumed in your subsequent calculations for turning the cubic feet into gallons?—If you multiply the number of cubic feet per minute by 9,000, that is to say, multiply it by nine, and add three cyphers, it gives the number of gallons in 24 hours.

7309. But what actual multiplier have you assumed for turning your cubic feet into gallons?—6¼.

7310. There were some simultaneous experiments also made which you call numbers 9 and 10, which are explained at pages 31 and 36 of the Report?—Yes, that is so. We should have made many more only the weather proved so rough. We tried to find whether there was any difference in the velocity of the tide in the various parts of the river.

(*After a short discussion*):

7311. I think you told the Commission a few minutes ago that you had also made some experiments for the purpose of testing the mixing operation?—Yes.

7312. Was that to ascertain whether the water was salt or fresh?—Those experiments were made with a view to applying practically the results that we had arrived at theoretically from the amount of chlorine that was found at various points.

7312*a*. That is to say, you tested various samples for chlorine, and from the result you could tell what the quality of the water was?—Yes.

(*Chairman.*) It would almost seem as though the effect of your observation was, that although owing to the mixing some water which went down might as it were be left, and other which had not gone down might be brought up, yet that taken as a whole no water had been discharged from the river during the 24 hours.

(*Mr. Webster.*) That is not quite so.

7313. (*Chairman.*) But your log went up higher than it went down?—Yes, but that is only the range of the tide during this time, but there was a current of upland water coming down, driving down everything before it.

(*After a short discussion*):

7314. (*Chairman.*) The log, if I understand, floated down and floated up, and its floating up, which must have been attributable to the action of the water, was

greater than its floating down ; was not that so ?—In some of the experiments it was, but not always.

(*Mr. Webster.*) In the first experiment it had gone down 1·7 miles, there are some in which it has gone down, and some in which it has gone up, but I do not think any deduction can be drawn to the effect that no water would have gone out.

7315. (*Chairman.*) You have told us of an entire lunation, that is to say, the moon beginning at one period of its age and going on till it reached the same period of age in the next; on that occasion the progression was up the river a trifle. I want to know whether I have rightly appreciated that?—That is, that the No. 2 float had gone up the river in the period in which it had been put in.

(*Mr. Webster.*) Your Lordship will be jumping to an erroneous conclusion if you take that view at the present moment. If I had gone through all the experiments in detail, you would have found many instances in which the float had progressed, for instance, 3·25 miles down the river ; and all I say is, that you cannot draw the abstract conclusion your Lordship does that the float necessarily worked upwards.

(*Chairman.*) I want to know if the witness will tell me how it could be, unless it were influenced by the wind or got stranded, that it would go up, which to my mind involves more water going up than going down.

(*Witness.*) At certain phases of the tide, when more water is coming into the river, that is, all the time that the tides are making,—the tendency is always for things to go higher up.

7316. That is because there is more water comes into the river than floats out ?—And at other periods when the tides are taking off, the tendency is for more water to flow out of the river, but this may be modified by the wind and the quantity of upland water coming down the river.

7317. But it could not be modified in this case by the quantity of water coming down the river, because the float went up, and if it is modified by the wind, it shows that the observation is to a certain extent fallacious.

(*Sir John Coode.*) When you speak of water going down the river, I take it that you refer only to the quantity of water flowing over Teddington Weir, and from the different tributaries of the Thames ?—Yes, that is so.

7318. (*Mr. Webster.*) May I put this question, as following upon his Lordship's. If you take one experiment and compare it with another, you sometimes find that it has gone up the river and sometimes you find it has gone down ?—Yes.

7319. Have you found, in the course of your investigation in this matter, that not unfrequently solid matter which sinks down to the bottom is found higher up the river than the point at which it was put in ?—There is no doubt that, owing to the superior influence of the flood tide, matters of a certain specific gravity can be picked up and carried to a certain point and there dropped, and the ebb tide will not carry them down again.

7320. (*Sir John Coode.*) Have you found it so ?—Yes.

7321. (*Chairman.*) I wished to know if I had rightly apprehended the witness's answer, and if so, what would be the explanation of the particular experiment. (*To the Witness.*) Suppose there had been no water over Teddington Lock at all, if it were an *impasse*, the log would simply float up and down except as it was affected by the wind, would not that be so ?—There seems to be a little misunderstanding with regard to this, because the ebb tides are much longer in their apparent flow than the flood tides, and if you take the relative velocity of each, you will find the velocity of the ebb is very much smaller than that of the flood. I find that the velocity of the flood tide is 192·2 feet per minute, while at the ebb tide it is 167·6 feet per minute.

7322. (*Chairman.*) The tide alongside of us at Westminster runs up for perhaps 5½ hours, and runs down for 7 hours ?—That would be so.

7323. But the log cannot outstrip the water in which it floats ?

(*Mr. Webster.*) Except it be for the wind.

(*Chairman.*) If it did it would be the most vivacious log that ever lived ; and if it cannot outstrip the water and is continually going up, the effect is that you have a river which does not discharge water into the sea, and is continually receiving water.

(*Witness.*) Except that the water may move with a varying velocity, the float would run past the water in one point, and the water would run past the float in another point. If there be a tendency to a greater flow of tidal water along the bed of the river, as is shown by experiment, by the greater amount of chlorine, then that has a tendency to accelerate the motion of the float up the river.

(*Chairman.*) Your main proposition, whether it goes a little higher or does not go quite so high, is, that as a matter of fact the sewage is oscillating between those two points.

(*Mr. Webster.*) I am very much obliged to your Lordship. I want your Lordship and the Commission to understand why we are introducing this matter at considerable length. The discussion which arose before the sewage was taken down to Barking at all was this. Where shall the outfall be ? I am not of course attacking the Metropolitan Board of Works. Then the advisers of the Board said, do not send us to Barking, it is much too far. There were other people who said, Barking is not far enough, and you will have to go very much further, or you will have to take the solids out of the sewage first. Then the wisdom of the time, parliamentary and otherwise, said, Barking will do. The idea at that time was that the sewage would practically be carried out to sea in one continuous stream, by always being discharged at the top of high water. I do not care a bit whether it is half a mile higher or lower. What we are seeking to prove is, that there is for a very long period of time an oscillating backwards and forwards between a point much lower than Barking, we will say Gravesend for instance, and a point higher up, of this sewage matter, and that the effect is to leave at the bottom of the river and to leave in the water that which either tends to a great nuisance or is a great nuisance. I am not at all suggesting that these float experiments prove more at present than that there is a washing backwards of sewage, and that it does not flow away readily. I quite admit that you can criticise the details of the experiments.

(*Mr. Bidder.*) If all my learned friend wants to prove is the general proposition, that the sewage does not go in one journey to sea, but oscillates backwards and forwards for an uncertain number of tides, then we are all agreed. Nobody suggests that it goes straight away to sea, but we are intending to show that the progress of the sewage to the sea is very much more rapid than anything he suggests. No one has ever suggested that the sewage would go continuously to the sea without oscillation.

7324. (*Mr. Webster to the witness.*) Did you have a float which went down continuously from Teddington to Southend, not being allowed to float up, but always going down with the ebb ?—We have had a float always going down with the ebb, and a corresponding float always coming up upon the flood.

7325. And did you take samples of the water so as to ascertain at various points at similar states of the tide what the amount of chlorine was ?—Yes, in No. 1 diagram the float was put in at Yantlet and a sample taken at the surface. In No. 1a a sample was taken at half the depth of the river, and the samples were submitted to the chemists for the purpose of ascertaining the amount of chlorine in the water (*explaining the diagram to the Commission*). There was such a powerful stream of upland water coming down the river that we could not get the float any higher up than that.

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.C.*

23 Jan. 1883.

7326. What date are you referring to?—To the 4th of November.

7327. If you refer to page 55 of the report you will find that, upon the 3rd of November, 711,100 cubic feet per minute came over Teddington Weir; and, upon the 4th of November, 627,547 cubic feet per minute came over Teddington Weir; it has been higher, and it has been down as low as 74,279; that is on page 49; so that, on this occasion, a very large quantity of upland water was coming down?—A very large quantity of upland water was coming down, although there was a tidal wave passing through that water, there was no actual tidal current backwards.

7328. (*Chairman.*) You are three days getting from Yantlet Creek to the Commercial Docks, and you get to Yantlet Creek in three days from a little above the Commercial Docks?—Yes, that is the portion where there is the largest amount of tidal water in the river; but when we get higher up than that, we get a very slow progress upward.

7329. If the sewage had been discharged at Richmond, it would have left Richmond, and never come back again?—At those points where you have a considerable amount of upland water coming in, you have a greater flow downwards.

7330. The broader the river where the discharge is, the less rapid will be the passing away of the sewage, and the longer it will oscillate?—The more tidal water it contains in proportion to upland water the longer it will oscillate.

(*Mr. Webster.*) Your Lordship is dealing only with floating.

(*Chairman.*) Yes, and not with mixing, because the more tidal water there is the more it mixes.

(*Witness.*) Yes.

7331. (*Mr. Webster.*) You have put upon the diagram the amount of chlorine in the various samples?—Yes; this is the result of analyses by Professor Way.

7332. Have you put, in the shape of a table, the effect of the mixing, taking an area, and judging by the amount of chlorine the amount of river and sea water there was?—This was only done as a check, showing that the mode of calculation we adopted was correct. The actual calculations were made from samples carefully taken up and down the river.

7333. (*Mr. Bidder.*) You say there are figures upon the plan showing the amount of chlorine; they are not upon my copy?—I said they were upon my plan. I put them on the plan before the Commission for my own use. I will lend you my plan, and you can put them on to your plan.

7334. (*Mr. Webster.*) Have you put, in the shape of a table, the effect of the mixing action with regard to the water?—I have.

7335. Will you hand in a copy of that table? *The tables were handed in.* (*See pages* 212, 213.)

7336. Are the red figures you have put on taken from Professor Way's analyses?—They are taken from Professor Way's analyses of the water going up the river upon that day.

7337. Does this table show the result of the experiments and the effect of the mixing, as you have tested it, after your calculations upon three days, the 14th and 22nd of September, and the 30th of November?—It does.

7338. I will take them separately; first, I want to know what was the condition of the Thames upon the 14th of September with regard to upland water; that I think the Commissioners will find at page 49 of your first Report; there were 83,327 cubic feet per minute passing over Teddington Weir, is that correct?—Yes.

7339. Then that would be a low period of upland water?—A moderate period, not a low period, we have had no low water this year.

7340. Taking the high water, the first thing to observe with regard to all the tables is the head note at the beginning: "The results are obtained by taking sewage as containing 10, river water 1·7, and sea water 1961 parts of chlorine in 100,000 parts. The numbers of days are calculated from the gaugings of the total flow of the River Thames on each day." The first column gives, does it not, the places to which the various mixing experiments or testings apply?—Yes, it does.

7341. Does the second column give the cross section of the river?—It does, at high water.

7342. Was this a spring or a neap tide?—That is a spring tide.

7343. The next column shows the quantity of sea water shown by analysis?—This is the quantity of sea water which is deduced from the amount of chlorine in the water, which occupies a number of feet of the section; that is to say, taking a section one foot in length it would occupy one foot in length of the whole section; at Teddington it is all river water.

(*Chairman.*) Sewage water is assumed to have chlorine in it; then it says river water and sewage combined 2518 square feet, and yet there was no chlorine.

(*Mr. Webster.*) Only the chlorine which would be represented by river water and sewage combined.

7344. (*Chairman.*) There was no chlorine in the water at all, so you infer from that that there was no sea water?—There was the chlorine in it that was due to the river water and sewage.

(*Mr. Bidder.*) Upon the head of the table it is said the sewage is assumed as containing 10 parts, and the river water 1·7: now it occurs to me that before you could arrive at any conclusion as to the proportion of river water and sewage combined, you must have arrived at some conclusion with regard to the amount of river water and the amount of sewage.

7345. (*Mr. Webster.*) We are dealing with it as a matter of comparison in each case, but with regard to the 2518 square feet, what do you assume to have been the condition as regards sewage and river water?—Our standard of 1·7 is the quantity of chlorine in the water which really comes over Teddington weir, and is assumed to be the initial quantity due to the river.

7346. (*Sir John Coode.*) Ascertained by direct experiment?—Ascertained by direct experiment from a large number of samples submitted to the chemists.

7347. 1·7 is the mean of the whole?—1·7 is the mean of the whole.

7348. (*Mr. Webster.*) That water has, when it comes over Teddington Weir, some sewage in it?—I do not say that it has any sewage in it, but it has some chlorine.

7349. (*Mr. Bidder.*) At Chiswick you find more chlorine; suppose you find three or four parts instead of 1·7, how do you know whether the extra one or two parts are caused by a very little sea water or a great deal of sewage, because either would account for it?—We have very carefully shown that, and I may say we have taken all through these experiments a standard quantity of sewage containing 10 parts in 100,000 at 5 cubic feet per head of the population; therefore we know every day what proportion that quantity bears to the volume of water coming down the river every day, and where we see that there is chlorine carried up as far as Chiswick, we have had to make a very careful calculation and show what would be the amount due to sea water, and what due to sewage, because we take it for granted that wherever sea water is carried up past the outfalls, there sewage might be carried past.

7350. (*Chairman.*) I understand from the table which is before me that there is chlorine at Chiswick and that there is a great deal more at St. Paul's Pier, and still more at Deptford, and that the inference to be drawn from that is that salt water has got up to the place where chlorine is found; is that so?—That is so.

7351. Then Mr. Bidder asked "Is not there chlorine in sewage"?—There is, but nothing like the proportion that is found in sea water. If sewage were mixed with fresh water only at any of these points, it

would not give anything like the quantity that is found there upon a particular day.

(*Mr. Webster.*) There is 196 times as much in the sea water as there is in the sewage.

(*Witness.*) There was about eight times as much river water coming down upon that day as there was sewage going in; therefore if you mix them in proportion taking eight parts of fresh water and only one part, of sewage it would not make any very great difference in the mixed volume.

7352. You would only get $1\frac{1}{4}$ to the 100,000 parts?—Between 2 and 3.

7353. A given quantity of sewage comes into the Thames every day, a given quantity of sea water comes into the Thames every day, and we will assume upon a particular day a given quantity of fresh water; the sea water contains so much chlorine, and the fresh water contains so much chlorine, and sewage is assumed to contain 10 parts of chlorine. If your Lordship assumed it all went together to a particular point you ought to be able to get approximately at the composition of the mixture at that point. Now the witness has worked backwards. Taking the sewage admittedly due to the metropolis, and coming into the river at certain points, and taking the sea water and the fresh water and ascribing to those elements the relative proportion of chlorine put down in the heading of the table, what proportion of chlorine is shown to be in the mixture that is obtained. I do not say it is shown absolutely, but it is capable of reasonably fair precision.

7354. (*Chairman.*) You say there could not be the quantity of chlorine that there was at any particular place unless the salt water had got up there?—Precisely so.

7355. (*Mr. Webster.*) Of course it almost follows that in order to make your fourth column of river water and sewage water combined, you must have an idea of the amount of river water in the river and the amount of sewage in the river?—That is so.

7356. The next column merely gives the proportion of river water and sewage to the sea water?—It is the ratio of those two columns.

7357. The next column gives the lineal distance in feet?—Yes, the next column gives the lineal distance in feet from one station to another; from Teddington to Chiswick is the first one.

7358. (*Chairman.*) At St. Paul's pier it is about eight to one?—8·4 to one is the ratio.

7359. (*Mr. Webster.*) Now the next column is the mean sectional area of river water and sewage combined; that is simply adding together the sectional area at Chiswick and Teddington, deducting the quantity occupied by sea water and dividing it by two?—Yes, that is so; it is the mean sectional area occupied by river water and sewage combined.

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.C.*

23 Jan. 1883.

7360. Now the next is, "Time occupied by fresh "water and sewage in traversing the river": how is that got out?—That is, assuming a particle of sewage were put in at Teddington, it would take 1·71 days to travel through the sectional area which is shown in the preceding column, to Chiswick.

7361. I want to know whether the 1·71 days occupied in going from Teddington to Chiswick is a calculation?—It is a calculation based upon the capacity of the section of the river, and the total quantity of water coming down the river. These tables were compiled in a very great hurry, and they are not absolutely correct as they ought to have been calculated, upon the quantity of water coming in at different parts of the river, but I have since corrected them.

7362. This table assumes that there is no fresh water coming in below Teddington?—That is so; that it all comes in at Teddington.

7363. Whereas, as a matter of fact, it comes in at various points all down the river?—It does.

7364. In the condition of spring tide, what time would it take that particle to get from Barking to Southend?—30 days.

7365. A similar calculation is due to the low water in the time table?—Yes.

7366. That, I think, makes it from Barking to Southend 31 days?—31 days.

7367. Now will you turn to the 22nd of September, and tell us what was the condition of the river upon the 22nd of September?—Upon the 22nd of September there is about 50 per cent. more upland water in the river than upon the 14th of September.

7368. The difference is between 83 and 122?—Yes, but I take the totals at the bottom; this is worked upon the 157,745 cubic feet per minute.

7369. That is, assuming the water coming down at 157,745 feet, which you have treated as all coming in at Teddington?—Yes, and I have a table here in which that is corrected. *This table was handed in.* (*See pages* 214, 215.)

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.C.*

23 Jan. 1883.

TABLE showing the EFFECT of the MIXING ACTION in the RIVER THAMES.

The results are obtained by taking sewage as containing 10, river water 1·7, and sea water 1,961 parts of chlorine in 100.000 parts. The number of days is calculated from the gaugings of the total flow of the River Thames on each day. In this case all the upland water is assumed to enter the river at Teddington.

*Mr. B. Latham, M. Inst. C.E. F.G.S., F.M.S.*

23 Jan. 1883.

TABLE showing the EFFECT of the MIXING ACTION in the RIVER THAMES.

The results are obtained by taking sewage as containing 10, river water 1·7, and sea water 1,961 parts of chlorine in 100,000 parts. In this case the upland water is apportioned to every section of the river which it enters.

LOW WATER. September 14th, 1882.

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.S.*

23 Jan. 1883.

(*Sir John Coode.*) About what is the relation of the water coming in at Teddington Weir to the whole volume of fresh water delivered into the Thames.

*Mr. Webster* stated that that would be found in the report at page 49.

7370. (*Mr. Webster.*) For the purpose of the experiment of the 22nd of September, you have given the whole of the water as 157,745 cubic feet, which is shown in the last column at page 49?—Yes.

7371. And you have again treated that as coming in at Teddington?—Yes.

7372. And you put that down as being 50 per cent. over what came in upon the 14th of September?—Yes.

7373. And upon what tide was that?—That was upon a neap tide.

7374. From Barking to Southend would take 28 days at high water?—27½ days.

7375. And from Barking to Southend at low water about 27 days?—Nearly 27½ days.

7376. Now will you please go to the 30th of November. What was the condition of the upland water upon that day?—The river was in flood upon the 30th of November.

7377. Was the tide spring or neap?—The tide was a neap tide.

7378. The total quantity of water coming into the river on that day is estimated at 557,000 cubic feet per minute as against 157,000 on the 22nd of September?—That is so.

7379. And that again you have treated as all coming in at Teddington?—Yes.

7380. How does that alter the calculation, how many days would it be from Barking to Southend under those circumstances?—14½ days at high water.

7381. And at low water?—About 13 days.

7382. Had you considered the question of mixing before you took these chlorine experiments?—Yes, these were tests taken to see whether the original samples which were taken upon these previous days would confirm our view as to this change going on all through the river.

7383. I will first take the average condition of the upland water.

(*Mr. Bidder.*) In every case the absolute quantity of sewage at Crossness where there were both outfalls coming in is less than at Barking where there was only one, and the ratio of sea water very much less although in one case you have one outfall, and at the other you have two.

(*Mr. Webster.*) You are wrong about that.

(*Sir John Coode.*) These are simply areas.

(*Mr. Bidder.*) If I understand rightly, the columns under the head of "Area of cross section occupied by "water and sewage combined," represent in each place the area of the river that will be occupied by sewage and river water at that point, and if you look at Barking and Crossness it shows that there is a less area occupied by sewage and river water at the lower place where there are two outfalls than at the upper one where there is only one.

(*Witness.*) It is simply due to this fact that there is a constriction in the cross-section of the channel at that point.

7384. (*Sir John Coode.*) Those are simply the relative areas of the river at those different points?—Yes, occupied by the different waters at these points.

7385. Apart from the composition of the water those are sectional areas of the river?—Yes.

(*Chairman.*) I am afraid also I cannot understand it.

(*Mr. Bidder.*) In addition, the next column shows the ratio of river water and sewage to salt water as diminished.

7326. (*Chairman to the witness.*) The area of the cross-section we may take to be arrived at by putting an imaginary division a foot in width across the river, and then seeing what the area of that is, not the content, but the superficial area?—Yes.

7327. Then you say, judging from the quantity of chlorine in it, which is furnished in certain proportions by fresh water, and in certain proportions by sewage, and in certain proportions by salt water, that at Barking out of a total quantity of 65,791 square feet, which you have represented as being there, there are 40,852 of sewage and river water combined?—That is so.

7328. Then when you get down to Crossness the area there is pretty nearly the same thing, but there has been a supply of more sewage and consequently more chlorine, I suppose?—There has been more sewage and a considerably larger quantity of sea water.

7389. How does that appear?—The chlorine tests show that.

7390. That is Mr. Bidder's difficulty as I understand, you have only 3,000 square or cubic feet of additional water altogether?—That is so.

7391. But you have 8,000 feet more of sea water, and you have also had an influx of sewage water?—That is quite true, but the sea water is to that extent in larger quantity there.

(*Mr. Webster.*) We are not dealing with the quantity in gallons at all, we are simply dealing with the proportion of area occupied.

7392. (*Chairman.*) In order to get the proportions, you will have to find the actual volume?—In order to get the proportion at any given time, all you want to know is the composition of the water at that time. There appears to be a constriction at Crossness by which the area is very much modified.

7393. (*Mr. Bidder.*) But your table shows a larger area?—At Crossness at low water upon the opposite table you will see that the section is absolutely smaller.

(*Chairman.*) Of course it is desirable that we should see that there is no mistake in these calculations: here again your case is not that 2317 is the right figure anywhere in particular, but that the experiments show that there is a quantity of salt water at St. Paul's Pier for example, and some at Chiswick.

(*Mr. Webster.*) That is perfectly right, but all I am going to say about this, is, that the only point for which I shall use this table is to show that there is going on between Chiswick and Southend a mixing, and that it is not right to say that that sewage which is poured out by the Metropolitan Board of Works is always going backwards and forwards, but that it is becoming diluted, and that helps to remedy the evil.

(*Chairman.*) I presume Mr. Bidder would admit that there is and must be a mixing action.

(*Mr. Bidder.*) Of course I do.

(*Mr. Webster.*) I was going on to say that your Lordship has had no statement of ours, and I do not in the least wish to make one. We are only endeavouring to see what the effect of turning out the sewage at Barking is, but we shall prove some day that due to this washing up and down, there is left deposited at the bottom of the river a large quantity of solid matter from the sewage which gives off offensive gas, and that there is also in suspension in the river a large quantity of particles which give off noxious gases and smells. I agree that it is a question of degree; it may be that we are showing a nuisance growing up so to speak, that the system has already developed in many places a very great nuisance, and in other places that it is growing up. I am not suggesting that we can prove, either mathematically or to demonstration, what the actual age of the deposit would be, but all our observations point to this, that close by the outfall you have a very large deposit, and as you recede from it, you find similar deposits of sewage matter showing that the same result which used to go on up in London years ago, and was then complained of as prejudicial to the river, is now being carried on further down.

(*Chairman.*) Let us proceed with the evidence.

7394. (*Mr. Webster to the witness.*) Taking the average condition of the river, what do you say is about the average quantity of fresh water coming in?—I take it at about 30 cubic feet per minute per square mile of drainage area.

7395. Will you point that out in your book?—The quantity coming down upon the 22nd of September would represent very nearly the average.

7396. That would represent 157,000 cubic feet a minute, of which 122,000 came over their weir?—Yes.

7397. And in dry weather what would it go down to?—In dry weather it would go down to 12 feet per minute per square mile over the whole area, from 30 to 12.

7398. That would practically speaking take the 150,000 down to 60,000.

(*Chairman.*) 5,000 square miles, multiplied by 30, would give 150,000 cubic feet a minute, or, multiplied by 12, would give 60,000.

7399. (*Mr. Webster.*) At page 49 of the Report you say that there was coming in on the 22nd of September, 157,745 cubic feet per minute?—There was.

7400. Which corresponds approximately with the 150 which my Lord worked out just now?—It does.

7401. Of that, according to your judgment, 122,461 came over Teddington Weir?—That was the actual quantity measured as coming over.

7402. The remainder coming in by the other tributaries between Teddington Weir and Barking?—That is so, only that you will see the water supply is added at the bottom, though it really belongs to the top.

7403. How low would that go down in dry times?—That, as I have said, would go down to 12 cubic feet per minute.

7404. I believe there is no day in this table which is down to a drought period?—Nothing like it.

7405. What would a flood come to?—In a maximum flood, the quantity would be 360 cubic feet per minute from a square mile.

7406. That is about twelve times as much as the average, and that though not the full amount is approximately shown on page 55, the 30th October?—That is twelve times the mean flow, and it is thirty times the minimum flow. The biggest one that we have gauged is, as you point out, upon the 30th of October.

7407. That is 1,304,000 upon the whole; is that correct?—Yes.

7408. Of which 1,053,000 comes over Teddington Weir?—That is correct.

7409. Take Barking, the northern outfall, within what time do you think on an ordinary average flow, effluent sewage is carried out to sea by both floating and mixing combined, that is to say, during an ordinary 30 cubic feet a minute period?—It would be a very much longer time as is shown by the ratio between these results.

7410. I only want to know whether you have formed a judgment as to the average time?—It is almost impossible, without experiment, to know for certain.

7411. In a dry time you can give it us by taking the 14th September?—The dryest one of these experiments was on the 14th of September.

7412. What time would it take in the dryest period?—It would be more than is represented in the table.

7413. In flood time how soon would it go out?—In flood time it would go out very quickly indeed, probably in a week.

7414. I think you have already put together, for use afterwards, some tables of temperature—what is your opinion as to the time of year or temperature at which the sewage matter would come to be noxious or unpleasant, or injurious in any way?—At over 60°, say from 65° to 70°.

7415. Do you mean the temperature of the water, or of the air?—The temperature of the water. I have taken the temperature of the water for many years in England, and I know at what temperature it would become noxious, and I can compare the result of known temperatures with the recorded state of the Thames. I beg to hand in two tables of recorded temperatures.

*The same were handed in, and are as follows:—*

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.S.*

23 Jan. 1883.

TABLE showing the NUMBER of DAYS in every MONTH when the TEMPERATURE of the THAMES WATER was above 60°, the NUMBER of DAYS it was above 65°, and the NUMBER of DAYS it was above 70°; and also the NUMBER of DAYS upon which no OBSERVATIONS were made.

* Maximum Thermometer reported to be out of order.

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.S.*

23 Jan. 1883.

7416. Where were these tables taken from?—These tables were taken from the published records at Greenwich Observatory.

7417. I think they were taken under Mr. Glashier's superintendence?—The observations originally were.

7418. Where were they taken, at the "Dreadnought," or one of the ships lying in the Thames?—The temperature of the river Thames taken in "self-registering maximum and minimum thermometers which were observed daily at 9 a.m. The thermometers enclosed in a wooden trunk were attached to the side of the 'Dreadnought' hospital ship till April 13th 1870. Commencing with January 12th 1871, they were attached to the police ship 'Scorpion,' moored in Blackwall Reach. In May 1874 the wooden trunk was shifted from the 'Scorpion' to the 'Royalist,' moored in the same place. The wooden trunk, about 5 ft. in length, and enclosed at the bottom, was firmly fixed to the side of the ship; the bottom and the sides to the height of three feet were perforated with a great number of holes, so that the water could easily flow through; the thermometers were suspended within this trunk so as to be about two feet below the surface of the water and one foot from the bottom of the trunk. On October 18th 1879, the 'Royalist' received such damage, in consequence of another vessel having come into collision with her, that she was removed on October 19th to the West India Dock, when the observations were discontinued."

7419. (*Sir John Coode.*) Did she swing at her anchors, because it is rather important to know what was the aspect of the trunk in which the thermometers were placed?—It was immersed a foot below the surface, and it will be remembered that it was running water.

7420. (*Mr. Webster.*) The first table shows that in the month of May over a series of years from 1844 to 1879 there were very few days above 60°.?—Yes.

7421. In the month of June there were a very small number above 65°, and a certain number, but not a considerable number above 70°?—Yes.

7422. In the month of July there was still more, and in the month of August also?—Yes.

7423. I think on the other side you have put down the maxima and the minima?—Upon the other side I have taken the maxima and the minima in every month throughout the various years from 1844 to 1879.

7424. With regard to the rise of the tide, is there anywhere in your reports (I believe there is), the number of feet rise?—Yes, they are given on page 39.

7425. I should like to draw attention to some matters in your report which may perhaps give rise to questions; do you say this at page 41, "The observations on the range of the tide show that low water at Southend on an average of all the tides between September and November 1882 is 1·87 feet higher than at Deptford"?—That is so.

7426. "On the 27th September 1882 low water at Deptford was 2·5 feet lower than at Southend"?—Yes; that is so.

7427. "Low water at Gravesend on the average was 1·06 feet lower than at Southend and low water at Erith 1·52 feet lower than at Southend. High water at Southend on an average of all the tides from September to November 1882 was 2·06 feet lower than high water at Deptford;" that means measured from a datum line?—Yes.

7428. From a fixed datum line not relatively to the high water itself but from a fixed datum, it is lower or higher, as the case may be?—Yes.

7429. (*Sir John Coode.*) Taking it with regard to the mean sea level which is the ordnance datum?—Precisely.

7430. I believe you wish to put in another table of temperatures?—I wish to put in another table of temperatures which gives the average taken out by Sir George Airy.

*The same was handed in, and is as follows:—*

MONTHLY MEANS, through a RANGE of THIRTY-FIVE YEARS, of the PRINCIPAL ELEMENTS of the TEMPERATURE of the WATER of the THAMES. By Sir George Biddell Airy, K.C.B., F.R.S.

| Month. | Temperature of the Water of the Thames. | Atmospheric Temperature at the Royal Observatory. | Excess of Temperature of the Thames above Atmospheric Temperature. | Diurnal Range of Temperature of the Thames. | Diurnal Range of Atmospheric Temperature. |
|---|---|---|---|---|---|
| | ° | ° | ° | ° | ° |
| January | 39·4 | 38·9 | +0·5 | 1·9 | 9·6 |
| February | 40·7 | 40·4 | +0·4 | 2·0 | 11·5 |
| March | 43·6 | 42·8 | +0·8 | 2·0 | 15·0 |
| April | 50·0 | 48·7 | +1·3 | 2·3 | 18·5 |
| May | 56·3 | 54·4 | +1·9 | 2·4 | 19·9 |
| June | 62·6 | 60·6 | +2·0 | 2·2 | 20·5 |
| July | 65·7 | 63·9 | +1·8 | 2·1 | 21·2 |
| August | 64·4 | 62·6 | +1·8 | 2·0 | 19·6 |
| September | 59·9 | 57·9 | +2·0 | 1·9 | 18·1 |
| October | 52·9 | 50·7 | +2·2 | 2·0 | 14·3 |
| November | 44·3 | 42·3 | +2·1 | 2·1 | 11·3 |
| December | 40·4 | 39·8 | +0·6 | 2·1 | 9·1 |

7431. (*Chairman.*) Why do you call particular attention to the fact that the low tide is higher at Southend than it is at Deptford?—It is a curious fact, and it shows that the river in flowing down does not obey the ordinary law of water, moving down hill because it moves up hill; it is moving by tidal impulse still, and not by the ordinary law of flowing.

(*Chairman.*) The water comes rushing down and finds itself in a narrower channel, and so goes on rising as if it struck a rock, is that how you would account for it.

(*Mr. Webster.*) But the highest point is lower down the river when it is running out. If your Lordship would kindly look at page 45 of Mr. Latham's

report, he quotes from a report in 1858 of Messrs. Bidder, Hawksley, and Bazalgette, three names well known to us, mentioning, that the diagram of the vertical range of the tides referred to was evidently in error, as low water in the lower part of the river was shown to be higher than in the upper part of the river. The recent observations, as well as others, show that the error was not made by the Government referees (the Government referees had so reported it), and that high water at, say London Bridge, is higher than high water at Sheerness, so low water in the river at London Bridge is absolutely lower than low water at Sheerness.

7432. (*To the witness.*) What is more important is this, do you draw any inference with regard to the question before us from the fact that there is a higher low tide in the lower river at Southend than there is at Deptford?—It has no very important bearing upon the question.

7433. (*Chairman.*) If it is of any importance it is worth explaining?—You must not treat the Thames as an ordinary river running down hill, but it must be dealt with as a tidal river running with a tidal impulse. In a recent inquiry the Thames has been treated altogether as an ordinary river running down hill.

(*Chairman.*) All rivers do not run down hill; the river Mississippi runs up hill. Its mouth is at a greater distance from the centre of the earth than its source is. I mention that simply as a remarkable fact.

7434. (*Mr. Webster to the witness.*) You have mentioned incidentally that the sewage is assumed to contain 10 parts in 100,000 of chlorine; what from your experiments do you find to be the amount of solid matter in sewage as discharged at Barking?—With regard to the amount of solid matter in the sewage which is discharged at Barking, I have taken the results which were published by the Metropolitan Board of Works as to the A.B.C. experiments, and I find that the quantity of solid matter as shown by those experiments made in the autumn of 1872, in which 11,672,737 gallons of sewage were treated, showed as the amount of solid matter a little over 57 grains in a gallon.

7435. (*Sir John Coode.*) Does that mean 57 grains which could be filtered off—which were in suspension?—Those experiments show clearly that there were 57 grains in a gallon in suspension in this quantity of water which was treated.

7436. (*Chairman.*) Do you know who actually made these experiments?—They were made by the late Mr. Keates.

7437. (*Sir P. Benson Maxwell.*) What are you reading from?—I am reading from my notes. Mr. Keates was the chemist to the Board. In 1872 the Metropolitan Board of Works undertook to conduct a careful series of observations under their own supervision as to the effect of the A.B.C. process in purifying the sewage of the Metropolis. The native Guano Company erected works at Crossness, and every day the quantity of sewage used at the works was tabulated and the quantity of manure produced, and the various materials were analysed, and from these reports I arrive at the conclusion that the quantity of solid matter in suspension in the sewage was 57·41 grains per gallon.

7438. (*Mr. Webster.*) Would you answer a question which was put by a member of the Commission just now. Is that solid matter which could be filtered out?—That is the solid matter in suspension, not the solid matter in solution at all.

7438*a*. (*Chairman.*) Does that mean grains in weight?—Grains in weight, a gallon of water being 70,000 grains.

7439. (*Mr. Webster.*) A gallon of sewage contains 57 grains of solid matter, not in solution but in suspension, which is really about three quarters of a grain to 1,000?—Yes.

7440. I wish to ask you what is your view of the effect upon the sewage of this washing up and down, or this oscillation backwards and forwards in the bed of the river, between above and below Barking?—As these reservoirs have been constructed at such a level that they cannot be emptied ordinarily until three hours after high water, the effect of the first of the sewage would be to flow down 12 miles, but the last would only go six miles—the next tide would bring the last outflow six miles above the outfall, the last being discharged three hours after the first.

7441. (*Chairman.*) The outlet is at half ebb?—The level of the floor of the reservoir is 2·75 above ordnance datum, and as at that level the tide in the river ordinarily is not low enough to enable it to empty until three hours after high water, it cannot empty until three hours after high water. If the water were low enough in the river to allow it, the outlets would allow it to go out quicker; it does not fall sufficiently quick ordinarily to let it get out of the reservoir until three hours after high water.

7442. During the first three hours of the ebb how far would it get out?—12·6 miles is the average range of all our experiments; the Metropolitan Board of Works have always taken it as 12 miles.

7443. The water that is flowing out during the half ebb flows out for three hours?—It does.

7444. At what rate per hour does the ebb go?—It would go two miles an hour; there would be a section of six miles of river occupied by sewage, and the next section would have no sewage in it. That which was last discharged would go down six miles, but when the tide turned that would flow back for a distance of 12 miles.

7445. (*Chairman.*) As I understand, you do not begin to discharge until half ebb?—No; they begin on the top of the flood and discharge to half ebb.

7446. Do they not discharge the whole of the ebb?—I have seen the sewage running out of the northern outfall, but in principle they do not.

7447. (*Mr. Webster.*) I was not dealing with the question of time or flow. I wanted first to know what, in your judgment, was the general effect of the sewage water being oscillated backwards and forwards, and being at the same time also mixed; has that any effect upon the deposit?—Of course all the parts which are heavier than water, being run backwards and forwards, and also coming to rest at the end of each tide, are precipitated to the bottom of the river. And this constant oscillation in hot weather is certainly most deleterious; it is not so bad at other times as in hot weather, and that is the reason I was so careful to get out the temperature tables.

7448. Of course the matter which does not deposit would be more or less impure as long as the mixing went on?—Yes.

7449. Would the fact of the sewage staying in the river in hot weather, assuming it to be not mixed, tend to make it more noxious?—Yes, because I take it that when the weather is hot, decomposition of the matter which has been deposited and decomposition of the matter held in suspension takes place, and then the tidal water is filled with the gases of decomposition, and is not capable of oxydising the impurities of the sewage.

7450. I understand you to say that the floor of the reservoir is 2·75 feet above ordnance datum?—Yes.

7451. During what hours can they discharge from the top of the flood?—Occasionally they can discharge from the top of the flood until three hours afterwards; there are times at which they can discharge to 2½, and there are cases in which the tide has dropped rapidly, and they can only discharge to two hours.

7452. Do you know whether they are able to limit the discharge to those periods of time; do you know whether they have occasionally to discharge upon the flood tide, for instance?—I know the reservoir will only hold the quantity of sewage which the sewers are capable of bringing down in two or three hours, and then when those sewers are running full for a longer period, sewage must be overflowing into the river.

7453. There is a pumping station at Grosvenor Road, or Victoria Bridge, as it is called?—There is.

*Mr. B. Latham, M. Inst. C.E., F.G.S., F.M.S.*

23 Jan. 1883.

7454. For what purpose is that?—That is for the purpose of dealing with the sewage of what is termed the Western District.

7455. To pump it so that it may go where?—So that it may go into the low level sewer, where it is taken by gravitation to Abbey Mills, and then it is pumped into the sewer going to Barking.

7456. As a matter of fact do you know whether at times that sewage has to be discharged direct into the Thames?—I know it must be so from this fact. At the time when the Metropolitan Board of Works made their outfall sewer, they proposed to deal with this district separately by deodorising works at the Kensington Canal, and when the northern outfall was more than half completed they proposed to take the western district sewage to Barking, and the consequence is that whenever the amount which the sewers are calculated to take is running in the sewers the whole of the sewage of the western district must be discharged at some other point.

7457. (*Mr. Bidder.*) Do you say that from observation, from having seen it run in?—I have seen it running in day after day at Grosvenor Road.

7458. (*Chairman.*) The sewers are calculated to carry a certain amount of water, and when they will not carry that particular amount of water there is an overflow into the Thames?—That is so.

7459. Has that anything to do with the sewer in question?

(*Mr. Webster.*) It will have.

(*Chairman.*) His observation may go to show that the sewer is not big enough for its purpose, that is all.

(*Mr. Webster.*) It will go to show that the sewers were not constructed for the burden they now have to bear, and that, as a matter of fact, the sewage has to be discharged direct.

(*Chairman.*) I think that is an important thing to bear in mind.

(*Sir John Coode.*) Is it not the fact that Sir Joseph Bazalgette admitted that to us in his first evidence, and said that the Metropolitan Board of Works were proposing a remedy, but that they were prevented from applying that remedy until this inquiry came to a close.

(*Mr. Webster.*) That was so. All I am directing my evidence to is to show what is the effect of the way in which the sewers are now working, and the effect of their incapacity to do their work.

(*Mr. Bidder.*) I admit that there are occasions, when there is a heavy rainfall, when we cannot restrain ourselves until high water. Again I say that the difficulty the Board of Works have to grapple with is, that they are discharging sewage in Barking under these difficulties, and what I am pointing out is only that the Commissioners may see that there is a growing need.

(*Chairman.*) Your witness went to show that the western sewage went into the river; that is material as showing that they very likely calculated their areas upon an erroneous footing, because they are putting in sewage at a higher point than was intended.

(*Witness.*) What the Board proposed was to increase the capacity of the reservoirs 50 per cent., that is quite clear from their last published report to Parliament.

(*Mr. Webster.*) You are not now proposing the method in which you would remedy this, but I would ask you this, would any further increase of holding space down at Barking remedy, in your opinion, the evils that exist in turning out the sewage at Barking?—It would not.

(*Mr. Webster.*) There are other ways of dealing with it, for instance, such as taking out the solids, which I do not propose to go into at present.

Adjourned to to-morrow at half-past twelve.

---

# SIXTEENTH DAY.

## Wednesday, 24th January 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANCOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.

W. POLE, Esq., F.R.S., *Secretary.*

Mr. BALDWIN LATHAM, Mem. Inst. C.E., further examined.

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883.

(*Mr. Lumley Smith.*) I shall be glad if your Lordship would allow me, before we pass to a fresh head, to ask one or two questions with regard to certain matters which passed yesterday, to which we wish to add one or two observations.

7460. (*To the witness.*) I believe, returning for a moment to the float experiments, that on some occasions deep floats were used, and on others surface floats?—That is so.

7461. I believe you have one general observation, it is not a matter of detail, but you have one general observation to make with regard to the comparative velocity of progression of the deep float and the surface float, have you not?—I have.

7462. What is the conclusion you come to from the experiments with regard to the deep and the surface floats?—It will be found at page 37 of my Report. I found that, in ascending the river, on the average, the surface floats moved with a less velocity than the deep floats, but on descending the river the surface floats moved with the greater velocity; we give the figures in the Report.

7463. Have you any theory with regard to the explanation of that fact, or is it merely a matter of observation which you think ought to be recorded?—I have simply recorded the fact. I explained yesterday the probable cause of it.

(*Chairman.*) Need we trouble ourselves with the theory of it; will it assist us in our investigation?

(*Mr. Lumley Smith.*) Only to this extent, that my learned friend having suggested yesterday that there might be a discrepancy with regard to observations made at the same time, it was possible that the difference in the nature of the floats might account for it.

7464. (*To the witness.*) Now, passing on, I think you have given, have you not, at page 38 of your Report, which has been handed in, a table of the difference between ebb and flow at certain places mentioned in the book?—I have. That I took from the diagrams of the vertical range of the tides.

7465. The times of ebb and flow vary at different points on the river?—The times of flood and ebb vary, the flood being shorter, and the ebb being longer throughout the river; but all these times vary from one point to the other; they are nearer together in the lower part of the river, and more unequal in the upper part.

7466. At Teddington there are only two hours of flood and ten hours of ebb; at Southend, on the other hand, there are 6h. 3m. of flood and 6h. 22m. of ebb?—That is so.

7467. Does that vary with regard to spring tides and neap tides, or is it the average of both?—This is the average of a number of months' experiments.

7468. You wish to draw attention also to the fact, which you will find in your book on page 39, that the tides are actually rising; that is the conclusion you have come to?—There is an increased range of tides in the Thames to what there was formerly.

7469. Can you give any particular place at which the comparison can be taken?—I have shown it at page 39.

7470. I see that Mr. Redman's paper takes the range of tides in the Pool. What would be the nearest corresponding point that you have taken?—Deptford will be the nearest of our tidal stations to the Pool.

7471. Having taken Deptford, I wish to draw your attention to the fact, if you look at Mr. Redman's table, that although in 1800 it was 18 feet in the Pool, and rose gradually until 1874 when it was 22 feet, yet in 1882 Deptford does not seem to have been higher?—Those are the extremes.

7472. Mr. Redman's are extremes?—Yes; and if you compare my centre table at page 40 with that, you will find it shows that it has rather gone on in an increasing range from 1874; that the range at Deptford is 23·8 feet upon the 28th of September tide.

7473. This is a matter which I presume is independent of the embankment, or any local matter of that kind; have you any theory upon that matter?—I think it is due in a great measure to the gradual deepening of the river from dredging operations.

7474. That causes the tidal wave at ebb and flow to become greater?—It tends to accelerate its flow, and to make it become greater.

7475. From these observations of the tide, I think you deduce, do you not, the mean tide level?—Yes; from all the observations of three months we have deduced the mean tide level in the river from Southend to Deptford, and then we give the mean tide level at Teddington, taking the number of tides when there is an average quantity of water coming down the river.

7476. The mean tide level at Deptford is how much above ordnance datum?—It is 1·98.

7477. At Teddington Lock it is 11, and at Erith Pier 1·96?—And at Gravesend Pier it is 1·94, and at Southend Pier 1·89.

7478. Teddington had to a certain extent to be calculated?—Teddington had to be dealt with separately, as the volume of river water materially affects the question.

7479. With regard to the outfalls, which of those would most nearly correspond with the mean tide at the outfalls?—The mean would be between Erith and Deptford.

7480. Between 1·96 and 1·98?—Yes.

7481. The mean tide is half way between high water and low water?—The mean tide is half way between high and low water.

7482. Would that vary with different tides, or is that fairly constant?—It varies somewhat between neaps and springs; but this is the average, taking three months' observations. I ought to mention that I find that that level does not agree with the level given by the Metropolitan Board of Works.

7483. You might tell us, perhaps, what the Metropolitan Board put their level at?—In the Report of Messrs. Bidder, Hawksby, and Bazalgette, of the 6th of April 1858, there is a diagram at the end which shows the mean tide level to be 1·5 half tide. It also shows the mean high water to be 11 feet above ordnance datum, and the mean low water to be 7 feet below. Now the mean of those figures shows that the 1·5 is incorrect, and that it ought to be 2 feet exactly.

7484. From the figures they give, the 11 and the 7, it will come to 2, which you find to be more correct?—Yes.

*The Chairman* intimated that these minutiæ were not material to the issue before the Commission.

7485. (*Mr. Lumley Smith.*) Now one general observation with regard to the effect of the tide. I believe the total distance from the Nore up to the outfall is 36 miles, is it not?—It is 36¼ miles.

7486. You ascertained by your float experiments what the ordinary range of a float was on a tide?—Yes.

7487. What may you take that roughly at?—Upon a flood tide the average of all results is 12·6 miles, on the ebb 12·64 miles.

7488. (*Chairman.*) Do you mean the distance it went?—The average of all the ranges up and down. Of all the ranges up it would be 12 miles and $\frac{6}{10}$ths, the average of all the flows down is 12$\frac{64}{100}$ths.

(*Mr. Lumley Smith.*) Taking one particular tide.

7489. (*Chairman.*) There is only a difference of $\frac{4}{100}$ths?—Yes.

(*Chairman.*) That amounts to a furlong practically.

7490. (*Mr. Lumley Smith.*) The distance from the outfall to the Nore is practically three times the range of the tide?—Yes, in round numbers.

7491. Then, assuming the sewage to be carried along in the Thames as a float would be, sewage poured out upon the top of the tide at Barking would get down a distance of 12 miles?—12·6 miles upon the average.

7492. Assuming the sea water to enter the Nore at the same rate at which the float was found to travel up upon the same tide, the water would come from the sea a distance of 12 miles?—12·6 miles.

7493. Then there would be an intermediate 12 miles into which in the course of a single tide no fresh water would come from one end and no sea water would come from the other?—That is so.

7494. What is the effect of the tidal wave, in your judgment, with regard to water being forced up the river?—The tidal wave acts by impulse upon the body of the water which is in the mouth of the river and propels it up the river, so that if there were no mixing action going on, the water which is in the lower part of the river at low water would be identical with the water at the end of the range of the tide, 12·6 miles higher up, at high water.

7495. May I take it that the mixing action is due to currents and all kinds of things?—The mixing action is principally due to currents; it is due to the fact that, while the ebb is still running down, the flood is running up the sides of the river.

7496. (*Sir John Coode.*) Have you made any deep-water observations in order to ascertain whether the early flood makes up at the bottom much before it appears upon the surface?—We intended to do so, but the weather prevented us making the experiment.

7497. Then you have no fact to go upon with regard to that?—No; we only made the chlorine experiments. We intended to have done so by means of current meters.

7498. (*Mr. Lumley Smith.*) Apart from mixing, you think the mass of 12 miles of river would be simply forced up and then returned again?—There would be a body of water constantly oscillating backwards and forwards in the Thames in one tide, no change taking place.

7499. (*Chairman.*) One twenty-fifth of a mile in 12 miles would make it about one per 300; would not the result of that be that it would take 300 tides before anything starting would have got to the end of the first division of 12 miles?—That would be correct, assuming that the float observations represented the true flow of the river, but they represent really an exaggerated flow.

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883.

7500. There are two tides in the day; so it would take about two years according to that, supposing there were no mixing, before any water or log, or float, or anything else put in at Crossness would be in the sea finally; that is so, is it not?—Yes; assuming there is no mixing, and assuming there is no displacement, that would be true.

(*Mr. Lumley Smith.*) Your Lordship gets the $\frac{1}{25}$th by subtracting the 12·64 from the 12·60.

(*Chairman.*) Yes; but bear in mind that the more mixing you make the more you extenuate the case of the Board. On the other hand, the more you facilitate its getting up towards the upper part of the river the more you extenuate the mixing, I suppose.

(*Witness.*) The mixing acts in two ways; if there were no mixing action we should not have the sea water up at Chiswick.

7500*a*. (*Mr. Lumley Smith.*) And you not only get the mixing action, but you get a current down the river which in flood times is very important?—If there were no mixing action going on, still the fresh water coming in would drive out by degrees the volume of water in the river.

7501. Apart from that, do you find from your investigation whether the extent to which the salt water gets up the river varies at different times of the year?—Yes; it is a well accepted maxim that as the amount of upland water decreases, so the salt water line advances up the river.

7502. Then in a wet season you find the salt water does not get so far up as in a dry season?—In a wet season it is shown (upon the 30th of November in one of the tables we have put in) that salt water does not get up anything like the distance it does at other times, because you will see at Deptford upon that day there is no sea water at all.

7503. Which table are you referring to?—The third table at low water of the 30th of November, but if you refer to the same period at low water upon the 14th of September you find that there is a measurable quantity of sea water in the river at that point.

7504. Then generally we may take it, it seems common sense almost, that in a wet season the salt water does not find its way so far up as in a dry season. Now, with regard to the rate at which the tidal wave advances, is there any ratio which that bears to the current?—The tidal wave advances according to a law which was discovered by a committee of the British Association many years ago, and that is, that in a rectangular channel it is equal to the square root of half the depth. That is, that the wave would move with a velocity equal to that which a solid body would acquire in falling a distance equal to half the depth of the channel.

7505. It varies with the channel; but is there any rough ratio that you can tell us?—In the Thames we find, taking the area from Southend upwards, that the velocity of travel of the tidal wave is fifteen times as great as that of the ordinary flow of the tidal current.

7506. The average of the flow of the upland water has been taken from the table, has it not?—Yes. I have given you a calculation as to the average and the actual result. Upon the 22nd of September, when we get the tidal observations, they nearly correspond with the actual flow of the Thames.

7507. Comparing the rest of the year with the average, which is longest; the time when the upland water exceeds the average, or the time when the upland water is below the average?—The longest period is when the tendency is for the upland water to diminish in flow. Floods rise very rapidly, but the subsidence of the water is very slow afterwards, so that the period when the upland water is diminishing is longer than that in which it is increasing.

7508. That does not quite answer my question as to during what portion of the year the river is above its average and when it is below?—Of course there are exceptions, but, as a rule, in the autumn and spring it would be above; but there are well-known instances of summer floods in the Thames.

7509. The time when the float observations were taken was a time when there was a considerable flood coming in, was there not?—Principally; there has not been a dry period this year. I, myself, have been carrying on gaugings, for a particular purpose, for a number of years past, and I know that during the whole of the past year we have had an abnormally large quantity of water.

7510. I believe that yesterday, with regard to the chlorine test, you said you had had some figures furnished you by Professor Way?—Yes; and checked by Dr. Tidy.

7511. The table of chlorine observations supplied by Professor Way will be found at page 4 of the print which I am handing in. These were the figures to which you alluded yesterday as having been supplied to you?—Those are the results supplied to me by Professor Way and Dr. Tidy as to the amount of chlorine in different points which were taken out as the bases of the calculation as to the mixing action. (*The following table was handed in.*)

(*From the Analyses of Prof. J. T. Way.*)

| Locality. | Chlorine in 100,000 Parts of Water. 14th September 1882. | | Chlorine in 100,000 Parts of Water. 22nd September 1882. | | Chlorine in 100,000 Parts of Water. 30th November 1882. | |
|---|---|---|---|---|---|---|
| | High Water. | Low Water. | High Water. | Low Water. | High Water. | Low Water. |
| Teddington | 1·70 | 1·70 | 1·70 | 1·73 | 1·70 | 1·70 |
| Chiswick | 4·70 | 1.90 | 1·92 | 1·85 | 1·95 | 1·75 |
| St. Paul's Pier | 210·70 | 4·10 | 89·00 | 2·45 | 2·80 | 1·90 |
| Deptford | 438·00 | 49·00 | 311·00 | 28·80 | 20·00 | 1·85 |
| North Woolwich | 671·00 | 180·00 | 581·00 | 162·00 | 118·25 | 2·10 |
| Barking | 745·00 | 319·00 | 638·00 | 280·00 | 152·25 | 5·00 |
| Crossness | 918·00 | 470·00 | 754·00 | 440·00 | 276·00 | 18·75 |
| Erith | 1,031·00 | 530·00 | 836·00 | 555·00 | 314·25 | 83·75 |
| Gravesend | 1,502,00 | 1,058·00 | 1,352·00 | 1,062·00 | None taken. | None taken. |
| Southend | 1,931·00 | 1,765·00 | 1,891·00 | 1,816·00 | 1,785·00 | 1,522·5 |
| Margate | — | — | — | — | 1,770·00 | 1,735·5 |

7512. I take it as the explanation of these tests that, on three distinct days, upon the 14th of September, the 22nd of September, and the 30th of November, samples of water were taken at the places mentioned in that list?—They were.

7513. Namely, at Teddington, Chiswick, St. Paul's Pier, Deptford, North Woolwich, Barking, Crossness, Erith, Gravesend, Southend, and Margate?—They were, at high and low water.

7514. And those samples were submitted to Professor Way for his analysis?—Yes.

7515. Of course, with regard to his analysis, he would be the proper person to explain it, and not you?—He can better explain it.

7516. Are you able to explain, or shall I keep that for him, the way in which, from knowing the amount of chlorine in a sample of water at a particular place, you can form any conclusion as to the amount of sea water present as compared with the river water and sewage?—That has been entirely done by myself and others who have assisted me in the matter.

7517. Will you explain that to the Commission. May I take it, first of all, to clear the ground for the moment, that if the amount of chlorine in a particular fluid is known, and also if the amount of chlorine in another fluid is known, you can tell the amount of chlorine there ought to be in the mixture?—Certainly.

7518. Take it inversely, that if you know the amount of chlorine in one of the fluids, and the amount of chlorine in another, if you put your dipper into a pailful of the mixture, and find out how much chlorine there is in it you can tell the relative proportions of the mixture?—Yes.

7519. Here we have to deal with three fluids?—Yes.

7520. (*Chairman.*) If there is one fluid in which there are 20 grains of chlorine, and one in which there are 10, and you mix them in equal proportions you will find 30 grains in the mixture, and 15 if you take an equal volume of each ?—I have taken two cases, to simplify the matter, to show it synthetically; first, by building up a composition of a certain quality, that is if we take one volume of sea water, which we know contains 1,961 parts of chlorine in 100,000 parts, and if we take nine volumes of river water, each of which contain 1·7 parts, those nine volumes will equal 15·3, which, added to the 1,961, give 1,976·3; that is the amount of chlorine in 10 volumes, the one volume of sea water and the nine of fresh water. If we divide that by 10 it shows at once that the volume of chlorine in one volume of mixed water is a tenth part of that, or 197·63; that is showing what the composition of the fluid is synthetically. Now the chemist supplies us with an analysis of the mixed water.

7521. (*Chairman.*) You know the volume of the water you have put in ?—We have given you that, we have built that up.

7522. And in one volume of the mixture you ought to find 197·63 ?—We do. Then the chemist gives us one volume containing 197·63, and we have to find out in what ratio that is mixed. In order to do that you will observe I adopt the following formula. Let A equal the chlorine in sea water, which is 1,961 in the 100,000; let B equal the chlorine in the river water, which is 1·7 in 100,000; let C equal the chlorine in the mixed water, which is the amount the chemist gives us. The other two factors we also know from the composition of this water, which in this instance is 197·63 in 100,000 parts. To find out what quantity of river water there is mixed in the volume of sea water, if we take A minus C, and divide it by C minus B, we get the exact result, that there are nine volumes, as shown by these figures, we have built up before, that corresponds with the nine volumes we originally added to the mixture, proving that both synthetically and analytically it is correct. That is taking a very simple compound, but where we have three separate fluids mixing, it can be dealt with in exactly the same way. In this case I have built up a compound consisting of one volume of sea water, which contains 1,961 parts of chlorine, one volume of sewage, which contains 10 parts in 100,000, and I have taken 10 volumes of river water, each of which contains 1·7, or the 10 contain 17. If we add them up together it gives us 1,988 parts of chlorine in 12 volumes; if we divide that by 12 we get 165·66 parts of chlorine in one volume of the mixture. We know there that we have one volume of sewage containing 10, and we have 10 volumes of river water containing 17. If we divide the 27 by the 11 it shows us that in mixed river and sewage we have 2·45, that is the amount of chlorine in one volume of mixed sewage and river water. Now if we take the formula which we used in the first example and instead of calling B the amount of chlorine in the mixed river and sewage water we call it the amount of chlorine in the mixed water, and repeat the same operation, you will find from the figures that we have a mixture of 11 volumes, that is 11 volumes of mixed sewage and river water combined with one of sea water; so that the chemist supplying us with the figures, 165·66, we know for certain that that quantity of chlorine, were we dealing with fluids of known specific quality, could only be combined in those proportions to produce this result.

7523. (*Chairman.*) The object in these calculations is to find the proportion of chlorine attributable to sea water, and thereby to find out what proportion of sea water is attributable to the mixture ?—The object is by means of the chlorine to find out the proportion of sea water and river water and sewage in every part of the channel.

7524. (*Sir John Coode.*) And inasmuch as the sea water in the upper part of the river must have passed the outfall, that sea water must contain a portion of sewage ?

(*Witness.*) That is so.

7525. (*Chairman.*) Your object is to show that sewage is flowing up the river, and that is done by showing that the sea water gets up, and it cannot get up without its companion sewage; and in order to show that the sea water gets up, you find the quantity of chlorine in the water and you find that there is more than is attributable to the land water ?—Yes. I have worked here at great length a more elaborate mode showing how this formula is deduced; I beg to hand that in as giving examples (*handing in the same. See Appendix* U.).

7526. (*Mr. Lumley Smith.*) May I take it generally, that the object of the chlorine experiments is not to distinguish between the amount of river water and the amount of sewage, but to distinguish between what is sea water and what is not sea water ?—It is. You see the ultimate effect of it is this; if we show that there is only a certain portion in the whole river which is occupied by this mixture of river water and sewage (that is the channel which has every day to be displaced by the amount of upland water coming down), instead of having to displace the whole volume of the river, it has only to displace this smaller quantity, and, consequently, it goes out so much the faster, that is the measure of the mixing action.

7527. I suppose the importance of these observations increases down the river; it is useless taking them up above the bridge ?—Of course, they are much more important down the river, and the tables show to an enormous extent that the lower down the river you go, the greater the effect of the mixing action, because if the mixing action did not take place there would be the same amount of river and sea water all the way down.

7528. (*Dr. De Chaumont.*) In making these calculations, do you assume that the proportion of sewage and river water is the same at all points ?—We took the actual volume that we knew came down the river upon the same day; we took a standard of sewage by taking five cubic feet per head of the population, because you may take it that if there was anything that would increase the amount of sewage there would still be the same amount of chlorine going in, although in a larger volume. The population contributes the same proportion of sewage every day, although if it rained, it would go into a larger quantity of water.

7529. (*Mr. Lumley Smith.*) You know the fresh water coming over Teddington Weir ?—I know the quantity of fresh water coming over Teddington Weir on each of those days, and all through the district.

7530. And you know the amount of fresh water that comes in every day ?—We do, at every point of the river.

7531. Do you also know the amount of the sewage that goes into the river every day ?—We do, in that way, the standard sewage.

7532. You assume the mixture of river water and sewage to be of the same proportion as the daily flow of the water and sewage ?—That is so.

7533. As you know the amount of chlorine in each, it is easy to see what is the amount of chlorine in those two mixed ?—That is so.

7534. Those calculations are made upon the assumption that the sewage and fresh water are mixed in those ordinary proportions ?—Yes.

7535. In your judgment, is it fair to assume that they are mixed in those ordinary proportions ?—It is not only fair, but it is absolutely correct, because if there happens to be a larger amount of river water coming down it is measured in river water, whilst there is the same measure of chlorine coming from the population.

7536. You first of all mix the sewage and fresh water so as to make one fluid ?—Yes, to make one fluid.

7537. Then that mingles with the sea ?—That mingles with the sea; and I do it for this reason, that there may be changes going on in the sewage itself, but there can be no changes going on in the amount of chlorine in the sewage which may be taken as permanent; therefore, we take the amount of chlorine as indestructible.

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883.

7538. Then that reduces it to the two fluids mixing?—That is so.

7539. You assume the proportions of the two so as to reduce it to one fluid, and then you consider the sea water. As you know the amount of chlorine in each, it becomes very easy to gather from each sample how much is river water, how much is sewage, and how much sea water?—Certainly.

7540. (*Sir John Coode.*) You have ascertained the amount of fresh water coming over Teddington Weir every day during these observations?—Not only at Teddington Weir, but of all the tributaries down the river.

7541. Have you had gauges at the different places?—In 50 different places.

7542. So you have ascertained the quantity of water every day coming into the river?—Yes, with the exception of the 284 square miles which I stated were $\frac{1}{15}$th part of the whole drainage area of the Thames.

7543. (*Mr. Lumley Smith.*) Now the amount of chlorine, I think you told us yesterday, in the sea water is very large comparatively, is it not? I think you gave us the figure of 1,961 parts in 100,000?—Yes.

7544. The amount in fresh water is how much?—1·7.

7545. And the amount in sewage is how much?—10 in 100,000.

7546. Could you tell us how much you have taken as the chlorine in a combination of sewage and fresh water?—That varies in different parts of the river. I have a table here which shows that; it has not been printed, but I will put it in. That shows the quantity at every station. Below Barking it is constant, but above it is less.

7547. When you are getting down below Barking, and into the part where there is a good deal of salt water, would it make any difference to your observations to know how much is fresh water and how much is sewage?—No.

7548. For the purpose of ascertaining the relative amount of sea water and non-sea water, is it material to distinguish between the sewage and the fresh water?—No, it is not.

(*Mr. Bidder.*) In the lower reaches, where the proportion of chlorine reaches hundreds of grains, the relative proportions of fresh water and fresh water and sewage are not important.

(*Witness.*) In the other tables we have estimated river water—not Southend water,—but in the later tables you will see there is very little difference in the ratios. If you compare those with the columns in the ratios, you will find that that is taking not sea water but river water, and comparing it with Southend water. This table, as I say, shows the amount of chlorine taken all the way down the river.

(*The same was handed in, and was as follows*):—

TABLE showing the Amount of Chlorine in 100,000 Parts in the component Volume of River Water and Sewage combined at the following Places on the Thames, when the Samples were taken.

| | September 14th. | | September 22nd | | November 30th. | |
|---|---|---|---|---|---|---|
| | High Water. | Low Water. | High Water. | Low Water. | High Water. | Low Water. |
| Teddington - - | 1·7 | 1·7 | 1·7 | 1·7 | 1·7 | 1·7 |
| Chiswick - - | 1·7 | 1·7 | 1·7 | 1·7 | 1·7 | 1·7 |
| St. Paul's Pier - | 2·11 | 2·11 | 2·01 | 2·01 | 1·7 | 1·7 |
| Deptford - - | 2·34 | 2·34 | 2·17 | 2·17 | 1·77 | 1·7 |
| N. Woolwich - - | 2·58 | 2·58 | 2·35 | 2·35 | 1·86 | 1·7 |
| Barking - - | 2·67 | 2·67 | 2·42 | 2·42 | 1·90 | 1·90 |
| Crossness - - | 2·67 | 2·67 | 2·42 | 2·42 | 1·90 | 1·90 |
| Erith - - | 2·67 | 2·67 | 2·42 | 2·42 | 1·90 | 1·90 |
| Gravesend - - | 2·67 | 2·67 | 2·42 | 2·42 | 1·90 | 1·90 |
| Southend - - | 2·67 | 2·67 | 2·42 | 2·42 | 1·90 | 1·90 |

7549. I may take it that, when you get down the river, it is immaterial, for the purpose of ascertaining the amount of sea water, whether you take the amount of chlorine in what is non-sea water or in what is taken as river water and sewage?—It makes very little difference to the results.

7550. (*Chairman.*) What is the explanation of the table you have handed in? On the 14th of September the chlorine at high water and low water at Southend you put down at 2·67, and it is the same at Barking. On September the 22nd it is 2·42 at Southend, and on November the 30th it is 1·90 at Southend, can that be attributable to the difference in the quantity of the fresh river water?—That is so. There is 50 per cent. more water coming down upon the 22nd than upon the 14th, producing greater dilution in the mixture; and upon the 30th November the river was in flood.

7551. Was the quantity of flood or land water so great as to cause there being about 40 per cent. less chlorine at Southend?—Yes; the proportions on that particular day, if you will refer to the last page of my Report, are 757,000 cubic feet upon the 30th of November, and upon the 22nd of September 150,000 cubic feet per minute.

7552. Does that water bear any comparison to the volume at Southend?—No; this is the amount of chlorine in the mixed river and sewage water.

7553. For the chlorine to vary, the mixture must vary?—So it did.

7554. That is to say, there would be less chlorine; when there was 1·90, there was more land water?—Yes, there was more land water.

7555. Would its volume when it got to Southend be anything like two-fifths of the whole volume?—This is exactly worked out in proportion to the volume coming down each day.

7556. I should have thought the highest flood going over Teddington Weir would be scarcely appreciable at Southend?—It is distinctly; you will see by Table III. that it goes at low water in 13 days right away from Teddington, whereas it takes 38 days in dry weather.

(*Mr. Bidder.*) I cannot help thinking that there is some misunderstanding between your lordship and the witness as to the purpose of this table, and I will tell you why. If you look at page 4 of the tables of Professor Way's analysis of the amount of chlorine in 100,000 parts, upon the very same days the figures are so very different that I am sure this table does not mean the absolute quantity of chlorine.

(*Witness.*) I did not say it did.

(*Mr. Bidder.*) But I gathered from his lordship's question that there must be some misunderstanding as to what the table purported to show.

(*Chairman.*) I thought that if you took out any quantity of water upon one of the days named, you would have 2·67 parts of chlorine in it; and if you took it out upon another day you would have 1·90.

(*Mr. Bidder.*) If you refer to page 4 of the table of Professor Way's analysis, which relates to the very same days and the same places, you will see that that cannot be so.

(*Witness.*) I have told you what it is; that it is the chlorine in the mixed river water and sewage; it is not the chlorine in the river, you must deduct the chlorine in sea water from the actual chlorine observed in the water. My table shows the amount of chlorine in the river and sewage water combined together, and the difference between one table and the other would represent how much is made up of sea water, that being the difference, and it would show you the ratio of the sea water to the mixture.

7557. (*Chairman.*) I understand you do not dip your bucket into the water at Sheerness and try what is there then?—That is the way we originally arrived at it; then we treat it by analysis and bring out how much is really due to river water and sewage only.

(*Mr. Bidder.*) I fancy it comes to this; upon the 14th of September, at Southend, a sample bucket of water was taken, and it was found to contain at high

water 1,931 grains of chloride of sodium; that was the actual observation. Then from other considerations they drew the inference that only one part in 100, or something of that kind, of that was river and sewage water, and consequently they drew the second inference that if their first inference was correct there would be that amount of chlorine in the river and sewage water, is that right?

(*Witness.*) I have already told you that it is based upon the inference that there are five cubic feet of sewage per head of the population, and that there is a given volume of fresh water coming down the river, and that by mixing them in the proportions named you get at those results, except where you deal with the district above Barking. We see that the sea water is carried up to a certain point, and that there, there ceases to be so much chlorine. Chiswick may be taken as the vanishing point, at Barking there is the full volume, and if you take the mean between the two, it would show that there is only half the chlorine due to sewage in that part of the river which is observed at Barking.

7558. (*Mr. Lumley Smith.*) Professor Way's table is taken from actual analyses of water taken from the river?—Yes.

7559. The table that you have handed in is from that table?—This table shows the quantity of river water in the mixture all the way up the river, it is calculated from the volume of water in the river.

(*Chairman.*) What is the general conclusion which the witness draws from this? Does he say that in ordinary tides, for instance, such a part of the total volume of water at Chiswick is sea water; at Vauxhall Bridge such a proportion is sea water, and so on. If he could tell us that, it would assist us towards considering how much sewage water had got up there.

7560. (*Mr. Lumley Smith to the Witness.*) Are you able to answer that?—Yes, I show you that; I show you at every point up the river how much sea water there is.

7561. (*Chairman.*) What table is that shown by?—The table I put in yesterday.

7562. That is to say, at Chiswick, $\frac{1}{700}$th part of the volume was sea water?—Yes.

7563. At St. Paul's Pier about $\frac{1}{3}$th was sea water, is that so?—We give you the exact ratio of the mixture in the fifth column.

7564. When you get to Erith you find about an equal quantity of sea water and of the mixture of sewage and fresh water?—Yes, that is so.

7565. (*Mr. Lumley Smith.*) That gives you, as shown in your table, what, in your opinion, is the actual ratio of sea water and non sea water at those different points of the river?—Yes, it does; but this is, of course, upon the assumption which I explained yesterday. I made the calculations upon the basis that all the water came in at Teddington; it was a much longer work to take it out at all the points coming down the river, but I have now had that done.

7566. These tables which you now hand in carry out the same calculation as those you handed in yesterday, except that it is much more accurately worked out?—Yes.

7567. What is the conclusion at which you have arrived?—That it increases the number of days which it takes the sewage to get out, but it does not affect it all below Barking; it affects it more above, in the upper reaches of the river. (*See table inserted after* Q. 7369.)

*Mr. B. Latham M. Inst. C.E.*

24 Jan. 1883.

TABLES showing the effect of the mixing action in the River Thames. These results are obtained by taking sewage as containing 10, river water 1·7, and sea water 1,961 parts of chlorine in 100,000 parts.

SEPTEMBER 14TH, 1882.

*Mr. B. Latham. M. Inst. C.E.*

24 Jan. 1883.

7568. Do you draw any conclusion as to the number of days in which the sewage will get out to sea?—Yes.

7569. Will you tell us, generally, what conclusion you draw with regard to that?—The conclusion we draw from this amended table is this, that, if we take the high water on the 14th of September, and start at Deptford, it would take 41 days to get out; and, taking low water, it would be, roundly, 40 days. Then, upon the 22nd. of course it goes much quicker, there being a much larger quantity of water in the river, and it takes, roundly, 34 days from Deptford, at high water, and at low water, 31 days. Upon the 30th of November it takes, roundly, 16 days at high water, and it takes 12 days at low water. In a very dry time of course, it would go out very much more slowly, as is shown by these results.

7570. When you speak of the high water upon a particular day, you mean that the sewage which is discharged from the outfalls upon that particular day at the top of the tide would get to the sea in the time that you have mentioned?—Yes. I have taken Deptford, because, as a fact, the sewage is discharged for about three hours, and it is brought up again, as a rule, to this point upon the top of the returning tide.

7571. By taking the high tide you take the first sewage which is poured in?—I take the point at which the sewage arrives, after it has been discharged, upon the next tide.

7572. When you speak of high water, that is when the sewage was discharged at high water when the reservoir was opened?—Sewage discharged at high water and down to half tide.

7573. The sewage discharged at the intermediate time would, I presume, arrive at the intermediate time at the sea?—It would arrive at an intermediate time in the lower part of the river, and at a higher point upon the return.

7574. In arriving at the time when the sewage would get to the sea, have you considered both the displacement and the mixing?—Yes; displacement is a very slow operation indeed; the displacement is simply due to the upland water pushing the water out of the river.

7575. And that, as my Lord pointed out, would take a long time, if that alone had to get it into the sea, but in flood time it would have a considerable effect?—In flood time the flood has effect by displacing more quickly, and also the mixing action being greater.

7576. Have you calculated the difference between the mixing action in flood and dry times?—I show the difference between flood and dry times to be 30 times, taking the whole basin of the Thames.

7577. Are you speaking of the whole of the water?—No; I am comparing 12 feet per square mile of the whole drainage area with 360 feet per square mile in flood time.

7578. Now, I want to ask you a question or two about some matters which may go to cause pollution in the River Thames. I believe there was published in the published reports, and, indeed, we have heard from Sir Joseph Bazalgette, what was the amount of sewage which was proposed to be taken in the sewers and the amount of rainfall also?—Yes, that has been stated.

7579. I believe you have made some calculations for the purpose of showing that the population has outgrown the population which the sewers were estimated to be able to accommodate?—That is so.

7580. Have you also made some calculations which tend to show that the amount of rainfall which the sewers can take is below what really gets into them?

(*Sir John Coode.*) But Sir Joseph Bazalgette has told the Commission that the Metropolitan Board of Works were prepared to spend a million and a half of money to remedy this evil.

(*Mr. Lumley Smith.*) I hope to be able to show from calculations we shall produce that a great quantity of sewage, and rain mixed with sewage, does habitually go into the river in London, which would, I submit, appear to be material, in considering how far the present system of sewerage is sufficient, or how far it requires amendment. I further intend to show that pollution takes place partly from the outfalls and partly from what happens above the outfalls.

(*Chairman.*) Certainly, that is a very proper matter of inquiry.

(*Sir John Coode.*) These remarks apply to Pimlico and Battersea.

(*Mr. Lumley Smith.*) Yes.

(*Mr. Bidder.*) But surely, with submission, the question is not what our system is, and what our population is, and whether it is calculated for that population or not; but, being what it is, what effect it has upon the river at this point.

(*Chairman.*) I suppose it is a sort of evidence against you, in this way, that you would not have wasted your means in making larger sewers than you thought necessary, that is if you thought that sewers for two millions only were necessary.

(*Mr. Bidder.*) But, my Lord, even supposing we assume that the Metropolitan Board of Works thought accommodation for two millions was sufficient, and we have now to provide for four millions, how does that affect the question; the question is, what is its effect upon the river?

(*Chairman.*) They propose to show that the thing being what it is it is not sufficient, and they propose to show it in this way, that you, yourselves, thought that all you would have to provide for was two millions, and you provided for two millions, and now there are four millions, and, therefore, you have not provided what you would have done if you had known what would happen.

(*Mr. Bidder.*) But, if I may say so, is not the question as a matter of fact, what is the effect of the sewage system upon the river Thames, is not that the point?

(*Chairman.*) You, yourselves, will show that you would not have done then what you have done now, if you had known then what you know now. I think when Sir Joseph Bazalgette comes he will be asked that question.

(*Sir John Coode.*) We have to inquire into the facts as they now exist.

7581. (*Mr. Lumley Smith to the witness.*) In order to take it a little systematically, will you tell me, if you please, what you take to be the area drained by the sewers of the metropolis. I believe you first of all take your figures, do you not, from the report of the Metropolitan Board of Works of the 31st of December 1874?—Yes, that is so; the report to Parliament.

7582. Will you tell me what is the area stated to be draining into the Northern high level sewers?—The area draining into the Northern high level sewer is stated to be 10 square miles, into the Middle level sewer 17½ miles, into the low level 11 miles, and into the western district 14½ miles, making a total of 53 square miles.

7583. What is the area stated to be draining into the sewers upon the south side?—In the south the area draining into the high level sewer is 20 miles, and into the low level sewer 20 miles, making a total of 40 square miles.

7584. That would make a gross total of 93 square miles?—Yes, a total of 93 square miles, I should mention that there was another figure given before, in what is known as the "Mud inquiry," which made the south 42, and the north 51; it was the same total, but it made the incidence different.

7585. You have checked it yourself, have you not, from the Ordnance map?—From the Ordnance Survey.

7586. Can you give us the actual area by calculation, which is under the jurisdiction of the Board of Works?—Yes, the area upon the north of the Thames I have divided into land and water and foreshore. The area in Middlesex upon the north is 49·19 square miles, and in Kent ·64.

7587. Making a total of land of how much?—Of 49·83, and of water and foreshore in Middlesex 1·45 square miles, and in Kent ·40, making a total of 1·85.

7588. That makes a total area north of the Thames of how much?—Of 51·68 square miles within the jurisdiction of the Metropolitan Board of Works.

7589. And south of the Thames?—South of the Thames we have of land 37·34 square miles in Surrey; 30·70 square miles in Kent; making a total of land 68·04 square miles; of water and foreshore ·99 in Surrey, and 1·39 in Kent; making a total of 2·38, or a total upon the south side of 70·42 square miles.

7590. That gives a grand total of land of 117·87; and of water and foreshore of 4·23; making a total of 123·1 square miles?—Yes.

7591. I believe that agrees pretty accurately, does it not, with the Registrar General's returns?—That agrees very nearly with the Registrar General's returns, which work out from the acreage given in these returns at 122 square miles.

(*Mr. Bidder.*) Is "area under the jurisdiction of the Board" the same thing as "area drained by the Board?"

7592. (*Mr. Lumley Smith.*) I am coming to that. *To the witness.*) I see your total area of land, 117·87, agrees with the Metropolitan Board of Works' reports; what do they make it?—They give it in one report as 117½, and in another at 118.

7593. As the amount drained is given as 93 square miles, there is, apparently, a difference between the amount drained and the amount under their jurisdiction of 24½ miles?—Yes, that is of land only, deducting the foreshore and water.

7594. Then they have within their jurisdiction, which would have to come into their system, about 24½ miles?—Yes, principally upon the south side of the river.

7595. I presume it was considered unnecessary to drain that part?—I do not know as to that.

7596. In addition to the natural drainage from the 93 miles, are there any other matters which come into the sewers of the metropolis?—Yes.

7597. First of all, I will direct your attention to the natural streams, do the natural streams affect the question?—Yes. Before the metropolis became what it now is, the whole district was divided into valleys, which had natural streams within them. In the Metropolitan district, most of the streams in the valley lines have been converted into sewers. The upper end of the streams terminated in districts outside the metropolis, so that whatever portion of the district outside the metropolis is in their watershed must naturally drain into the Metropolitan Board sewers, such, for example, as the Effra and the Stamford Brook.

7598. These rivers have their source outside the Metropolitan district, so that the water which enters the streams outside the metropolitan district has to be conveyed through the metropolitan sewers to the river Thames?—It has.

7599. I do not know whether there is any means of estimating the amount of water that comes in from these brooks?—It can be estimated, whatever it is, it has to be conveyed, it cannot be limited to any specific quantity; whatever rain falls, and flows down the stream must go into the sewer; it may be 2½ inches in 24 hours, or it may be very much less.

7600. All that has to be added to what is naturally taken by the sewers?—Yes.

7601. Then there are other districts which have to be added to the metropolitan districts?—Yes; those are districts which, for the purpose of rainfall, comprise a part of Chiswick, ·13 of a square mile; Ealing detached, which is Bedford Park, ·88 of a square mile; Acton, 3·52 square miles; Hornsey, ·64 of a square mile; Willesden, ·75 of a square mile; making, upon the north, 6·92 square miles. Then part of Croydon, Upper Norwood, ·46, and Beckenham, 1·05; making 1·51 miles in the south; making a total outside the metropolis of 8·43 square miles. The whole of the rainfall of that 8·43 square miles has to pass into the metropolitan sewers, as it can go no where else.

7602. Are those legally drained into the metropolitan system, or is it a matter of dispute; I believe some Act of Parliament has been acquired?—That is as to the rainfall only, but in addition to that there are those districts which drain their sewage into the metropolitan sewers.

7603. Those districts may be built over, or they may not be; can you give us any idea of the amount which comes from those districts?—In 1871 an Act of Parliament was passed, which enabled Hornsey to drain in, that is take the whole of the district. That part of Hornsey I have been dealing with is only the part of the district which drains the rainfall into the sewer, but in 1871 an Act was passed to admit the sewage of this district, and they were limited in the Act to pass 500 cubic feet a minute, that is at the rate of four and a half millions cubic feet in 24 hours into the metropolitan sewers. In 1878 an Act was passed to enable Beckenham Tongue, which contains 675 acres, to drain in; and in 1874, under another Act, the South Hornsey Local Board district was drained, and by a recent decision a very large part of Acton was admitted.

7604. I believe the admission of Acton is the result of litigation, is it not?—It has been, but I believe it is settled now.

7605. (*Mr. Bidder.*) I believe an injunction has been granted against the Local Board of Acton, prohibiting any future extension of drainage into the Board of Works sewers, while it authorised that which had existed previously?—That is so; that all the existing drainage goes in, but none in the future can go in. I have also got at the population of those places. The population of Hornsey in 1881 was 22,474; and of South Hornsey 14,587, part of Acton is estimated at 14,000, part of Croydon at 3,000, and part of Beckenham at 5,000, making a total of 59,061.

7606. (*Mr. Lumley Smith.*) Then you have treated these districts as having all to be drained into these sewers?—They have to be drained into these sewers.

7607. Do you find anywhere in the Board's reports anything to show that this was contemplated?—No; it has been reported to Parliament that these powers have been taken from time to time, but were not in the original scheme.

7608. (*Chairman.*) Would the natural water, the rainfall, from these districts, have gone through the sewers even if the sewage had not?—The rainfall is in addition to what I have been speaking of, it must go through; it is its natural outlet, but that does not apply to Hornsey. A very small part of it would have gone into the sewers by gravitation.

7609. Would some of it have gone into the Lea?—Some of it would have gone into the Lea; the largest portion.

7610. (*Mr. Lumley Smith.*) The privilege of sending sewage down the metropolitan sewers is one thing which could not have been done without the authorization of Parliament, but you yourself said that there were certain places not sewered to the metropolis, the rain water of which nevertheless must find its way through the sewers. Do those additional places which you mention, which have now the privilege of draining their sewage through the metropolitan sewers, add not merely their sewage to the sewers but their rainfall, or was the rain water there before?—In Chiswick no sewage goes in, but the natural rainfall only. At Norwood, both the sewage of the district and the rainfall go in.

7611. Formerly the rainfall went in and not the sewage?—Yes. At Ealing (Bedford Park) both the rainfall and the sewage go in.

7612. Have they had the privilege of draining their sewage into the sewers?—That has been added.

7613. What is the consequence of that; that the rainfall goes into the sewers which it did not do before, or merely that sewage goes in which did not go in before?—The rainfall went in before, and now the sewage goes in in addition. In Hornsey only a portion of the rainfall and all the sewage goes in.

7614. It is not to be taken from what you say that the sewers now drain additionally, if one may say so, all those places; they take their sewage now, but they drained them, or many of them, before of the

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883.

rainfall?—Small portions of them. Beckenham takes no rain water in, only the sewage and the rain water which falls upon the roofs of the houses, but in the case of the other districts, the 8·4 square miles, all the rainfall has to go into the sewers.

7615. (*Mr. Bidder.*) Would you mind adding one thing to that, that it always had to go in?—It always had to go in; it is part of the natural drainage area.

7616. (*Mr. Lumley Smith.*) Now if you please, with regard to population; do you find in any Report of the Metropolitan Board what the population provided for was?—Yes.

7617. Will you tell us where you find that?—In the report that you have before you of the 6th of April 1858, page 41.

7618. Whose report is that?—It is the report of Messrs. Bidder, Hawksley, and Bazalgette.

7619. What do you find stated there with regard to the provision made for future population?—In the north the population provided for was 2,353,900, and in the south 1,094,600, making a total of 3,448,500.

7620. That represents, as I understand, the population to be provided for in the sewers?—That represents the population which the sewers were designed to provide for.

7621. Not the existing population of the day, but the future population?—Not the existing population of the day, but the future population as then estimated.

7622. I believe there is a district called the Western District?—There is such a district.

7623. What do you include in that?—It is shown on one of the plans in this report I have just alluded to, coloured green.

7624. What district is it roughly?—It is a district which comprised 14½ square miles, as described in the report of 21st January, 1854.

7625. Is there anything which shows that in that estimated future population of 3,448,500 the western population is included?—There is nothing to show that, but these figures contemplated the whole population upon the north and the whole population upon the south.

7626. Have you anything to show or can you give us any reason for supposing that that was to include the drainage of the western district?—There is a report of Sir Joseph Bazalgette and Colonel Haywood of the 21st January 1854, which brings it in.

7627. What is stated there with regard to the prospective population to the north?—They had dealt separately with that, and they pointed out that as being 2,013,200 as against the 2,353,900 for the whole of the north.

7628. Does that report give the population for the Brentford and Acton Divisions?—Yes; at that time the Board evidently contemplated going much higher up the river.

7629. What did they make the population of the western area?—553,900.

7630. That would make the population to the north with the western area, 2,567,100?—That is so.

7631. That is a little larger than is given in the report of Messrs. Bidder, Hawksley, and Bazalgette?—Yes, because it included a rather larger district.

7632. Is it fair to conclude that the prospective population given in 1858 included the western district?—It included the western district.

7633. We will come to the district as we find it to be; you have taken the census of 1881, have you not?—I have taken the census of 1881, and I find that by that census the population of the north was 2,543,999, and of the south it was 1,283,448, making a total of 3,832,441.

7634. Therefore at the time of the census do you find an excess of population in the metropolis beyond the figures mentioned in the provisional estimate?—Yes, I find that there was an excess in the metropolis upon the north of 195,093, and upon the south of 188,448 beyond what was contemplated.

7635. Ought anything to be added for the district outside?—Yes, you must add to the population I have already given 50,000 for the districts outside draining into the metropolitan district.

7636. (*Chairman.*) As far as the sewage goes does it appear whether you have calculated it upon this hitting the exact amount or whether they had left a margin?—As regards mere sewage it is based upon these figures in a way which I will presently explain.

7637. (*Mr. Lumley Smith.*) Adding so much for the districts outside the metropolis, what have you got for the figures of the population in 1881?—If you add 50,000 of course it shows you that there is in round numbers nearly half a million of people more in the metropolis and the districts outside draining into these sewers than the sewers were contemplated to deal with.

7638. Is that what you find from the census or is that your estimate for the present year 1882?—That is calculated to the middle of 1882.

7639. What did you find it was at the time of the census?—433,000.

7640. Now you have given us, have you not, the population of the Metropolitan Board's district?—I have.

7641. A distinction seems to exist between the space drained and the whole district?—Yes, there is such.

7642. Will those figures require any correction for the purpose of making them the figures of the district drained as distinguished from the district under the jurisdiction of the board?—Yes; not so much on the north, but on the south more so; and I will here put in two tables, one which shows the district of the Registrar-General which coincides more nearly with the district which is actually drained, and a second table in which I have put in the population of the Metropolitan Board district itself from 1871 to 1881, the figures of which have been arrived at from the census periods. Then I give a calculation taking the same rate of increase as was found to exist in the metropolis between 1871 and 1881, and continuing it, by which I give you the probable population every year up to 1901, both upon the north and south of the river.

*The following tables were handed in.*

POPULATION within the LIMITS of the REGISTRAR-GENERAL'S DISTRICT* on the NORTH and SOUTH of the METROPOLIS.

| Year. | North London. | South London. |
|---|---|---|
| 30 June 1871 | 2,292,597 | 973,978 |
| „ „ 1872 | 2,317,777 | 1,000,491 |
| „ „ 1873 | 2,343,233 | 1,027,726 |
| „ „ 1874 | 2,368,968 | 1,055,701 |
| „ „ 1875 | 2,394,986 | 1,084,439 |
| „ „ 1876 | 2,421,290 | 1,113,958 |
| „ „ 1877 | 2,447,882 | 1,144,282 |
| „ „ 1878 | 2,474,766 | 1,175,429 |
| „ „ 1879 | 2,501,946 | 1,207,427 |
| „ „ 1880 | 2,529,425 | 1,240,294 |
| „ „ 1881 | 2,557,205 | 1,274,058 |

* The population of this district has been used in all calculations, it more nearly coincides with the area actually sewered.

ESTIMATED PROSPECTIVE POPULATION from 1882 to 1901, at the same RATE of INCREASE.

| Year. | North London. | South London. |

BASIC FIGURES of the CENSUS RETURNS employed in these COMPUTATIONS.

| | | | |
|---|---|---|---|
| 3 April 1871 | 2,285,672 | 979,333 | 3,265,005 |
| 4 April 1881 | 2,548,993 | 1,283,448 | 3,832,441 |

7643. Now, is it the fact that the limits of the Registrar-General's district coincide more nearly with the district actually sewered?—They do.

7644. You can tell us in a moment what is the definition of the district of the Registrar-General; is that defined by Act of Parliament and is it what is known as the Bills of Mortality district?—It is what they call the Bills of Mortality district.

7645. And that corresponds more nearly with the district sewered?—It corresponds more nearly with the district sewered than the Metropolitan Board's district population itself does.

7646. I see that in 1881 the population exceeds the figure that you gave us of the population in the Metropolitan Board's district; will you compare the figure you gave us in 1881 in the Board's district with the Registrar General's district?—There is a very much larger area outside the Metropolis on the north which comes into the sewers, while on the south there is a very large area which is not drained, and when you compare the two statements of population upon the south you will find that in the Registrar General's district they are much less than in the Metropolitan district.

7647. You say that upon the north it is very much the same thing—that the whole of the district is sewered?—It is not only sewered but the district outside is sewered—there is a small margin, but it is all more or less built upon at the present time.

7648. According to your calculation the population in the middle of 1882 exceeds what the sewers have been provided for by about half a million?—Yes.

7649. If the present increase is continued (that is on the north only) there would be an increase of 100,000 in the present year; is that so?—No, that is taking both north and south.

7650. And in 20 years' time there will be an increase of how much?—A very considerable increase.

(*Sir John Coode.*) The witness makes it 5,360,000, taking the figures in the first Table.

7651. (*Mr. Lumley Smith.*) So much for the population. Now can you tell us the increase in the rateable value of the Metropolis between 1856 and 1882; what was the rateable value in 1856?—The rateable value has increased from about 11,000,000 to 27,000,000 of money in round numbers.

7652. Now a question or two about the rainfall; what amount of rainfall was provided to be dealt with?—The amount of rainfall to be dealt with is shown in that Report I have quoted, and it is also given in the Government Returns; on the north it was 28,500,000 cubic feet in the day, and upon the south 17,250,000 cubic feet in the day.

7653. That you find by the Report as what was to be provided for?—Yes, it is at page 44 of the same Report and it is also given in the Report to Parliament of the 31st December 1874.

7654. I think it was also stated what quantity as regards the areas should be taken?—It was stated that a quarter of an inch of rain flowing off the area was to be taken.

7655. That agrees with what was stated by Sir Joseph Bazalgette in his answer to question 9 upon the first day of this inquiry?—Yes.

7656. Do you find in that Report during what period the quarter of an inch is estimated for?—The quarter of an inch is estimated as flowing off uniformly throughout the 24 hours, or in round numbers one-hundredth of an inch an hour during the maximum period of the flow of the sewage.

7657. Is the time of maximum flow of the sewage given?—Yes, that has been given; being calculated at half the total volume (which was taken at five cubic feet per head) flowing off in six hours.

7658. The sewage flows unevenly; we may take it as half flowing off in six hours, and half in the remaining 18 hours?—That was what was stated in the Metropolitan Board of Works report, but the Government Referees' report took half the flow as passing off in eight hours.

7659. What does a quarter of an inch a mile represent?—580,800 cubic feet.

7660. Then if you divide that figure that was given you as the rainfall from the north of the metropolis, for which provision was made by that quantity, what is the result?—If you divide the 28,500,000 cubic feet, which is stated to be the quantity of rain that the sewers are to carry by the 580,800 cubic feet, that being the quantity which a quarter of an inch of rain flowing off would give, that shows that the area is 49·07 square miles.

7661. Is that quarter of an inch of rainfall a matter of calculation?—It is a matter of calculation. Having got the quantity the sewers are to carry and the time in which they are to carry it, it is only a matter of calculation as to the area.

7662. Then treating the south in the same way, what do you find to be the result?—Treating the south in the same way, we have the quantity there given as the amount of rain which is to be admitted to the sewers at 17,250,000 cubic feet; that divided by the 580,800 shows that the area must have been 29·7 square miles.

7663. (*Chairman.*) And what is the actual area?—The actual area which has been given in the reports I have referred to was 40 square miles and 53 square miles on the north.

7664. (*Mr. Lumley Smith.*) It appears that the provision made for the south was for a very much smaller district than should have been provided for assuming that depth of rain to be taken?—Yes.

7665. But I believe you do find that a reason is given in the report for taking a smaller amount?—I find in some of the earlier reports that a reason is given for taking a smaller amount.

7666. What is that reason?—That from the northern high level and from the high level district upon th

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883

south instead of taking a quarter of an inch, they took only an eighth of an inch of rain.

7667. Can you give us the reference in Sir Joseph Bazalgette's report to that?—It is the report of the 13th of April 1856 to the Metropolitan Board of Works. It is stated that, "In the thinly populated "suburbs only one half the quantity of rain for "which provision is made in the more crowded dis- "tricts is to flow of."

7668. In the south it may be that the larger area was contemplated, but the smaller amount has been taken; that is to say, one eighth instead of a quarter?—One eighth has been taken in both these high levels, because if you take the eighth of an inch from the high level area it practically comes to the 40 square miles which they have admitted in the south.

7669. It comes to this, that a quarter of an inch is taken in the 24 hours, except in the high levels where one eighth has been taken?—Yes.

7670. That is independent, is it not, of the outside district?—That is entirely independent of the outside district. It is based merely upon the volume which they have given us which the sewers are to carry, which is clearly calculated only upon the metropolitan area itself.

(*Chairman to Mr. Lumley Smith.*) This tends to show two things, does it not. First of all, that the sewers must be discharging, perhaps at the time when the tide is not ebbing, but more especially it shows that the overflows carry the sewage and everything direct into the river.

(*Witness.*) That is really the bearing of the whole question, that it leads to the pollution of the higher portions of the river, and that by discharging more frequently at other points into the river there is an accumulation of the sewage which would not otherwise take place.

(*Mr. Lumley Smith.*) When a storm outlet opens out comes the sewage and storm water together.

(*Chairman.*) That raises quite a different question as to whether they have gone low enough, but it also raises this question—whether they must not separate their rain drains from their sewage drains?

(*Mr. Lumley Smith.*) That is so; that is when you come to the remedy.

(*Mr. Bidder.*) As regards the storm outlets I should point out that the storm outlets were part of the original scheme, and were made with the intention that they should come into operation; and when they do come into operation, which is when there is heavy rain, their operation must be necessarily that which has been described. That was their intended operation, and whether it is a nuisance or not is another matter. That there should be storm overflows is no unforeseen matter.

(*Chairman.*) No, we understood that from Sir Joseph Bazalgette. He explained the whole thing as well as anything could be done, I thought.

7671. (*Mr. Lumley Smith to the Witness.*) Now you say the Board put down the time of the maximum flow of the sewers at six hours; you put it at eight, do you not?—I say the Board in their calculation take six hours for the maximum flow. The gaugings of the sewers, published by the Government Referees in their Report in 1857, showed that half of it flowed off in eight hours instead of six. Recent experiments, however, show that half of the whole volume of the sewage flows off in nine hours.

7672. (*Chairman.*) Supposing that the reservoirs were entirely empty, and you started quite fresh, half the sewage put in would reach them in nine hours?—Half the sewage of the Metropolis, as distinguished from rainfall, would reach them in nine hours of maximum flow.

7673. (*Col. Ewart.*) At the two outfalls?—These calculations are based upon the southern outfall. We do not know anything at all of the northern.

7674. (*Chairman.*) The sewage is perpetually coming into the sewers of course in the whole 24 hours?—That is so.

(*Mr. Lumley Smith.*) But the evidence is that there is very little at night.

(*Mr. Bidder.*) Your Lordship will find that there are certain periods of the day in which there is a great flow of sewage, and other periods of the day in which the flow of sewage is very small. Sir Joseph Bazalgette was quite right in laying down his plans. He assumed that the contrast would be so great that he would have to deal with half the sewage in six hours of the day, and, consequently, he must make his sewers proportionately big, but in point of fact it turns out that there are nine hours over which that flow is distributed, so that he has rather made his sewers too big than too small.

(*Witness.*) I may say that I have paid great attention to the rates of fluctuation in sewers, and knowing that a table was published in the Mud Inquiry of the gaugings of the sewage flowing out at Crossness I was able to work out from my experience what this table of gaugings which was put in showed; and I may say, it showed this fact, that where a district is a very large district the sewage from the more distant parts requires a much longer time to get down to the point of outfall than from those which are nearer to it.

7675. (*Chairman.*) That is to say a longer proportion of time?—A longer time, because if there is a district 18 miles away from an outfall the sewage from that district will take a longer time than if it were a mile away.

7676. Would it take 18 times as long; that is to say a longer proportionate time?—A longer proportionate time.

7677. Would 18 times as long be all, or would it take a longer proportionate time, would it take 24 hours?—No.

7678. Would it take a time proportionate to its distance only?—I would point out with regard to this inequality in the flow of the sewage throughout the day, that there is one hour of the day when the quantity flowing is at the rate of three times what would be the mean flow: that hour in places in the metropolis which are close to the outfall would occur between 11 and 12 in the morning, and there is a slight rise as you come nearer meal times in the evening; and in the early hours of the morning in the district close to the outfall the lowest period of flow would be about three o'clock. Now, as these districts are more or less distant, it so happens that the maximum flow of the sewage from a district which is very remote may arrive at the outfall at the time of minimum flow from the district which is close by. Therefore it tends to equalise the flow during the day, and consequently you do not get that violent rate of fluctuation in the larger districts where you have a long system of sewerage. Taking the gaugings in the Mud Inquiry, I find it is equal to deferring the sewage of the south side 11 hours, that is to say, it takes the sewage of the most remote district 11 hours to get there while the sewage of other districts close to takes no great length of time: that brings the minimum period to 6 o'clock in the morning, and it brings the maximum flow to 6 in the evening. That is the reason of the difference. It is not that there is less sewage, for when you come to deal with the whole volume of the day there is no difference, but the distance equalizes the flow.

7679. (*Sir John Coode.*) That would be dependent upon the distance of the most distant part of the system from the outlet and upon the gradient?—That is so.

7680. You do not say that would affect the whole system equally?—I have been able to tabulate a statement which shows that fact. This is a Table which I have worked out for the metropolis, and the figures in this Table really show the per-centages, that is, they show the total volume of sewage flowing in gallons or feet in the day; if you multiply them by the decimal given and divide them by 100 the result will show the quantity of sewage flowing per minute at any hour in the day in the district.

*The table was handed in, and is as follows:*

The TOTAL QUANTITY of SEWAGE FLOWING per DAY multiplied by the following DECIMALS, and divided by 100, will give the QUANTITY FLOWING per MINUTE at any HOUR.

*Note.*—The decimal to be used for the mean quantity per minute = ·0695.

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883.

7681. You do not lay that down as a rule applicable everywhere, do you?—That would apply all over the country to sewers where there is no leakage.

7682. (*Mr. Lumley Smith.*) It occurs to one immediately that during the whole time of the maximum flow of the sewage there would be less room in the sewers for the rainfall?—Yes, during the maximum flow there is less room for the rainfall.

7683. Have you calculated what rainfall there is room for when the maximum flow of the sewage is passing through the sewers?—I have taken the figures as given. I have a Table by means of which we show to what extent the sewage has been deferred, that is to say, how many hours it has been deferred from the most distant parts.

7684. In your judgment is that likely to cause the overflows to be brought more into requisition than had been estimated and provided for?—No; on the contrary it tends to equalize the flow; there is really more room in the sewers than had been calculated; that is to say, there is more room in the sewers during what would otherwise have been the maximum period.

7685. Practically it comes to this, that if all the sewage had had to come down in six hours they would have been running fuller than if it had to come down in nine hours?—That is so of course.

7686. Now with regard to the effect of this system upon the water having to be expelled through the storm overflows; have you anything to tell us as to that?—If the sewers are not large enough to take the sewage and the quantity of rain which they have been designed to take for a greater number of days or periods or times than was contemplated, then the overflows must act; and whatever brings those overflows into operation for a greater number of times must lead to a greater degree of pollution of the river in the higher parts, because it takes very much longer to get out the higher the sewage is put into the river.

7687. Looking at what we have got from Sir Joseph Bazalgette, and from the reports of the Board, as to the amount of sewage that actually goes out at Crossness and Barking, the sewage is there, I presume, composed partly of rainfall and partly of sewage proper?—Yes.

7688. Comparing Crossness and Barking what difference do you find in the composition?—I have analysed the quantities which have been put in by Sir Joseph Bazalgette, and have divided them into sewage proper and depth of rain flowing off the district. (*The following Table was handed in.*)

| Year. | Rainfall. | South of Thames. 40 square miles. Depth of Rain reported to flow off by Sewers at Crossness. | North of Thames. 54 square miles. Depth of Rain reported to flow off by Sewers at Barking. |
|---|---|---|---|
| | Inches. | Inches. | Inches. |
| 1875 | 29·28 | 18·3 | 0·4 |
| 1876 | 28·90 | 15·7 | 1·0 |
| 1877 | 29·26 | 21·4 | 3·6 |
| 1878 | 29·26 | 23·1 | 3·4 |
| 1879 | 30·23 | 28·9 | 7·4 |
| 1880 | 34·11 | 25·4 | 5·3 |
| 1881 | 24·30 | 20·8 | 5·3 |

I begin in the year 1875, as previously to that the Western sewage was pumped into the river at Cremorne, and this is the first year when it is was conveyed to both the outfalls—to Barking upon the north and Crossness upon the south. Here you will observe I have taken the area upon the south of the Thames at 40 square miles, and upon the north at 54. The way in which I arrived at these figures of depth of rain flowing off was by taking the actual figures which were given to us by Sir Joseph Bazalgette, and which are combined in another table, which I will now hand in. (*The same was handed in and was as follows.*)

| Years. | Crossness. Rainfall. | Population Registrar-General's District. | Total Quantity of Sewage per Annum. | Quantity of Sewage per Day. | Quantity of Sewage per Head per Day. |
|---|---|---|---|---|---|
| | | | Gallons. | Gallons. | Gallons. |
| 1875 - - | 29·28 | 1,084,439 | 23,505,775,239 | 64,399,384 | 59·4 |
| 1876 - - | 28·90 | 1,113,958 | 22,370,124,831 | 61,120,559 | 54·9 |
| 1877 - - | 29·26 | 1,144,282 | 26,008,009,706 | 71,254,821 | 62·2 |
| 1878 - - | 29·26 | 1,175,429 | 27,317,822,594 | 74,843,349 | 63·7 |
| 1879 - - | 30·23 | 1,207,427 | 31,065,965,556 | 85,112,234 | 70·5 |
| 1880 - - | 34·11 | 1,240,294 | 29,533,247,494 | 80,691,933 | 65·0 |
| 1881 - - | 24·30 | 1,274,058 | 27,223,090,538 | 74,583,809 | 58·5 |
| 1882 to Nov. 24th | — | 1,308,738 | 21,043,864,091 | 64,158,122 | 49·0 |

| Years. | Barking. Rainfall. | Population Registrar-General's District. | Total Quantity of Sewage per Annum. | Quantity of Sewage per Day. | Quantity of Sewage per Head per Day. |
|---|---|---|---|---|---|

In the fourth columns are the actual figures given to us in gallons flowing off at Crossness and Barking; the fifth columns show the actual figures in gallons per day as having flowed into the river on the north and south.

7689. Your figures in the column headed, "Total "quantity of sewage per annum" you get from the figures given by the Metropolitan Board of Works?—Yes, that is the actual figure given to us.

7690. Then by division you get the amount per day?—By dividing that by 365 days and in leap years by 366 days, it gives us the number of gallons each day.

7691. Then how do you get the "Quantity of sewage per head per day"?—By dividing it by the population shown in the third column.

7692. How do you get the rainfall so as to separate the rainfall which flows off into the sewers from the sewage?—I have taken the water supply of the district in 1881 as shown to be supplied to the population.

7693. The actual water supply to the population appears from the returns of the water companies?—It does, they give us the quantity they supply on the south and on the north of the river.

7694. Is it fair to take the number of feet of water supplied by the companies as equal in sewage to the quantity that goes out at the outfalls?—Yes, that approximates pretty nearly to the five cubic feet per head which is the quantity given by the Metropolitan Board of Works.

7695. Then in order to calculate the quantity of sewage it is not necessary to calculate the solid matter?—No, it is not.

7696. By taking off the quantity of water supplied by the companies you get the quantity that goes off at the outfalls due to rain or other matter?—Yes, by deducting the actual quantity of water supplied that shows the balance, and by dividing that out we come

to the actual depth in inches which flows off the area, which is given at the head of the columns.

7697. (*Prof. Williamson.*) I do not understand the difference between the numbers under the heading "Quantity of sewage per head per day at Crossness" and those under the corresponding heading for Barking, how are they so different?—I cannot understand myself how there should be such an enormous difference, but they are the figures given to us.

7698. At Barking it is 5 cubic feet per head, but in the other case it is something like 8?—There is no doubt that on the south, out of the 50 gallons per head per day, there are 30 gallons of water supply and 20 gallons of leakage per day into the sewers.

7699. (*Chairman.*) What becomes of it?—It gets into the sewers from the subsoil and takes the place of sewage and rain, it becomes, as it were, an agricultural drain for draining the land.

7,700. You mean that the sewer drains more than is put into it?—It admits the water from the subsoil to a large extent.

7,701. (*Sir J. Coode.*) Practically one is double the other?—That is so. Those are the actual figures that are given to us, and we have given you every figure to show how we have arrived at it. If you diminish the population upon the south (which we say is incorrect) you must increase the volume per head, and if you diminish it upon the north you must increase the volume per head.

7,702. (*Mr. Lumley Smith.*) It comes to this, that although upon the south you have a smaller area, or rather a more thinly populated area?—Notwithstanding that we have a smaller area, and we have half of that area in which it was only contemplated to take one eighth of an inch instead of a quarter of an inch, yet we have the singular fact that the tables shew, in depth of rain, a relative ratio of 5, 6, and 7 times, and even in one case 40 times as much rain flowing off on the south side as on the north side.

7703. One word with regard to the thinness of the population. Is the principle of that this, that where you have a district which is thoroughly built over, all the rain falls on roof or pavement, and passes down the sewer; but where you have a district which is thinly populated all the water does not go into the sewers—is that the principle upon which the eighth is taken instead of the quarter?—I do not know, but it is a well-known meteorological fact that the higher the district the more rain falls on it, and, therefore, one would have thought it more necessary to make the larger provision for the higher district. Another reason may be that in a thinly populated district a smaller quantity of rain water would dilute the sewage to a given point, while in a thickly populated district it would require a larger amount of rainfall to dilute it to the same extent.

7704. But is it the fact that if you have a district completely built over all the water goes straight into the sewers?—Yes, certainly.

7705. But where you have a district which is partly houses and partly fields and gardens, then the same result does not follow?—In an agricultural district a very large proportion would go into the ordinary water-courses.

7706. Now the conclusion come to is this—that the amount of water, I prefer not to use the word "rainfall," or rather the amount of water and sewage which goes off at Crossness, is very much larger than the water which goes off at Barking?—Very much larger—as appears by the calculations.

7707. (*Chairman.*) Do you mean a larger absolute quantity?—A large quantity per square mile—larger in depth over the area. Your Lordship will see in the first column we give the actual rainfall, which is the average of the three gauges at Crossness. Then we give you the actual depth of rain flowing off upon the south, and the actual depth flowing off upon the north. In 1875 there are 29·28 inches of rain falling upon the south; 18·3 inches of that flowed off either by flowing into the sewers or by percolation into the sewers. Upon the north it was only four-tenths of an inch that actually flowed off. The difference between those figures, after deducting what had been really evaporated, must have come into the river at a higher point than the outfalls.

7708. Then it would seem that either the water, which ought to get out at Barking, is liberated by the storm overflows, or that the sewers which discharge at Crossness have been tapping underground springs?—It would seem to me that both causes operated.

7709. What is your reason for thinking that all the sewage which should go to Barking does not go there?—My reason for thinking so is because of these gaugings, which were taken some years ago at Crossness, and which were put in at length in the Mud Inquiry.

(*Chairman.*) What was that "Mud Inquiry;" was it as to whether there was any obstruction in the Thames?

(*Mr. Michael.*) It was as to whether banks of mud were formed by the sewage.

(*Mr. Lumley Smith.*) And formed an obstruction to the navigation.

(*Witness.*) This observation was taken in 1876 in very dry weather, when there was no rain at all.

7710. (*Mr. Lumley Smith.*) Taking a dry season would show that what has been discharged would not come from rain?—That would show that what had been discharged then could not possibly come from rain. The result of this showed that on the 12th July 1876, the quantity discharged in gallons at Crossness on this particular day was 52,256,223 gallons, and that was an excessively dry period; in fact the month of July was one of the smallest rainfalls that was ever recorded—there had been no rain from the 24th of June to the 6th of July. On that day, at 8 p.m., the sixteenth of an inch fell, and ·01 upon the 7th, and ·02 upon the 8th, and then upon the 12th these experiments commenced, and were conducted throughout the day. Then from the table of population in 1876 you will see that there is a little over 1,000,000 of population and 52,000,000 gallons of sewage, so that you have 50 gallons per head, that is 30 of sewage proper and 20 of leakage, as I have already stated.

7711. (*Chairman.*) When you say "sewage proper" you mean what was intended to go into the sewers?—And what is included as the water supply to the district, which is known.

7712. And then there was no storm overflow?—This was a time when there was absolutely no rain whatever. The last rain was upon the 8th of the month, and then upon the 12th this gauging began.

7713. Were there no streams at all flowing into the sewer in the sense in which the Fleet ditch now falls into the river?—There could be no surface streams. Everything was dried up that year in July—everything was as dry as it could possibly be. I was myself observing the river Graveney, and it was absolutely dry.

7714. There are some streams which run in the driest weather, such as the Wandle. There was not anything of that kind finding its way into the leakage you allege?—Not unless by leakage. There is the Ravensbourne, which has a run of a more or less permanent character, unless there was anything of that sort which emptied itself into the sewer it is difficult to account for it.

7715. The Ravensbourne does not empty itself into the sewer?—No, but there is a sewer running up the valley which might tap it somewhere.

7716. This would be material to our inquiry in this way, that it goes to show the incapacity of the sewer?—Yes; if you have 50 gallons instead of 30 gallons per head there must be a great number of days upon which there must be an overflow.

7717. It was something that was not calculated upon?—Quite so.

7718. And this is also of importance, not so much as to the great question of collection of sewage at the outlets, but as to the inefficiency of the sewers,

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883.

causing them to discharge into the river Thames from a long way up downwards?—That is so.

7719. (*Mr. Lumley Smith.*) I believe we can test this a little further. I believe the estimate made by the Board of the sewage proper is 31¼ gallons per head?—That is so; and that agrees very accurately indeed with the average between the north and south of the actual water supply in 1881.

7720. I will ask you what you have done for the purpose of testing that, and how you compare that with the actual water discharged at Crossness. I believe you took in 1881 the water supplied by the water companies at 149,190,703 gallons per day; is that correct?—That is right.

7721. Of which the north took 99,648,892 gallons, and the south took 49,541,811 gallons?—That is correct.

7722. Then the next thing is that you have the number of houses upon the north and upon the south?—Yes.

7723. What is the number of the north?—The number of houses to which the supply was distributed was, in the north, 396,350, and in the south 204,659.

7724. From that you would get the quantity of gallons of water supplied per house, what was that?—With regard to the quantity of gallons of water supplied per house, if we divide the actual quantity supplied by the number of houses in the north it shows that there are 251·4 gallons per house supplied, and upon the south, going through the same description of calculation, there are 230·8 gallons.

7725. Then you have to get the number of persons to each house?—Yes.

7726. How do you get that?—This applies to the whole of the district supplied by the water companies, which is a much larger district than the metropolis itself, and, therefore, we have to make this fit in for the metropolis. Therefore, we took the metropolis, and we found that, in the Census of 1881, upon the north there were 8·27 persons in a house, and that in the south there were 7·09 persons in a house; so that dividing the quantity of water supplied by the respective numbers in a house upon the north and south, we get this fact, that upon the north the volume of water supplied per head of the population was 30·4 gallons, and upon the south 32·5 gallons.

7727. That agrees pretty well with the Board's estimate?—It agrees very well indeed, if you take a mere arithmetical mean, with the estimate of five cubic feet, which the Metropolitan Board of Works engineer made some years ago for the quantity of sewage per head of the population.

7728. Then you have this, that upon the south you may take 32·5 gallons per head of the population per day?—Yes. In addition to this, there will be water from other sources, but there will also be loss of water. I will do the same as Sir Joseph Bazalgette did. He estimated this additional water at from 10,000,000 to 12,000,000 gallons per day, and he strikes off that quantity as against the loss from evaporation, and so on, of the water supply itself.

7729. That gives you the amount in gallons per head. Now upon the 12th of July 1876, which I think you mentioned as being a very dry period, what do you find going off at Crossness?—That the actual quantity is 52,256,223 gallons.

7730. Does that include sewage and rainfall?—It includes everything in the sewers then; it could not include rainfall, because it had been a very dry time; there had been no rain.

7731. You take that as including sewage only?—Yes, as including sewage only.

7732. What was the population at that time?—The population at that time in the Registrar General's district was 1,113,958.

7733. How many gallons per head do you find actually flowing out upon that occasion?—46·88 gallons estimated upon the entire population of the southern half of the metropolis; but if it were estimated upon the actual population, which is smaller, it would be probably 50 gallons per head.

7734. Then although the actual water supplied by the water companies is only 30 gallons a head you find going off at Crossness 46 gallons?—We find practically 50.

7735. (*Chairman.*) How are these sewers constructed? Are they not cemented?—I do not know. I have been in them once or twice, but I have not had an opportunity of ascertaining how they are constructed.

(*Chairman.*) Do you know whether that does not admit of this explanation, that the sewers practically drain the land through which they pass.

(*Witness.*) Of course it is not necessary that this should be leakage into the Metropolitan Board of Works sewer; it might be leakage into the local district sewers; but there is the fact.

7736. (*Mr. Lumley Smith to the Witness.*) The Table, I think, you have put in shows the relative amount of sewage per head of the population, north and south?—It does. You will observe that the last Table I have put in shows the relative amount of sewage up to the latest period that we have got, calculated at per head of population. It shows that the water supply upon the north would give you rather over 30 gallons per head, and that the sewage and rainfall combined upon the north has not been very much more than the actual water supply. In some years you will see, as in 1875, that the actual volume shown flowing off at Barking is even less than the estimated volume of sewage if you take it at 31¼ gallons per head.

7737. Will you point out in what column that appears?—In the last column of the Table you will see under the head of 1875 that the total volume flowing off is only 30·8 gallons per head per day.

7738. What are you going to compare that with?—With the actual volume of sewage, five cubic feet per head or 31¼ gallons.

7739. What you mean is that the amount that actually flowed off at Barking in 1875 was below what is found to be a correct estimate of the sewage per head?—That is so.

7740. And of rainfall at Barking that year there was none that flowed off?—Although there were 29 odd inches of rainfall that year, there was not any that flowed off at Barking.

7741. There was not any more water that flowed off at Barking than would have been due to the sewage itself?—There was rather less, if anything.

7742. If you are correct in asserting that the proper estimate for the sewage is 31¼ gallons, a quantity equal to the whole amount of the rainfall of that year would appear to have got into the Thames in some other way than by the sewers without passing through Barking?—Yes.

7743. And if it passed into the Thames at all it would have passed through the storm overflows higher up the river?—Yes, if this estimate is correct.

7744. Are these quantities found to be those actually flowing off?—Those are the actual figures given to us by Sir Joseph Bazalgette as the volume flowing off.

7745. Now what do you find to be the case in 1876?—The quantity per head is a shade more, but you will observe there that though there is a little less rainfall the quantity flowing away upon the north was rather more, though upon the south it was rather less.

7746. I understand from you that the last column shows the amount per head which actually flowed off, and you say you compare that with the 31¼ gallons which you take as the normal amount of what would be sewage; but would it not have been better to have had another column showing the amount of rain which did flow off somewhere?—But that is a most difficult thing to arrive at without actual gaugings because part of the rainfall evaporates.

7747. That is sufficient for us; that allows in 1875 nothing for rainfall and in 1876 a very small margin for rainfall: could not you tell us at all what margin

the other years allow for rainfall, perhaps you could calculate that?—It is not necessary to calculate that; you see at once, if you take the difference between 31¼ and what is actually shown as the "quantity of sewage "per head per day," what quantity goes as rain. I have shown in another table the actual depth flowing off, that gives the actual depth of rainfall itself separated from the sewage, there again you have an enormous difference in quantity.

7748. I may take it again that that Table shows us what went off at Barking and Crossness and what actually fell and must have gone into the river?—Part of the difference must have gone into the river.

7749. In your judgment would the sewage of the western area have affected the discharge in the north, and how would that affect the question?—As I mentioned yesterday, it is quite clear by reading through the Reports made by the Metropolitan Board of Works to Parliament that it was intended to treat the western district separately, and that after they had got out their plans and scheme for conveying the sewage of the rest of the metropolis to Barking, and after they had half constructed the northern outfall sewer, which was only calculated for a smaller area of the metropolis, they then proposed to take the Western sewage to Barking; and of course the consequence is that by this arrangement if the sewers are assumed to be conveying their normal quantity of sewage and rainfall (that is, the quantity which they stipulated in the original calculations) whenever the sewers are conveying that amount the whole of the sewage of the western district must be flowing out a higher point, as it cannot get to any point below the Abbey Mills. The northern outfall sewers are not large enough to take it.

7750. The Abbey Mills are the last pumping station, are they not, towards Barking?—They are under the word "Stratford" on the cartoon.

7751. I do not know whether you have spoken about the capacity of the sewers not being sufficient to take the quantity, have you the figures which show that?—I have the figures here; but perhaps I had better give you the data to show how I arrive at the Western District question. I find in Sir Joseph Bazalgette's Report of the 22nd of May 1856, at page 21, that if the Western District sewage is to be taken to Barking the reservoir must hold 9,000,000 cubic feet instead of 7,000,000 cubic feet. It has been reported to contain upon one occasion 39,000,000 gallons, which is equivalent to 6,240,000 cubic feet. That is in the Metropolitan Board's Report to Parliament of the 30th of July 1864. In the Thames Mud Inquiry, at Question 6894, and Question 7034 it is given at 35,000,000 gallons. In the Report made upon the 31st of December 1873 to Parliament, at page 72 it is stated that in order to make provision for the sewage of the western district the low level sewer had to be increased in size all the way to Abbey Mills beyond what it was originally proposed to be, and that was done; it was increased from 9 ft. to 10 ft. 3 in. diameter. And then it was necessary that "the capacity of the outfall sewer and "of the Barking reservoir should be similarly aug- "mented." This was not done as reported, for in Messrs. Bidder and Hawksley's Report of the 6th of April 1858, the section of the outfall sewer for dealing with a portion of the northern Metropolis shows that there were to be two nine feet by nine feet sewers from the high level and the middle level, having a fall of two feet per mile. It shows the three outfall sewers nine feet by nine feet, having a fall of two feet per mile. Then in the Metropolitan Board of Works' Report to Parliament of the 30th July 1859, at page 7, it is stated that the northern outfall is to consist of three nine feet by nine feet sewers, and that the western area is to drain to separate outfall works at Hammersmith Creek. In the Metropolitan Board of Works' Report to Parliament of the 9th of August 1861, at page 4, it was stated that the Northern Outfall Sewer had been let for 625,000*l.*, and that the amount of work executed up to June last was 39,000*l.* In the Metropolitan Board of Works' Report to Parliament of the 31st of July 1862 (this is after the outfall had been commenced) at page 2 it is stated that it had been proposed "to "form a covered reservoir and deodorise the sewage "of the western area at Fulham Fields near the "Kensington Canal, but in consequence of a nume- "rously signed memorial having been presented, "urging the Board not to adopt that course in conse- "quence of anticipated nuisance," the Board were carefully considering the matter. In the same Report at page 3, it is stated that the value of work executed in connection with the northern outfall up to the 30th of June was 320,000*l.*, so that rather more than half the contract work had been completed. Therefore at that time half the outfall was completed, and they were still considering the matter, whether the sewage of the western district was to go to Barking. In the Report of the 31st of July 1863, on page 5, it is stated that the Board had determined to carry the sewage of the western district to Barking. At this time it is stated on page 4 of the same Report, that 615,000*l.* worth of work had been executed. Of course, that resolution may have been arrived at immediately after the former Report, but at the same time it is quite clear from these Reports to Parliament that the northern outfall sewer was not contemplated to deal with the western area, and that after it was partly completed they proposed to take the western sewage there; and they did enlarge the low level sewer, as I have already said, but not the outfall sewers.

7752. The three outfall sewers all meet, do they not?—The high level, the middle level, and the low level meet at Abbey Mills, and there are some other branches which are shown upon the plan; they come there into the northern high level to the reservoir; that is the sewer to which I am referring; it consists of three nine feet by nine sewers, and those sewers are capable of discharging 33,000 cubic feet of sewage per minute; that is rather more than Sir Joseph Bazalgette put them at in the Thames Mud Inquiry: he took them at 32,700. Then the two nine feet sewers which come into it have a capacity of discharging 22,000 cubic feet per minute, and the ten feet three low level sewer of discharging 15,000 cubic feet per minute, so that we have the three sewers up to Abbey Mills capable of discharging 37,000 cubic feet per minute, while the three sewers below are only capable of discharging 33,000, showing a deficiency equal to 36,000,000 gallons a day.

7753. It is like the neck of a bottle; if the sewers are running full when they come to the pumping station at Stratford, there would be more in them than could be pumped into the outfall?—There would be more in them than the outfall could discharge, therefore it must overflow at a higher point.

7754. How often they do overflow you are not going into?—I am only dealing with the capacity of the sewers, and using the same formula for calculating their discharging capacity as was used in some of the early Metropolitan Board of Works' Reports.

7755. Have you the capacity of the discharge at the outfall at Barking?—The discharge at the outfall at Barking is 33,000 cubic feet a minute, while the sewers would bring down to Abbey Mills 37,000 cubic feet a minute.

7756. Upon the south have you corresponding figures?—Upon the south the sewer is capable of discharging 20,000 cubic feet a minute.

7757. And the outfall?—There is but one sewer there. I have dealt with this separately in this way, that if we take the ordinary sewage which is shown by the gaugings to be upon the south eight cubic feet per head of the population, during the nine hours of maximum flow instead of six, we have got 8,955·5 cubic feet per minute of sewage, to which if we add a quarter of an inch of rain flowing off 20 miles, and one-eighth of an inch flowing off another 20 miles, they equal together 12,075 cubic feet, and the rain and sewage together are equal to 21,660·5 cubic feet; so that as the sewer is only capable of discharging 20,000 cubic feet there is a deficiency there of about

*Mr. B. Latham, M. Inst. C.E.*

24 Jan. 1883.

15,000,000 gallons a day. We have got these figures more accurately for the south having got the gaugings for one day for the south and none for the north, but I have taken the northern outfall, and if you take the figures which have been given to us of the volume of rainfall as 28,500,000 cubic feet per day (the quantity stated in the Report of Messrs. Bidder, Hawksley, and Bazalgette, and also as stated in the Report to Parliament) that is equal to 19,791·7 cubic feet per minute. Now, if you take the estimate of the Metropolitan Board of Works' engineer of five cubic feet per head of sewage, half flowing off in six hours, from 2,353,900 persons (their estimate of the population at the time) it gives 16,346·5 cubic feet per minute; and those two figures added together are equal to 36,138 cubic feet a minute; showing that according to their own population this northern outfall sewer never could have carried the quantity for which it was designed.

7758. (*Professor Williamson.*) Are you taking half the five cubic feet as being discharged in all places simultaneously in six hours, or do you make allowance for the difference of distance that the quantity would have to travel?—No; upon the north we know nothing about the figures. Upon the south I am able to tell when it flows off. But as regards the sewers, on the north, taking their own figures of the volume of rain as admitted, and the volume of sewage from the population as that which they give, it shows that they never could have been adequate to the maximum by the difference between 33,000 cubic feet and 36,158 cubic feet. But if we add to that the population which we know exists outside and the rainfall from the outside, a very much larger deficiency arises. You will see that in the case of the outside district, whatever rain falls must go into the sewers, and must first occupy them, as they occupy the highest position, to the exclusion of any other water which comes into the Metropolis; for until part of that can flow away by the storm overflow it must still occupy the sewer to the exclusion of whatever comes in from the Metropolis itself.

7759. (*Chairman.*) The sewers will carry off the sewage without rain water, they are sufficient for that?—Yes, they are sufficient for that.

7760. It was contemplated that there would be sometimes storms of such excess that they would not carry the water off?—Yes, it was contemplated that might happen.

7761. But in certain rainfalls they would?—Yes.

7762. Can you tell us what proportion or quantity of rainfall they calculated they could carry off so as to show us how many days there would be an overflowing of storm water?—They have already shown us that if the rain happened to come when there was the maximum period of flow they would only carry away one-hundredth of an inch per hour.

7763. But does it at all appear upon how many days they calculated that there would be a greater flow than that?—The evidence which they give in this report would lead you to believe that it only occurred upon 12½ days, for they say that although the sewers will carry a quarter of an inch that quarter of an inch is produced by four-tenths of an inch of rainfall, and they state that that rainfall only occurs upon 12½ days of the year. But that is an entirely erroneous assumption, because you have to do with the rate at which the rain falls, and not with the quantity falling in the day. I have had observations taken at Croydon by means of a registering and recording rain gauge, by which every drop of rain which falls, and the rate at which it falls, is recorded; and I have an apparatus showing to what extent the sewers are affected by these rainfalls, but at Croydon the conditions are more favourable, and the sewers do not show such great fluctuations in flow as in London, for this reason, that a large portion of the surface water is not admitted into the sewers, it is only that portion falling upon the roofs of the houses that we deal with. But I shall be able to show you from these observations which I have made that it seldom rains, but the sewers must be affected to a greater extent than for which provision is made.

7764. (*Mr. Lumley Smith.*) I think you have a reference to one report of Sir Joseph Bazalgette upon the subject in 1853?—Yes, I find that Sir Joseph Bazalgette, when the great London Drainage Bill was before Parliament, made a report and gave evidence upon the question. I find that that Company proposed to admit a quarter of an inch of rainfall, whereupon he gave evidence to the effect that if they admitted no more rainfall than that the sewers must still overflow into the river all the way along, on from 80 to 100 days in the year.

7765. (*Chairman.*) Did Sir Joseph Bazalgette say so?—Yes; I will find you the reference to it. I have here the evidence which was given before the Select Committee of the House of Commons upon the great London Drainage Bill, on the 10th of June 1853, and you will observe the passage of Sir Joseph Bazalgette's evidence, which is within pencil marks — it is at Question No. 2558.

*The passage referred to was as follows:—*

"*Q.* Assume that a hundredth part of an inch of "rain per hour falls in addition to the maximum flow "of sewage passing into the sewers what would that "give?—*A.* For 47½ square miles it would give "19,132 cubic feet per minute, which added to "12,638 cubic feet of sewage, would give 31,770 "cubic feet per minute. The quantity that the sewer "would carry off may be taken at what the pro-"moters' engineers put it at. The sewer would be "too small for that quantity; I do not say that that "is the quantity to be carried off, it is a question of "degree. Thus, the more you can carry off the less "frequently will the sewage go into the river; the "less you carry off the more frequently. I think if "it were capable of carrying off that quantity, still "from 80 to 100 days the sewage mixing with the "rainfall would go into the river. The average of "the last four years give 150 days per annum on "which rain falls."

Adjourned to Tuesday next at half-past twelve.

# SEVENTEENTH DAY.

## Tuesday, 30th January 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
WILLIAM POLE, Esq., F.R.S., *Secretary*.

30 Jan. 1883.

(*Mr. Lumley Smith.*) Will you allow me to observe before going on with the evidence that there was handed in upon the last occasion a series of tables which had been prepared by Mr. Mansergh, whom I am going to call, which showed the effect of the mixing action upon the river Thames. It showed the various points along the river from Teddington to Southend, the actual area of the cross section and the relative portions occupied by sea water, and water that was otherwise than sea water; and, upon those calculations which had been prepared by Mr. Mansergh, Mr. Latham had formed certain calculations, and Mr. Mansergh, with the view to his examination, has been engaged in checking the areas derived from the cross sections, and he finds that with regard to one cross section there has been an error of calculation; that a figure has slipped out,—a figure which was 242 was carried out as 42,—the result is that there ought to be an addition to the sectional area at Crossness of 6,400 feet. In consequence of that I have had amended tables prepared, and the figures which are affected are the figures upon the line at Crossness. Those amended figures will have to be given.

(*Chairman.*) That removes a difficulty that I pointed out, does it not?

(*Mr. Lumley Smith.*) It does remove the difficulty of there being apparently less sewage at low water at Crossness than there was at Barking, although there was, as my learned friend pointed out, an additional outfall. But it still appears that at high water at Crossness there is very little less sewage in the water than at Barking, but that probably will be owing to the high water having pushed up the more diluted water from the sea.

MR. BALDWIN LATHAM, Mem. Inst. C.E., called in, and further examined.

*Mr. B. Latham, M. Inst. C.E.*

7766. (*Mr. Lumley Smith.*) We left off upon the last occasion when some questions had been asked by my Lord as to the number of days on which the rainfall would probably exceed the amount originally provided for; I think you gave us the passage from Sir Joseph Bazalgette's evidence which now is printed upon the notes of the last day's evidence, which shows that on from 80 to 100 days the sewage mixing with the rainfall would go into the river?—That is so.

7767. Have you referred to any other extracts from reports which bear at all upon that subject, which you could conveniently give us?—There are other passages in the same evidence.

7768. If there are any other passages to which you think it is important that attention should be drawn, perhaps you will mention them?—Question 2536 in the evidence given upon the London Drainage Bill on the 10th of June 1853 was, "For how many "days, as you compute, would the sewage continue "to flow into the Thames as at present?" And the answer was, "I think that something near 100 days "in a year the sewage would continue to flow into "the Thames." Then there is a report of the 7th of May 1853 to the Commissioners of Sewers by Sir Joseph Bazalgette and Colonel Hayward to this effect, "There must still be from 80 to 100 days when a por- "tion of the sewage mixed with the rainfall must in "quantities more or less go into the river as at "present." And to show that this London drainage scheme contemplated taking a quarter of an inch into the sewers, the engineer for the scheme, Mr. Mitchell, at question 520 refers to the quarter of an inch of rainfall, and states that it does not occur on more than 23 or 24 days in the year; that was the quantity which they proposed to admit into the sewers. Then at 521, he was asked, "You provide for all but those "23 or 24 days upon which more than a quarter of "an inch falls," and his answer was, "Yes."

7769. Those are all passages from the evidence given upon the same inquiry?—Upon the same inquiry.

7770. That is to say, given before the Select Committee of the House of Commons on the London Drainage Bill, on the 10th of June 1853?—The last one I quoted was from the evidence given upon the 6th of June 1853.

7771. Are there any other passages to which you wish to draw attention before I pass on?—Not with regard to the quarter of an inch.

7772. I believe you yourself have, for a considerable period, been conducting experiments at Croydon with regard to the rainfall?—Yes.

7773. And as to the way in which that affects the sewers?—Yes.

7774. (*Chairman.*) I should like to ask this question—the statement quoted from Sir Joseph Bazalgette's evidence is, "Still, from 80 to 100 days the "sewage mixing with the rainfall would go into the "river;" that does not, of course, mean the whole of it?—No.

7775. It might be 5 per cent. of the mixture of rainfall and sewage?—It all depends upon the rate at which the rain has been falling. The sewers were calculated or supposed to take 100th of an inch of rain an hour. But your Lordship will observe, from what I have already stated, that in the higher parts of the district the sewers were not calculated to take 100th of an inch an hour, but only half of it; so that whenever it rained at such a rate that the water would enter the sewers at a greater rate than the 100th of an inch an hour, and at the same time there was the maximum flow of sewage passing, that would cause the sewers to overflow.

7776. I am not saying that 100th of an inch might not be an objectionable thing, but it might not be more than one per cent. of the volume of sewage?—The overflow might not exceed that, or it might exceed it many times.

(*Chairman.*) All I mean is that this quotation from the evidence is very vague and uncertain, as you cannot tell what quantity would go.

(*Mr. Lumley Smith.*) It cannot, of course, be more than a matter of general supposition.

7777. (*Chairman.*) Suppose the 100th of an inch in an hour, and the sewage at its maximum rate, can you tell what percentage of what we may call the mixture would overflow?—I think I have already given the figures to show what the 100th of an inch

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

produces in an hour, and what the ordinary sewage is, showing that the rainfall is very much in excess of the sewage itself.

7778. We have it that "for 47½ square miles it "would give 19,132 cubic feet per minute, which, "added to 12,638 cubic feet of sewage, would give "31,770 cubic feet per minute. The quantity that "the sewer would carry off may be taken at what the "promoters' engineers put it at;" what is it that these sewers would carry off?—That I have not worked out. What was then proposed was a different fall altogether from that of any of the present sewers.

(*Mr. Lumley Smith.*) Your Lordship sees that many of the storm overflows are self-acting, and that what passes through them in the course of a storm is not measured; so that it is only by calculations or estimates of this kind that you can get any idea of what quantity does go into the river other than through Crossness and Barking.

(*Chairman.*) Say, sewage 12 and rainfall 19, making 31; if the capacity of the sewer were 32, about 3 per cent. of the total quantity would be overflow, and of that 3 per cent. nearly 2 per cent. would be rainwater and 1 per cent. would be sewage. I do not mean to say that that would not be a serious amount, but it would be diluted.

(*Mr. Lumley Smith.*) No doubt.

(*Mr. Bidder.*) Your Lordship sees that what another gentleman says would be the consequence of the adoption of another scheme, which never was adopted, is very remote from the question before you.

(*Chairman.*) I understand Mr. Latham to say that what Sir Joseph Bazalgette said he said truly.

(*Mr. Bidder.*) But what Sir Joseph Bazalgette said upon that occasion was with regard to a certain Bill then before Parliament, which was of a radically different character from anything that now exists, and it is rather a hasty assumption to assume against Sir Joseph Bazalgette that, because he said certain consequences would arise if certain works were carried out, therefore he inferred that the same consequences would arise if entirely different works were carried out. The quantity of overflow depended upon the capacity of the streams to carry off the quantity of water; the quantities or capacities of the two streams are enormously different.

(*Chairman.*) You surmise that the sewers are of a greater capacity than the suggested sewers which this evidence referred to.

(*Mr. Bidder.*) About two and a half times as great.

(*Chairman.*) If that is so, that makes the evidence not of much value certainly.

(*Witness.*) I am afraid that is not so; there is evidence given before the Committee as to the discharging capacity of the proposed sewers, and you will observe that the area drained is very much smaller than that now actually drained in the Metropolis; but I would draw attention to this fact in this former evidence that this is a quarter of an inch of rainfall proposed to be admitted in addition to the ordinary sewage, and it is exactly the same amount as is now stated to be admitted, but in fact was really more; because in some parts at the present time an eighth of an inch is admitted, and it was pointed out that in that time the overflow would be from 80 to 100 days with a quarter of an inch, whereas now the overflow is put at from 14 to 30 days with less than a quarter of an inch.

7779. (*Chairman.*) Mr. Bidder's objection is this; he said Sir Joseph Bazalgette took this to be true, and no doubt it was true, but how is that relevant when the sewers in actual existence are two and a half times the carrying and discharging capacity of the sewers of which he was speaking. Do you agree that the sewers now are of a greater capacity than the contemplated sewers they were speaking of?—No, I do not. I think I can find out what the discharging capacity of these sewers was proposed to be, they proposed to deal with a hypothetical future population just as the present sewers did; and yet it is said, with regard to the existing sewers, that they can only overflow from 14 to 30 days, whereas of the former sewers it was said that they would overflow from 80 to 100 days.

(*Chairman.*) Have the present sewers a greater carrying and discharging capacity than the sewers then contemplated?

(*Witness.*) Not with regard to the area.

(*Mr. Lumley Smith.*) Having regard to the area and the population, do you think there are such distinctions between the scheme then proposed and the scheme now in use as to make that calculation erroneous?

(*Mr. Bidder.*) I may help you in answering that question. I am told that the sewerage scheme upon the north side of the Thames proposed one sewer 10 feet 3 inches diameter, whereas the existing scheme contains three sewers of 9 feet diameter each.

(*Witness.*) But you must bear this in mind that the sewers are just four feet a mile fall, instead of two feet a mile fall, whatever their size was.

(*Mr. Lumley Smith.*) I do not know whether you have gone sufficiently into the details of that scheme to be able to compare the respective areas drained, and the two populations.

(*Chairman.*) I suppose the witness will admit that the discharging capacity of the actual sewer is very much greater than that of the sewer then contemplated.

(*Mr. Bidder.*) Very much greater.

(*Witness.*) The answer to question 538 of the engineer's evidence of the 6th of June 1853 shows that the discharging capacity of the sewer was 20,000 feet a minute.

7780. (*Chairman.*) And what do you say is the discharging capacity of the existing ones?—The discharging capacity of the three existing ones is 33,000 cubic feet a minute.

7781. (*Mr. Bidder.*) Do you mean upon the north side?—Yes.

(*Mr. Bidder.*) I will give you what Sir Joseph Bazalgette gives to me. The discharging capacity of Mr. Mitchell's north side 19,000, and of the existing north side 33,000; south side discharging capacity, Mr. Mitchell 5,300, and the capacity of the sewer as now constructed 19,000, making the two sides together 24,000 as proposed, and 52,000 as constructed; therefore, I was speaking roundly of the two together; I ought to have said, if you take them separately, north side not quite double, and south side rather more than three times.

7782. (*Chairman.*) I think we must take each side separately. I do not know whether you will agree to those figures of 19,000 and 33,000?—I have already given the discharging capacity of the northern outfall as 33,000, as against 32,700 given by Sir Joseph Bazalgette the Mud Inquiry.

7783. Do you agree that this former proposition gave a discharging capacity of 19,000?—No, it gave 20,000; and, moreover, it was only dealing with the low level district and the low level sewer; and it was afterwards stated in evidence that when the population increased a high level sewer would be put in.

(*Mr. Bidder.*) But Mr. Mitchell stated that he was going to deal with 47 miles upon the north side.

(*Chairman.*) This is a matter upon which there can be no real difference between Sir Joseph Bazalgette and the witness, because it seems to be a matter of abstract calculation.

7784. (*Mr. Lumley Smith to the witness.*) You proceeded upon the same plan as Sir Joseph Bazalgette, I think, by taking the average rain of the day at per hour?—Yes.

7785. And you have also adopted the same plan of taking the discharge from the number of square miles?—Yes; I read the passage upon the last occasion, showing that it was 47½ miles; but it was stated in the Metropolitan Board of Works Report that the drainage area is 59 miles at the present time.

7786. (*Chairman.*) Taking the carrying and discharging capacity of the sewers to be what they now are, what would be the number of days upon which

there would be an overflow according to your calculation?—I am going to give you that from direct observations.

7787. (*Mr. Lumley Smith.*) Will you tell us the number of observations which you have made upon which you base your resulting opinion?—For some years I have thought it very important that engineers should know more about the rate at which rain falls, and I have designed a registering rain-gauge, which has now been at work at my house at Croydon since the beginning of 1879. That records the time of day, the quantity and the rate at which rain falls. Then, while I was making these observations, I was gauging the Croydon sewers, not to see the quantity of the rain or how that affected them, but simply because there was a leakage into the Croydon sewers of spring water. I was desirous of ascertaining what was the quantity of the leakage, as the object of my experiments was to ascertain the amount of water which the chalk formation in that neighbourhood yielded; but in making those experiments I have been obliged to deduct every day the quantity of sewage proper; and, knowing also the rate of fluctuation at every moment of the day, I am able to show how much any particular fall of rain affects the fluctuation in the Croydon sewers. But I should say that with regard to Croydon it will not compare with London, for this reason, that a very large amount of the rainfall at Croydon is excluded from the sewers; that is, that there is a separate system for taking the rain from the streets, and it is only the rain from the roofs of the houses which could not be excluded from the sewers, and that which finds its way into the sewers. In districts where the rainfall from the whole district is admitted into the sewers it would cause a very much greater rate of fluctuation. At Croydon the way in which it has been done is by affixing upon the outfall sewer a recording machine which is actuated by a float. These are the diagrams (*shewing some diagrams*) which show the quantity in cube feet per minute every hour of the day, and I have here a continuous record of the total quantity at every hour of the day, and the average and the actual quantity of the sewage flowing every day (*producing the same, see Appendix* A. C.)

7788. (*Mr. Bidder.*) Will you just explain how that bears upon this inquiry?—I am just pointing out in a district like this the mode in which the observations have been made, so as to show how much rain in this particular district affects the sewers at the particular period when the rain occurs.

(*Chairman.*) Could you tell us what the result of your experiments was?

7789. (*Mr. Lumley Smith.*) As I understand, you had an opportunity of gauging the quantity of sewage that passed out at Croydon?—Yes.

7790. And you also had an opportunity of accurately gauging the amount of rain that fell?—Yes.

7791. And you were enabled to compare those observations, and so far form an opinion how far the rainfall affects the discharge from the sewers?—Yes.

7792. In comparing Croydon and London, are there certain corrections to be made, because in Croydon there is more rainfall diverted from the sewers than in London?—That is so.

7793. Bearing in mind these distinctions, will you tell us the conclusion you come to with regard to the sewers?—I must also make another observation with regard to the rainfall and the sewers, and that is, that the degree of fluctuation caused by rain depends upon the time of day when the rain falls. If it should happen that the rain occurs when the minimum quantity of sewage is flowing through the sewer, it will not affect the mean quantity to the same extent as it would if it occurred at the period when the maximum quantity was flowing through the sewer.

7794. (*Sir John Coode.*) When you say it will not affect the mean, you mean it will not affect the gorging or the overflow?—I am going to show the ratio of increase in the sewers by particular rains. At some periods you would get a very small increase beyond the normal flow; at other times you would get it considerably greater, owing to the fluctuation of the sewage itself; but by taking a very large number of observations, extending over a number of years, you may expect to arrive at a reasonably fair conclusion. In this case I have 573 distinct observations, every one of them made on a separate day, and every one of them made within a certain single hour, and they show that during that period there were 152 days in the average of the last three years and nine months when rain at the rate recorded in those tables fell; that is to say, there were 152 days in a year on the average on which ·065 of an inch fell in an hour. That is the average of the single hour carried over the 573 days, and showing the rate at which rain fell.

7795. (*Mr. Bidder.*) Irrespective of the duration of the time during which rain fell at that rate?—I have here the times at which it fell. I have the quantity which fell in the day, and the quantity in the hour, the time in which that fell, the rate of fall in 24 hours, and the time of day at which it fell, and the proportion of the flow of sewage to the mean fall caused by the particular rainfall.

7796. Will you tell us on how many days the quarter of an inch fell?—I have already pointed out that there were 152 days in a year upon which an average of $\frac{6}{100}$ths of an inch fell in the hour.

7797. (*Mr. Lumley Smith.*) We have to consider, have we not, whether that all fell in a few minutes or in an hour?—Yes.

7798. Does your table show the duration of time in which that fell?—It does.

7799. (*Chairman.*) So far as it relates to the actual fall of rain, would Croydon be a fair parallel to London?—There would be little or no difference.

7800. (*Mr. Bidder.*) Subject to one very important observation, that in Croydon you are dealing with the observation of a particular spot, and discussing the area these sewers have got to do with as compared with an area of over 100 miles, you cannot argue from what you get at a particular spot to what you get over 100 square miles.

(*Chairman.*) Not if you take 573 observations?

(*Mr. Bidder.*) No, because we are dealing with what may be called sharp showers, which are, as we know, very local.

(*Chairman.*) But the extraordinary falls are no more likely to happen in Croydon than at any other place.

(*Mr. Bidder.*) No, I agree to that. But the question is whether the main intercepting sewers can deal with a similar rainfall in a certain time over any part of the whole area of the Metropolis. Assuming that these observations represent not only the number of showers you might expect at Croydon, but at any particular spot of the Metropolis, you must not infer that you would get that number of showers of that violence over the whole of the Metropolis. It may be perfectly fine at Norwood, for example, but there may be a smart shower at Hampstead.

(*Chairman.*) The witness gives you the benefit of that by taking a fine day at Croydon when it may have been fine at Hampstead.

(*Mr. Bidder.*) No, the witness says there is a fine day at Hampstead when at Croydon rain falls which would overtask the sewers; now assume that as a fair sample of what happens in the Metropolis; then, if you had your rain gauge at Hampstead or anywhere else, you would get that same result; but when you are discussing whether upon 152 days you will have that quantity of rain falling over part of the area, you must bear in mind that the 152 showers at Croydon will not happen at the same time as 152 showers at Westminster, for example.

(*Chairman.*) Let us see how you address yourself to Mr. Bidder's objection.

(*Sir John Coode.*) I thought Mr. Bidder's argument was that, although you may have that particular rainfall at a particular spot at Croydon, you will not find a rainfall to the same extent over the area drained by the Metropolitan system.

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

(*Mr. Bidder.*) That is so.

(*Mr. Lumley Smith.*) Then the deduction that the witness draws is this, that, as this particular fall at Hampstead may be carried away by all the sewers in the Metropolis, they being united and able to take it off, yet in reality the overflow goes into the sewers at that particular point.

(*Mr. Bidder.*) Suppose there was a smart thundershower at Hampstead which was so much beyond the capacity of the Hampstead sewers that it ran down the gutters of the roads; before it can get to the Thames it must have overtasked the intercepting main sewer.

(*Mr. Michael.*) Three of them.

(*Witness.*) I can only tell you this, that I have a very much larger area under investigation for rainfall than the Metropolis. I have rain gauges all through the county of Surrey, and it is very rarely, when the rain does occur, that it does not occur generally throughout the district. There are of course exceptions, but principally in summer time, and those are the times when there are certainly local thunderstorms.

7801. (*Mr. Lumley Smith.*) Do your observations distinguish at all between what are local thunderstorms and what are merely increased quantities of rain falling on rainy days?—We could show, because we mark them, what is due to thunderstorms, but we have not had so many thunderstorms of recent years as occurred formerly.

7802. But the result, as you told us, is this, that the number of days upon which a given quantity of rain falls in an hour exceeds that which was calculated for in the metropolitan drainage scheme?—Yes. Now I was going to explain that in the nine months of 1879 (taking the average of all the observations upon the days upon which rain fell) there were 133 days upon which rain fell, and the average of all those in one hour was ·066; and I find that on the average that increased the mean flow in the Croydon sewer by 4·9 times. In 1880 there were 135 days in the whole year when rain fell at the rate, upon the average of one hour, of ·075. Now that was the driest year with regard to the number of days, and yet it had the greatest rate of rain; the rainfall was 30 inches in that year, as recorded at the site where the registering rain gauge was located. That increased the flow in the sewers 3·78 times; it was a much drier year on the whole, for 1879 was a notoriously wet year.

7803. (*Chairman.*) You say it increases the flow by 3·78 times?—Yes, its mean flow.

7804. That is during the time the rain was lasting?—If you refer to the particular hour, which is shown in the column at which that particular rain affected the sewers, you will find that on an average of all the experiments, the increase was 3·78 times the mean flow in the sewers.

7805. That made it about four times as much as it was before?—Yes, that is so.

7806. Was the rain that fell four times the quantity of the sewage?—It may have been more than that.

7807. But according to your gauge?—If it continued at that rate during the whole 24 hours, it would have been.

7808. Then we do not understand that it continued at the same rate all the 24 hours?—No, only during that hour.

7809. (*Mr. Bidder.*) Then comes the question, How far is the Croydon sewage neat sewage as compared with London sewage, which is very diluted. But the Croydon sewage, as I understand, is very much less adulterated with water?—It is quite the reverse; the quantity of water supplied at Croydon is 50 gallons a head, and therefore the quantity of sewage is much greater per head of the population.

7810. (*Chairman.*) But you said a good deal of the storm water ran away and was not mixed with the sewage?—Part of the rain water itself is not carried into the sewers, being carried into a separate system, but still this is the result with this separate system, showing with these separate systems how the quantity that gets in affects the mean flow. There is more sewage per head of the population in dry weather in Croydon than there is upon the north side of London. Upon the south side, as I have already pointed out, it is about the same as at Croydon, but in addition to that there is a large amount of leakage into the Croydon sewers, which greatly increases it again; and it was my object in making these observations to ascertain the extent of that leakage. Then, in 1881, there were 144 days when the falls were observed, and the average of those was ·06 per hour, and the increase in the flow of the sewers of that year was 4·27 times the mean flow. In 1882 there were 161 days when the falls were observed to affect the sewers, and the average rate of fall in all those days was ·06, and the increase of the sewers during that period was 3·7 times the mean flow. There is no doubt that, owing to the leaky character of the sewers at Croydon, when rain does fall, some of it does run out into the subsoil, as during the dry years of 1880 and 1882; that is to say, we have had lower springs in those two years than we have had at other periods; we do not get all the rain that gets in measured, because the leaky sewers act as overflows. The average shows that of all those periods of the 573 observations upon the sewers the mean rate of flow is increased 4·16 times.

7811. (*Mr. Lumley Smith.*) By what quantity of rain?—By ·065.

7812. (*Chairman.*) Are the sewers capable of carrying off that quantity at Croydon?—Yes, there are no overflows whatever except those by percolation into the ground.

7813. Then is the inference that, if the London sewage had been increased at the same rate, there would have been an overflow?—There must have been an overflow all this time; but, the London sewers admitting more rainfall than we do, the ratio must have been greater.

7814. Is it the fact that in London the sewers admit a larger proportion of the rainfall than at Croydon?—Certainly, in London the sewers admit all the rainfall, whereas at Croydon they only admit that which falls upon the roofs of the houses.

7815. (*Chairman.*) Is it the fact that at Croydon the sewers would carry off five or six times the volume of sewage which they habitually have?—They would carry more than that. There are times that the rainfall has exceeded 12 times the mean flow, and they have carried it off; and I have made observations upon days upon which a quarter of an inch and less has fallen, which shows the enormous ratio which takes place sometimes. For example, upon the 20th April 1879, a quarter of an inch of rain fell in 24 hours. In one hour of that day the rain caused the flow in the sewer to fluctuate in the ratio of 7·1 times its mean flow. Then again, upon the 25th of June, when there was only ·135 of rain, that caused an increase of seven times the mean flow in the sewers. Then again, upon the 13th of September with a quarter of an inch of rainfall, there was an increase in the mean flow of 6·3 times. In 1880 there was not such a great rate of fluctuation, but upon the 8th February, with ·14 of an inch of rain, the ratio was 5·2.

7816. (*Chairman.*) Let me ask you a question to see if I understand this. Of course you know the volume of the discharge of the sewage?—Yes.

7817. You calculate the area over which the rain fell. You can calculate it in a sense, but not altogether, as you cannot make an accurate deduction for roads and gardens?—It is almost impossible. The total drainage area draining to these sewers is about 1,990 acres, but how much of that has rain falling off it, it is almost impossible to tell with any degree of accuracy. Then I was going to show that in 1881 upon the 6th of July ·16 of an inch fell in 24 hours, which increased the flow in the sewers by 7·2 times the mean flow; and upon the 2nd of October of this year, when ·21 of an inch fell in the day, it increased the flow in the sewers 8·3 times the mean flow. I have a large number of observations which show that there are occasions when a very much smaller quantity

than a quarter of an inch of rain in 24 hours increases the mean flow in the sewers eight times.

7818. (*Sir John Coode.*) Have you made any observations to show how often in the year the Metropolitan sewers overflow into the Thames?—I have no information upon that point.

(*Mr. Bidder.*) We shall be able to give the Commission at the proper time some actual facts, at any rate, as to one of the principal ones.

7819. (*Chairman to the witness.*) Your evidence will go to show how many times they ought to overflow, so to speak?—My evidence is to show that, with the certain rates at which rain falls, and the certain rates at which it flows off, as shown by the fluctuations of the sewer at Croydon, under any circumstances any set of sewers must be affected in some degree by these conditions.

7820. You invite the inference that the augmentation of what went through the sewers in London would be the same as you have found in Croydon?—At least.

7821. And that therefore it ought to or would overflow on so many occasions; but I suppose they know upon the side of the Metropolitan Board of Works what the actual number was, do they not?——

(*Mr. Bidder.*) I know in one of the principal cases that it is a very different number from what the witness has suggested.

(*Mr. Lumley Smith.*) In the general sketch that was given by Sir Joseph Bazalgette at the beginning of this inquiry he gave it as a matter of estimate that probably upon some 14 days in the year there would be an overflow.

(*Sir John Coode.*) Sir Joseph Bazalgette said from 14 to 21 days, and in a very wet season he said 30 days.

(*Mr. Bidder.*) In many cases it is practically impossible to have observations, but in one case, if not more, we have the actual records and shall be able to give you the facts extending over several years. I shall be able to give you the facts extending over seven or eight years, but I cannot pretend that I shall be able to give them to you extending over all the outfalls.

(*Sir John Coode.*) About what proportion of the whole number shall you be able to give evidence?

(*Mr. Bidder.*) I can hardly tell you at present. Probably it has occurred to the Commissioners that, before inferring from Croydon, or from any place to London, there are ever so many elements to be taken into consideration, not merely the rainfall; because, for instance, the amount by which the volume in the sewer is increased by a certain rainfall depends upon the relative proportion of the area contributing rain to the sewer to the population whose sewage is in the sewer.

(*Chairman.*) I think it can only be called what is known as approximate evidence.

(*Mr. Bidder.*) I venture to think it is not even that.

(*Mr. Lumley Smith.*) Dealing with a case in which it is said that it is impossible to have any accurate observations, we must take what we can get.

(*Mr. Bidder.*) Suppose that Croydon, for example, were a place in which there were only three houses and 20 people, and the rainfall of a square mile got into the sewer; the difference between the sewage and the tenth of an inch of rain would be enormous; but supposing you have 20,000 people upon that area, you have just the same amount of rain falling, and a thousand times the quantity of sewage.

7822. (*Sir John Coode.*) No doubt; and there is also the question of the soil, whether it is retentive, or otherwise. What is Croydon?—Some parts chalk and some parts gravel, other parts London clay, and other parts the Woolwich and Reading beds.

7823. (*Chairman.*) We might ask you what is the population of Croydon compared with the area over which it is spread; it is not so dense as in London?—Nothing like it. The population of that part to which I am referring is something over 60,000; it is about three square miles, and there are 60,000 people upon it, making 20,000 to the square mile.

(*Sir John Coode.*) If the Metropolitan Board of Works can give us observations over a considerable portion of their sewers, extending over a considerable period of years, we had far better deal with the facts, if the facts are sufficient to form a conclusion upon.

(*Mr. Lumley Smith.*) From Sir Joseph Bazalgette's evidence I inferred that they were not in a position to give us those facts from these overflows being self-acting.

(*Sir John Coode.*) If they can do it, then all this is wasting time, I imagine. If they cannot, then this evidence is valuable.

(*Chairman.*) Suppose the Metropolitan Board of Works can give us statistics or figures upon this matter, Mr. Latham will have an opportunity of seeing them. If he says these figures require explanation or do not give you the whole truth, he will have an opportunity of coming before us again and telling us that.

7824. (*Mr. Lumley Smith to the witness.*) Then, without going more into detail, I will ask you the general question; what is the inference which you draw as to the London sewers from your observations at Croydon; is it summed up by what you have told us, that the number of overflows in London would be more than has been estimated in the evidence which has been given?—I say so, most decidedly.

7825. Could you form any opinion as to the number of times in a year when overflows would probably happen?—The only part of the Metropolis that we really know anything about with regard to the volume of the sewage is upon the south side; and there I think the ratio of the flow in time of rain to the mean flow is shown to be about 3 to 1; the exact quantity is 2·76 to 1.

7826. (*Chairman.*) That is to say, that if the rain were about double the sewage it would fill the sewer?—It would.

7827. And you say it would be often more?—My observations enable me to say so from this district, which bears a very fair comparison to the south side of London.

7828. Taking that district, how often would the sewers be incapable upon the south side?—Upon the average, every time rain occurred the sewers must overflow in the case of London.

7829. Whenever it rained?—Whenever it rained, at some point or other they must overflow.

7830. (*Mr. Lumley Smith.*) Now I pass on to a matter connected with the actual reservoirs that are at present employed. You were asked a question upon a previous occasion as to the capacity of the reservoirs?—I was asked whether the reservoirs were of sufficient capacity to deal with the dry-weather sewage. I answered, yes; but I had in my mind that we were only dealing with the south of the Thames, and dealing with the quantity which it was originally calculated by the board's engineer would have to come down; they are not competent to deal with the quantity which actually comes down.

7831. That is to say, upon the south side?—Upon the south side.

7832. That is to say, that in the twelve hours of tide they do more than fill?—Yes, the tidal period is 12½ hours. We may take it for the purpose of calculation. Now originally, from the report of Messrs. Bidder, Hawksley, and Bazalgette, of the 6th of April 1858, those were to discharge for 2½ hours. Of course they must therefore hold 10 hours' sewage. There being 1,200,000 people upon the south side, representing about 10,000,000 cubic feet of sewage per day, and assuming that half the total sewage flows off in nine hours, which is the rate it is now shown to be flowing off at, it is quite clear that a reservoir which only holds 4,000,000 cubic feet cannot hold 10 hours' sewage; but if, as appears to have been already given in evidence before you by Sir Joseph Bazalgette, you increase the time of discharge and limit the period of storage, you can make the reservoir hold anything

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

you like; in fact, in this case you see the reservoirs have been made to hold eight hours' storage only.

(*Mr. Bidder.*) May I be allowed to suggest whether it is worth while to waste time about this, when Sir Joseph Bazalgette has said that the Metropolitan Board of Works are only awaiting the result of this inquiry to enlarge the reservoirs. They have come to the conclusion that the reservoirs are not large enough, and are only waiting for an opportunity to enlarge them. It is conceded by both sides.

(*Witness.*) I am referring to questions 57 and 58 on page 8 of the evidence given before the Commission, and question 145 on page 14. You will there see that the time of discharging upon the ebb is increased to four hours, and the time of the storing is eight hours. Of course the result of that is that the sewage must come very much further up the river if it is discharged for four hours, instead of two-and-a-half hours as originally contemplated.

7833. (*Mr. Lumley Smith.*) What is the conclusion you have come to?—The conclusion I have come to is that on both sides of the river the reservoirs are very much too small, but immeasureably so upon the north side; because, as you will observe, the reservoir upon the south was to accommodate 1,094,600 people according to the original estimate, and to hold 4,000,000 cubic feet. Assuming that the reservoir upon the north holds 39,000,000 gallons, which is one of the estimates (35,000,000 is given in this inquiry), it will only accommodate at the same rate at which the south provides 1,707,576 people; whereas the actual population upon the north is very much greater than that; and this 1,707,576 is very much less than the population which it was originally estimated had to be dealt with upon the north; but that is no doubt due to the fact of their having brought the western sewage there without having enlarged the reservoir. If the reservoir upon the north side had been made to hold the 9,000,000 cubic feet which it was reported by Sir Joseph Bazalgette it must hold if they brought the western district sewage there, it would have accommodated the population which was estimated; but, seeing that it was not enlarged, it would only accommodate a very much smaller population in the proportion that the south was provided for.

7834. (*Mr. Lumley Smith.*) Then all the sewage which cannot be provided for must be let into the river at one place or another, regardless of the tide?—Yes; upon the north, as I have pointed out, the reservoir, if it held 39,000,000 gallons, would only hold the sewage which the three northern outfall sewers, if running full, would bring down in 2·8 hours.

7835. (*Chairman.*) So that there would be an overflow or an outlet for the rest of the 12 hours?—Yes, assuming the sewer was still running full.

7836. But there is a period when it does not run full?—There would be periods when it did not run full.

7837. (*Sir John Coode.*) Assuming the sewers were all running full?—Assuming the northern outfall sewers bring to the reservoir all they can, then the reservoir would only hold that quantity of sewage for 2·8 hours, and upon the south side they would fill in $3\frac{1}{3}$ hours.

7838. (*Chairman.*) You mean that there are periods in the 24 hours when the flow of sewage is small comparatively?—There are.

7839. How much of the whole day of 24 hours would the reservoirs hold?—That would all depend upon whether there was rain or not.

7840. If there were not?—If there were no rain, then I have already pointed out that in nine hours upon the south side (we know nothing as to the north) one-half of the sewage would flow into the reservoir.

7841. Why in nine hours?—Owing to that fluctuation of the flow.

7842. Would that fill it?—Upon the south side it would more than fill the reservoir, with the present population.

7843. If that were the worst, they could then open their sluices and let it out, could they not?—That is no doubt what they do.

7844. Then there would not be an overflow there?—They may let it out by means of self-acting overflows, or they may open the sluices or pump it out.

7845. The reservoir would be capable of holding the sewage until it was time to discharge it?—There are provisions made, in case of the reservoir getting full, that it shall overflow into the river.

7846. What I mean is that, if it takes nine hours to fill it in dry weather, then the discharging process begins, because three hours out of the ebb would be sufficient to empty it?—Three hours it would take; but still that quantity, with the present population taken at 8 cubic feet per head, more than fills the southern reservoir.

7847. In other words, they are obliged to let it out before they would let it out if they could help it?—The reservoirs are too small for the present population, and therefore they cannot retain it.

7848. Cannot they let it out during the whole of the ebb?—If they did, the last that went out would come up again 12 miles above the outfall.

7849. Do you know how long, as a fact, before the beginning of flood tide they stop the outflow?—It is given in evidence that it is four hours after high water. My observations tended to show that it must be three hours, because upon many occasions the level of the water would not fall sufficiently low to enable them to empty the reservoirs until that three hours had elapsed.

7850. (*Mr. Lumley Smith.* The water in the Thames does not sink to the level of the outfall until three hours after high water?—Not until three hours after high water.

7851. With regard to the levels of the outfall, have you any observations to make upon the actual level?—I have already drawn attention to the question of mean tide level.

7852. Is that summed up in the conclusion you have come to that it would generally be three hours after high water before the water sank to the level of the reservoir?—Yes, I find some evidence given by Sir Joseph Bazalgette upon this inquiry at questions Nos. 56 and 57, which, if correct, show the mean tide level to be 2 feet $5\frac{1}{2}$ inches instead of 1·56 above datum the figure he has given.

7853. (*Chairman.*) Is the mouth of the outfall of the sewer into the reservoir below the level of high water?—It is somewhat below high water; the invert is put down at 11·4, but they lose that fall by letting it into the reservoir, the floor of which is only 2·75 above datum; and you recollect, from the evidence which was given in the original tidal observations it was insisted upon as a point of great importance that the level of the outfall should be 9 feet above ordnance datum.

7854. The height of the water in the reservoir is never higher than the mouth of the sewer, otherwise it would be penned back, up the sewer?—It may be so.

7855. But it is not meant to be so?—No; for this reason, that the sewers are 9 feet high, and if you add 9 feet to 11·4, that would bring you to 20·4 above ordnance datum. Now Trinity high water is 12·5 feet above datum, so that, though it is above the invert, high water would not be above the crown of the sewer upon any occasion. I was going to observe also that in the Report of Messrs. Hawksley and Bidder of the 6th of April 1858 they point out that the level of the outfall ought to be 10 feet above ordnance datum. In the original scheme of the Metropolitan Board of Works (that is, the scheme proposed by Sir Joseph Bazalgette and Col. Haywood), these reservoirs were intended to be made in a totally different way. They were intended to be made by enlarging the lower portion of the sewers themselves instead of making the reservoirs at a lower level than the sewers. I have no doubt in my own mind that these reservoirs were made with the object of treating

the sewage; and that accounts for the level and the mode in which they were constructed.

7856. (*Mr. Lumley Smith.*) By "treating the sewage" you mean chemically, or in some other way?—Yes; it is quite clear from the Reports of the engineers that they intended to treat the sewage at the outfall, especially in the summer months.

7857. (*Chairman.*) Is the bottom of the reservoir at a lower level than what you may call the lower lip of the sewer?—Many feet.

7858. You could build up the sides of the reservoir, and that would become a matter immaterial, would it not?—No; because they have put the reservoir below the level of the sewer.

7859. If the sewer runs into the reservoir, and if you build the walls high enough, you will have still the sewer underneath the walls of the reservoir?—But the reservoir is made at a different level of several feet, and the great object is to discharge the sewage upon the top of the tide, but owing to having put the level of the floor so low it cannot fully discharge until three hours after high water, and cannot be discharged so readily as if it had been at a level of 10 feet.

7860. If you could raise it bodily up, that would be obvious; but suppose you leave the floor where it is, you never empty it; but it would not matter much, would it, if there were a quantity always in it?—Yes; that mass of matter which could not be got rid of would undergo putrefaction and make the sewage more offensive than it is at present.

(*Mr. Bidder.*) We do empty it to the bottom.

(*Chairman.*) I understand the witness to say that the floor of the reservoir is so low that you cannot avail yourself of the whole of the ebb.

(*Mr. Bidder.*) It is not quite so; it would be more accurate to say that the floor is at such a level that you cannot finish your discharge until half ebb.

7861. (*Chairman.*) Then, I ask, why cannot you obviate that by raising the floor? Could you obviate it by raising the floor?—If you made the reservoir upon a higher level altogether, you could.

7862. Could the sewers then flow into it, or would they be too low to flow into it? If you raised the water in the reservoir, would there be an injudicious penning back of the water up the sewer?—It is quite possible that there might be, and that it would require an enlargement of the discharging capacity of the sewer to obviate that.

7863. Would the gorging of the sewers be objectionable?—It would be, but that could be got over, because the fall in a sewer does not really depend upon the fall of the invert; it is the fall of the surface of the water. As long as we can maintain a sufficient fall of the surface of the water to give sufficient discharging capacity to keep the sewer clear, that could be got over.

7864. It is not an open sewer at the top, is it?—No, it is arched over all the way.

7865. (*Mr. Lumley Smith.*) Merely increasing the area of the reservior would not diminish the defects arising from the depth of the level?—No.

7866. Do you know how long, having regard to the levels, it would take to discharge what is left in the reservoirs after the tide gets to the level of the bottom of the floor?

(*Mr. Bidder.*) The floor of the reservoir is one foot above half tide level, therefore it comes down to the floor before three hours ebb.

(*Chairman.*) Therefore one would think you could empty it in the first three hours of the ebb.

(*Mr. Bidder.*) So we can.

7867. (*Mr. Lumley Smith to the witness.*) I understand that that is not your view.

(*Chairman.*) I thought it was admitted that they could not empty it in the first three hours of the ebb.

(*Witness.*) At questions 57 and 58 evidence is given as to four hours being occupied in the discharge.

7868. (*Mr. Lumley Smith to the witness.*) You have taken from your observations the exact mean half tide?—I say that these observations in Sir Joseph Bazalgette's evidence with regard to the half tide are incorrect.

7869. (*Mr. Bidder.*) Your Lordship will find that Sir Joseph Bazalgette has given the figures; he says "the "bottom of the reservoir is +2·75 feet, or 1·19 feet "above half tide." Will you indicate which of those figures, if any of them, are wrong, and how?—I am going to do so. In answer to question No. 56 it is stated that, "Trinity high water is 12 feet 5 inches "above Ordnance datum; low water is 7 feet 6 inches "below datum." I mean to say, that if you take the mean of those two it shows that the mean half tide level is 2 feet 5½ inches above Ordnance datum. Now I have pointed out already from the observations we have made in the river that we make the mean half tide level nearly 2 feet at this point, which agrees within half an inch with this diagram No. 9. in the engineers' reports of the 6th April 1858.

7870. (*Mr. Bidder.*) Trinity high water, which Sir Joseph Bazalgette gives in answer to question No. 56, is a creature of Parliament, I think; it is a thing fixed by statute, and does not necessarily show what the real facts are?—But this is not a thing created by statute.

(*Chairman.*) That is so. Trinity high water is an arbitrary point fixed by law.

(*Mr. Lumley Smith.*) And that makes Sir Joseph Bazalgette's evidence less valuable to us, because it is dealing with a hypothetical standard.

(*Witness.*) Mean high water is shown at 11 feet above Ordnance datum upon this diagram, and mean low water at 7 feet below Ordnance datum, and half tide at 1·5. Now, anyone who calculates the mean between these figures, will see that the mean level of half-tide ought to be 2 feet and not 1·5.

7871. What is the practical result with regard to the position of the outfall in reference to mean half tides?—We know from the Crossness observations, where they have given us the level inside and outside the reservoir during the discharge, that there is always a considerable difference between the level inside and outside the reservoir, so that the reservoir practically never can empty until half tide level.

7872. (*Chairman.*) You mean they cannot finish emptying?—That is so.

7873. (*Mr. Lumley Smith.*) When it gets to the level what is left in the reservoir; is it all empty then, or is there still more left?—It may empty; the passages from the reservoir are sufficiently capacious to empty it.

7874. Your practical result is that it would empty itself at the half tide?—Yes. I may here point out another fact, which is also important in relation to the discharging of the reservoir, that in Mr. Rawlinson's inquiry, which was held at Barking, the gentleman in charge of these reservoirs gave evidence stating that the time during which discharging could take place was three hours, and sometimes three and a half hours; that is Mr. Cooper's evidence.

(*Mr. Bidder.*) I do not know who Mr. Cooper was; he may have been right or he may have been wrong.

(*Witness.*) He was the Metropolitan Board of Works engineer.

7875. (*Mr. Lumley Smith.*) I will pass on now to another matter. I believe you have calculated, have you not, the amount of actual solid matter that is every year discharged into the river Thames from the metropolitan sewage?—I have.

(*Mr. Bidder.*) Do you mean from the sewers?

7876. (*Mr. Lumley Smith.*) From the sewers. (*To the witness.*) Now your first calculation is based, is it not, upon an experiment which you mentioned last Tuesday in answer to question 7434, made by the Metropolitan Board of Works, as to the A B C process? Upon that experiment you base your calculation with regard to the quantity of solid matter which goes into the Thames?—Yes, that is one way in which I have estimated it.

7877. The A B C process, as I understand, is a process of treating sewage with certain matters, such as alum, blood, and clay?—Yes.

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

7878. For the purpose of seeing if it could be made into useful manure?—The materials in this case I believe were sulphate of alumina, charcoal, and clay, with a little blood and lime occasionally.

7879. I will ask you a little more in detail with regard to that experiment, because I do not think my learned friend agreed with the conclusion at which you arrived. The experiment was made by the Metropolitan Board of Works in 1872, that is to say, it was made by the Native Guano Company with the sanction of the Metropolitan Board of Works?—That experiment was carried out at the cost of the Native Guano Company, but under the direct control of the officers of the Metropolitan Board of Works.

7880. I should like, with his Lordship's permission, to have upon the notes the way in which you arrive by that experiment at the quantity of the solid matter in the sewage. This was an experiment made for the purpose of seeing what amount of solid matter was in the sewage, and what amount of manure could be produced?—It was an experiment made, I presume, both to test the purifying result of the process and the amount of manure produced.

7881. I believe at that time there were treated a number of gallons of sewage. Can you give me the number of gallons that were treated?—It is given in the report. I have the original report of the Metropolitan Board of Works here.

7882. Will you just give me the actual number of gallons?—At page 4 of Sir Joseph Bazalgette's Report of the 11th January 1873, the actual number of gallons of sewage experimented upon is stated to be 11,672,737, being $\frac{1}{343}$rd of the average flow of the sewage discharged at Crossness, and $\frac{1}{686}$th of the sewage of London.

7883. Now, will you tell me what was done. I believe to the sewage was added a quantity of dry materials?—Yes.

7884. How much was added?—The material was not added in a dry state, it was added in a wet state; but it was equivalent to 81 tons of dry material, according to the report.

7885. That was added to the sewage?—That was added to the sewage—that was the dry material of the A B C mixture.

7886. What did that produce?—It produced 142 tons of manure.

7887. How much of those 142 tons of manure was found to consist of water?—26·45 per cent.

7888. Then, when you deduct the quantity of water from the manure you retain, how much do you get of dry matter?—The amount of dry matter left was 104·441 tons.

7889. That you have got by adding 81 tons of dry matter, do you find that any portion of the 81 tons is passed away in effluent water?—Yes.

7890. Can you tell me how much of the 81 tons has gone away, and how that is arrived at?—Mr. Keates gives an analysis of the effluent water and also of the sewage, and by adding up from page 16 the total quantities of matter in solution in the raw sewage, it is shown that there were 72 grains of matter in solution in a gallon of the raw sewage.

7891. Those were salts in solution in the sewage?—Yes.

7892. But in the effluent water how much did you find in solution?—In the effluent water they give the figure at 98·70 grains.

7893. Therefore the difference between those two in the effluent water must have come from the dry material?—Yes.

(*Chairman.*) Are you not a little cross-examining your own witness, as it were; had you not better ask him what his conclusions are at once, and then if the other side have a mind to cross-examine, let them; you might, perhaps, ask the witness whether he could tell what quantity of solids were found in a given portion.

7894. (*Mr. Lumley Smith.*) How much, therefore, do you have to add to the 104·441 tons of dry material in the sewage to show what solid matter was taken from the sewage?—19·87 tons require to be added to the 104 tons, and then you have to deduct the 81 tons of the original A B C mixture, and you then have 43·31 tons of solids in suspension, a result equal to 57 grains in a gallon.

7895. If you multiply that by 686, how much do you get in 80 days?—You get 29,610 tons in the 80 days, and that in that same year it would be equal to 135,096 tons.

7896. Then all that solid matter goes into the river in one year?—Yes, all that solid matter goes into the river in one year from the sewers.

7897. (*Mr. Bidder.*) That is in suspension?—Yes, that is in suspension; that was in 1872. At the present time, allowing for the increase of population, and taking the sewage which has been given to us as 148,163,267 gallons per day, it shows that the quantity of solid matter going into the river is at the rate of 197,647 tons per annum.

7898. That is making correction for increased population?—Yes.

7899. (*Mr. Lumley Smith.*) That assumes that the A B C experiment was a fair test?—Yes.

7900. Is there any reason for thinking that at that time the solid materials were in excess or below the usual amount?—The report says that the sewage was abnormally weak, and from what I have stated of there having been so many more gallons per head of water leakage upon the south than upon the north, there is every reason to believe that it is under-estimated if it were applied to the whole of the metropolis; but I have taken that as the basis of calculation for the whole of the metropolis, and the quantity passing into the river as the quantity passing into the river in the year.

7901. This matter is partly fœcal matter and partly detritus of roads and so on?—It is.

7902. Have you made an estimate at all for the purpose of seeing what would probably be the amount of fœcal matter contained in the sewage as compared with the amount of road scrapings and other matters?—It is probably hardly worth while taking the solid part of the sewage of the population, because some part of the matter is always in solution; but I have taken other modes of arriving at the quantity. For example, we know that the amount of dry matter produced by the population is $3\frac{1}{2}$ ounces per head per day of the population. And of that a part would be in solution, so it would not be fair to assume that as all being in suspension; but there are other matters in addition to the fœcal matter which would take the place of that in solution, so that would not be a very unfair estimate of the solid contents contributed by the population to the sewers. Taking $3\frac{1}{2}$ ounces per head upon the 3,894,028 population it comes to 380·27 tons per day, which would be equal to 138,789½ tons in the year.

7903. Then by this ordinary estimate the dry matter per head comes to roughly 138,000 tons. How do you explain the difference between the 138,000 tons which you get in that way and the 198,000 tons that you get by your A B C experiment?—There would be very much of other solid matter going into the sewers. I have made experiments at Croydon with regard to the solid matter there, and we found that by passing it through a quarter of an inch grating one half of the solid matter in suspension is removed, one half goes to the sewage farm, and one half is removed, one-tenth of a pound per head per day is removed by extractors, and one-tenth of a pound per head per day goes on to the farm; so I find that the solid matter in suspension is one-fifth of a pound per head per day.

7904. (*Dr. De Chaumont.*) When you speak of $3\frac{1}{2}$ ounces of solid matter you mean all the water being drawn off?—Yes.

7905. (*Mr. Lumley Smith.*) Do I understand that the difference between the 138,000 tons and the 197,000 tons of the A B C experiment is due to the road scrapings and other foreign matter?—It is due to the road scrapings and other foreign matter. As I

have already pointed out in the case of Croydon, the roads do not drain into the sewers, but if you take one-fifth of a pound per head it is not very different from the 3½ ounces.

7906. So that your view is that of fæcal matter alone you get 138,000 tons, and of general solid matter 197,000 tons?—Yes; in the case of the A B C experiments, roundly, 200,000 tons in the year.

7907. With regard to this solid matter, you do find in the report of Messrs. Bidder, Hawksley, and Bazalgette, of 1858, at page 74, an estimate given, do you not?—Yes.

7908. What do you find is the estimate given in 1858?—I find that 250 tons a day are estimated as the amount of solid matter passed into the river; that was taken at 91,250 tons in the year.

7909. The population has increased from how many in 1857?—The population has increased from about 2,685,000 in 1857 to 3,894,000 in 1882.

7910. So that at the same rate what would the solid matter now be per day?—At the same rate the solid matter would now be 362½ tons per day, or in a year 132,312 tons.

7911. That agrees pretty nearly with the result you have got by taking the 3½ ounces?—Yes, or by taking one-fifth of a pound per head per day.

7912. Now a question upon a matter which stands by itself. I believe that the Beckton Gasworks outfall sewer, of which we have heard occasionally, has been gauged by you, has it not?—Yes. I made inquiries with regard to the Beckton Gas outfall, and I found that it was constructed in 1874, or 10 years after the northern outfall sewer had come into operation. I have had the quantity of sewage or water which flows out of it gauged, and I found that, on the average of nine days, the total quantity of water flowing out of it was 32·55 cubic feet a minute, or 292,952 gallons per day; or, if you take it in cubic feet, 46,872 cubic feet per day; that is the average of nine days, gauging night and day.

7913. (*Chairman.*) Has that a separate outlet into the river?—It has.

7914. By what law is that?—Anyone can have an outlet into the river for drainage purposes, provided he does not pollute the river. In this case, at Beckton, they have a reservoir for purifying the sewage; it is purified through coke, and very carefully treated, so that no solid matter goes into the river; but the water smells very strongly of gas.

7915. (*Colonel Ewart.*) Does that bring any sewage except the sewage of the gasworks?—There are 101 cottages upon the gasworks property, and it drains them.

7916. (*Sir John Coode.*) But did you not say that the solids were all filtered out?—Yes; there are purifying tanks, and there is a man always looking after them. Samples of water have been taken by our chemist for the purpose of analysis, and no doubt will be produced before you.

7917. (*Mr. Lumley Smith.*) With regard to the effect of taking the sewage of London to the outfalls at Barking and Crossness instead of discharging it, as it used to be discharged, in London proper, would that, in your judgment, have any effect upon the water or upon the tides in the river?—Yes.

7918. What is your view about it? The result is this, is it not, that the water which is supplied by the water companies to London, instead of being discharged into the Thames in London, is discharged now at Crossness and Barking, is it not?—Yes.

7919. The water which is supplied to the houses passes out into the sewers, and goes out into the river at a lower point than it formerly did; is that so?—Yes.

7920. What is likely, in your judgment, to be the result of that?—From this table, prepared by Mr. Mansergh, which I will now hand in, it will be seen that, by deducting the volume of fresh water entering the river at Teddington, you get the quantity of tidal water entering the river, and whether there is a large quantity or small quantity coming down, there is very little difference in the tidal capacity; that being so, it is clear that the effect of moving a large body of water from the upper part of the river and discharging it in the lower part is, as it were, to create a vacuity in the upper part, and then, when the tide begins to flow up, there is a certain tendency for the tide to occupy that position which had hitherto been occupied by the water which had flowed down the river; so that the effect of moving the outfalls to these points was really also to create a tendency for the tidal water to bring the sewage back again.

*The table was handed in, and is as follows:—*

TABLE of CAPACITY of RIVER THAMES. Prepared by Mr. JAMES MANSERGH, M. Inst. C.E.

To which has been added the Volume of Fresh Water entering the River.

| | Two Days after High Water Spring Tide. | Two Days after High Water Spring Tide. | Neap Tide. | Neap Tide. |
|---|---|---|---|---|
| Tidal water above synchro-surface lines, Teddington to Southend | 1st Oct. 9h. 28m. A.M. to 3h. 8m. P.M. | 30th Oct. 9h. 20m. P.M. to 3h. 15m. A.M. 31st | 6th Oct. 1h. 7m. A.M. to 7h. 37m. A.M. | 4th Nov. 1h. 0m. A.M. to 7h. 10m. A.M. |
| | Cube feet. 20,296,232,680 | Cube feet. 20,598,501,011 | Cube feet. 10,914,013,084 | Cube feet. 10,496,748,630 |
| Volume of fresh water entering river | 61,400,087 | 462,893,020 | 55,855,800 | 262,216,780 |
| Tidal water entering river | 20,234,832,593 | 20,135,607,991 | 10,858,157,284 | 10,234,531,850 |
| Tidal water above synchro-surface lines, Barking to Southend | 18,576,054,395 | 18,905,450,703 | 9,888,777,284 | 9,476,250,993 |
| Low-water content Barking to Southend | 17,736,971,361 | 17,433,521,276 | 21,551,899,564 | 19,539,139,333 |
| Total content of river, Barking to Southend | 36,313,025,756 | 36,338,971,979 | 31,440,676,848 | 29,015,390,326 |

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

7921. (*Chairman.*) What proportion is the supply of the water companies compared with the fall over Teddington Lock?—It varies immensely; in a dry period it would not be more than a fourth part of it.

(*Mr. Bidder.*) It is about an eighth upon the average. I took that from the witness's own statements.

7922. (*Chairman.*) I do not know whether it is worth noticing that the New River and the River Lea are great suppliers?—The River Lea in dry weather has very little water coming down it; it is all taken by the water companies.

7923. (*Chairman.*) It flows out at Blackwall?—Yes; but formerly it was distributed in other parts as well, by the water companies.

(*Mr. Lumley Smith.*) The New River does not get into the Thames.

(*Witness.*) The present water supply, by which I am speaking of that taken from the Lea as well as from the Thames, would not be a third in dry weather of what comes, over Teddington Lock; it is about 149,000,000 gallons a day; that was in 1881 the total average daily supply from all sources.

7924. (*Prof. Williamson.*) Apart from the quantities, I should like to understand what you mean exactly by the statement you have just made, that the fact of sewage being discharged lower down the river caused the sewage to go up higher?—That same volume previously filled the channel of the river when it was put in higher up; but taking that down to a lower point and holding it to a certain period of the tide, has created a vacuity in this upper part.

7925. And there is not so much poured in higher up?—It was formerly poured in all the way up the banks, but it is now only discharged upon the ebb tide, and therefore there is no discharge taking place to fill this upper part of the channel, so that the channel having been robbed of a portion of its water, a greater amount of tidal water must come in to fill its place.

7926. Some of the sewage is brought up by the tide instead of being poured in direct?—So much more comes up.

7927. But that cannot be so much as if it had been poured in straight.

7928. (*Chairman.*) Suppose that by some contrivance they diverted a fourth of the water that comes over Teddington Lock, and it never came into the river at all, then you say the tidal water would come higher up?—The tidal water would fill up that vacuity.

7929. But, practically, if they discharge it at a lower place, it comes up still more?—It comes up still more, because it has a tendency to create an artificial flood at that point, and it flows up still further.

(*Mr. Bidder.*) If that argument be correct, it points out that we ought to revert to the old state of things.

(*Witness.*) In this particular report of 1858 my attention was directed to the amount of solid matter which used in 1857 to be found at various points of the river, and our chemists will show you that it gets up to a much higher point than it previously used to do, which is a corroboration of what I have been stating.

7930. (*Mr. Lumley Smith.*) The next table you have to produce is a table of the proportion of death-rate annually at Barking town, Essex, and other places?—Yes.

7931. How have you obtained those?—Those are the actual figures taken from the quarterly returns of the Registrar General.

7932. You have them at Barking town, at Grays, at Dartford, and at Gravesend?—Yes; but I must point out that those are the registration districts which comprise more than the towns themselves; those are the districts abutting upon the Thames. Dartford includes Erith and all that district, and so with Gravesend; those are the actual registration districts.

*The tables were handed in, and are as follows:—*

POPULATION and DEATH RATES ANNUALLY at BARKING TOWN, ESSEX.

| Year. | Population on 30th June. | Births and Deaths. | | | Rates per Thousand. | | | |
|---|---|---|---|---|---|---|---|---|
| | | Births. | Total Deaths. | Zymotic Deaths. | Rate of Births. | Rate of Total Deaths. | Rate of Zymotic Deaths. | Births divided by Deaths. |
| 1871 | 6,627 | 236 | 110 | 16 | 35·61 | 16·60 | 2·41 | 2·14 |
| 1872 | 6,850 | 286 | 156 | 47 | 41·75 | 22·77 | 6·86 | 1·83 |
| 1873 | 7,080 | 303 | 140 | 15 | 42·80 | 19·77 | 2·12 | 2·16 |
| 1874 | 7,319 | 297 | 139 | 11 | 40·58 | 18·99 | 1·50 | 2·14 |
| 1875 | 7,565 | 307 | 190 | 43 | 40·58 | 25·12 | 5·68 | 1·62 |

POPULATION and DEATH RATES ANNUALLY at GRAVESEND, KENT.

| Year. | Population on 30th June. | Births and Deaths. | | | Rates per Thousand. | | | |
|---|---|---|---|---|---|---|---|---|
| | | Births. | Total Deaths. | Zymotic Deaths. | Rate of Births. | Rate of Total Deaths. | Rate of Zymotic Deaths. | Births divided by Deaths. |
| 1871 | 21,303 | 639 | 381 | 48 | 30·00 | 17·89 | 2·25 | 1·68 |
| 1872 | 21,506 | 638 | 407 | 56 | 29·67 | 18·92 | 2·60 | 1·57 |
| 1873 | 21,712 | 588 | 419 | 41 | 27·08 | 19·30 | 1·89 | 1·40 |
| 1874 | 21,920 | 646 | 466 | 55 | 29·47 | 21·26 | 2·51 | 1·39 |
| 1875 | 22,129 | 632 | 455 | 71 | 28·56 | 20·56 | 3·21 | 1·39 |
| 1876 | 22,340 | 718 | 401 | 81 | 32·14 | 17·95 | 3·63 | 1·79 |
| 1877 | 22,554 | 706 | 465 | 98 | 31·30 | 20·62 | 4·34 | 1·52 |
| 1878 | 22,769 | 704 | 504 | 107 | 30·92 | 22·14 | 4·70 | 1·40 |
| 1879 | 22,986 | 698 | 382 | 35 | 30·37 | 16·62 | 1·52 | 1·83 |
| 1880 | 23,206 | 686 | 411 | 50 | 29·56 | 17·71 | 2·15 | 1·67 |
| 1881 | 23,428 | 669 | 408 | 58 | 28·56 | 17·42 | 2·48 | 1·64 |
| | | | | | | | | 1·57 |

7933. Do those give us the actual figures, and do you draw any conclusions from them which you desire to bring to the attention of the Commission?—Yes. I think the figures show considerable fluctuations in the death-rate which are not really consonant with very healthy districts. There are some districts at times which have a marked degree of health.

7934. I see it varies very much in the column showing the deaths from zymotic diseases?—The most unhealthy district of all, in my opinion, is shown to be Erith—that is, the Dartford district—when tested in a particular way. The way in which I look at them is, by comparing the birth-rate as it affects the death-rate; if you divide the births by the deaths it gives you a better result of the state of health in the way of gain to the country than the actual death-rate. Out of the total number of births a very large proportion of deaths takes place, perhaps 25 per cent. in the first year, and where there is a large birth-rate, it materially affects the death-rate; therefore I say that if you simply divide the births by the deaths it will show you what was the gain to the country in any particular district, and treating these districts in that way it puts a very different complexion upon some of these places.

7935. (*Mr. Bidder.*) We have the births divided by the deaths; that is a fraction?—Whenever the number is above two you may say the place is healthy; if it falls under double the death-rate, then you may say in proportion as it falls under that it is unhealthy.

7936. Is a place unhealthy or healthier in proportion as the fraction gets bigger or smaller?

7936*a*. (*Chairman.*) The witness says if you divide by two it is an average condition of health?—It is a good condition of health.

7937. But if it would divide by three it would be wonderfully good?

(*Mr. Bidder.*) That is to say, if the births were three times the number of the deaths.

(*Witness.*) That would be too much to expect.

7938. (*Chairman.*) The larger the proportion by which you can divide the healthier the district?—Yes.

7939. (*Dr. Stevenson.*) What is the proportion you take as the health range?—Two.

7940. The births ought to be twice as numerous as the deaths?—Yes.

7941. (*Mr. Lumley Smith.*) And having regard to the births and deaths of those four places, do you consider them healthy or unhealthy?—The general conclusion I draw with regard to some of those districts is that they are not in a very good sanitary condition.

7942. I understand your view to be that the fluctuations show that they are not healthy places?—The fluctuations show that they are not healthy places. If you take any one of the years having a high zymotic death-rate, and divide the births by the deaths, it will at once show a lower number in the unhealthy period, and corroborate the rate of mortality.

7943. (*Chairman.*) Why have you taken Grays?—Grays is the registration district which includes the districts of Grays and Thurrock, districts upon the river.

7944. (*Mr. Lumley Smith.*) Now, passing from that to another matter, in your judgment is the discharge of the sewage into the river Thames in any way likely to affect the wells in the neighbourhood?—Yes, it is.

7945. Will you tell us, if you please, what opportunity you have had of testing the effect of the sewage upon the wells. I believe you had to examine, had you not, the neighbourhood of the river with a view to sinking wells?—In 1878, when the Metropolitan Board of Works proposed to supply London with water from the chalk formation, I was engaged in making an investigation of all the sites which they had chosen for the purpose of water supply, and one of those sites was at Grays, in Essex, within half a mile of the bank of the river.

7946. How far is that below the outfalls?

[*The site was pointed out to the Commission.*]

7947. You investigated, did you not, those sites?—I investigated those sites in 1878, at least, that particular site amongst others.

7948. The Thames at that part is flowing through a chalk formation, is it not?—The Thames at that spot is flowing through the chalk.

7949. There is a well, is there not, at the Grays chalk quarries?—Yes, there are a number of wells there.

7950. Was that the place at which the Metropolitan Board of Works proposed to draw their supply?—At that site.

7951. For that purpose did you examine what the nature of the water was in the wells?—Yes. I had samples of water taken from that place, and also at Erith, and submitted to our chemist.

7952. (*Mr. Bidder.*) Where did you have samples taken at Erith?—We have had samples of water taken from the Essex Water Company's works, and from the "Green Man and Bell" well at Grays.

7953. (*Mr. Lumley Smith.*) Samples were taken at Grays, I understand?—Those wells are at Grays.

7954. Were those all that were examined?—No; those that I have just referred to were samples of water amongst other samples which have been drawn recently, in December last. But in 1878 I caused the levels of the water in all the wells in this neighbourhood to be taken, and it was found that from the pumping which was going on in those quarries at that time, and from other pumping in the neighbourhood, all the water fell to the direction of the point of exhaustion. At that point the river Thames runs through the chalk, and we found that there was a direct flow from the direction of the Thames itself (which at that point has received the metropolitan sewage) towards this spot, which was proposed to be selected for the purpose of supplying London with water.

7955. (*Sir John Coode.*) About how far is that from the direct line of the margin of the river?—The chalk quarries pumping station is a mile distant from the river.

7956. (*Chairman.*) Who was pumping there, and why were they pumping?—In order to get at the bottom of the chalk quarry, and to keep the water down it is necessary to pump, and it is found that the pumping at this particular quarry affects the water for miles round. I have ascertained most clearly that the pumping at this quarry affected some ditches a mile and a half distant from the quarry in which watercress was grown; so much so that the occupier of them, a man named Benjamin Wood, commenced proceedings against the company for compensation for the effect of their works upon these watercress beds. He commenced the proceedings.

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

(*Mr. Bidder.*) But he did not bring them to a successful issue.

(*Chairman.*) He found that there was a case of Chasemore and Richards which showed that the action was not maintainable.

(*Witness.*) Then, again, there are other quarries in the neighbourhood—there is Messrs. Gibbs' chalk quarry; it is found that when they come to pump at the quarries at Grays they can lower the water immediately in Messrs. Gibbs' quarry, which is some considerable distance from them.

7957. (*Sir John Coode.*) How far is that from them?—One mile.

7958. Do you say the effect is felt immediately?—Almost immediately; within a very short time. Then we have had the waters of these Essex waterworks and the "Green Man" well analysed, and we find that they contain very much more chlorine than was originally the case when the pumping was not going on; in fact, from a published statement made some years ago with regard to the same quarries, it was shown that the amount of chlorine was 1·4 per gallon. In the analysis made upon the 17th of September 1860 by Dundas Thompson, M.D., F.R.S., it was shown that the amount of chloride of sodium was 2·33 grains in a gallon. Now we find that the quantity of chlorine varies with the state of the tide, there being a somewhat larger quantity at high water than at low water.

7959. (*Mr. Bidder.*) What is the quantity?—The quantity is 13·6 parts of chlorine, not chloride of sodium, in 100,000 parts, the normal quantity of the district being 1·4 in 100,000 parts. From that, and using the formula which I followed out the other day, we are able to arrive at the number of volumes of river water or tidal water, for which we have the analysis of the tidal water in the Thames opposite the works. We find that there are about 20 gallons in every 1,000 of water which had come from the river, that is, at high water. On the average of all, taking the three experiments, high tide, mid tide, and low water, we have 23 gallons of river water mixed with 1,000 gallons of the normal water of the district. The testing of the well at the "Green Man and Bell" shows that there is 25 gallons of river water in 1,000 gallons. I think I ought to have said upon a former occasion that the formula I introduced for the mixing was really due to Dr. Frankland, as it was submitted to us by Dr. Frankland, and has been carefully examined to see whether it was correct or not.

7960. (*Mr. Lumley Smith.*) The result of that is that the tidal water gets into the chalk wells near the river, and if there is sewage in the tidal water that will get there also?—Yes, assuming, of course, that all the chlorine comes from the river. In the case of Grays it is difficult to see where else it could come from, as it is not a populated district where there are cesspools. There might be a doubt in the case of Erith; but in the case of Erith, a well at Crown Cottages, in Cross Street, leading out of Pier Street, Erith, contained 10·8 parts of chlorine in 100,000; that was taken at near low water, and at the same time the water in the Thames at low water contained 40·5 in 100,000 parts. That will show, compared with the low water of the Thames, that in every 1,000 gallons 322 were water coming from the river, that is, assuming all the chlorine comes from the river; that would be about a third of the whole, compared even with low water when the river is very fresh, owing to the large quantity of water coming down.

7961. (*Colonel Ewart.*) Is that taken near the inhabited part of Erith?—Yes. That was taken upon the 3rd of December 1882.

7962. (*Chairman.*) Is water containing that proportion of chlorine drinkable?—In soda water, I understand, there is a very much larger quantity than that.

7963. As I understand, judging from the chlorine it contained, one-third of the water in the well had been in the river?—That is upon the assumption that all the chlorine was due to the river. If part of the chlorine were due to the introduction of cesspool matter, that would introduce an error into it.

7964. Would not the river water have been brackish?—Not in that part of the river. But I know a town where the water contains as many grains of chlorine as the water of the river at low water did that day.

7965. But I understood you concluded, from taking a sample of the water in the well, that one-third of the water in the well had been in the river?—Comparing it with the known condition of the water opposite Erith on that particular day. There are wells upon the south coast of the country which contain that proportion of chlorine which are used for the supply of drinking water.

7966. (*Mr. Lumley Smith.*) Mr. Beaumont Morice, who has local knowledge, suggests that I should ask whether you know that any wells have been shut up?—I do not know that.

(*Mr. Bidder.*) We have a report which puts it in this way:—Cross Street; two wells; one said to be connected with cesspools; polluted.

(*Mr. Lumley Smith.*) In answer to Question 4,457 Dr. Jessett says:—"Last year we closed six or seven, "and we have closed, I suppose, every year, more or "less. I daresay we have closed six or seven wells "almost annually for four or five years past at any "rate."

7967. (*Chairman.*) Take the Grays wells. The evidence is that there is water which comes from the Thames. If water comes from the Thames it presumably contains sewage, because we know that sewage gets down there. If sewage water does come into those wells, then what next; is the water unhealthy?—It sometimes becomes, I should say, most undoubtedly so, and it has been already given in evidence to that effect.

7968. It is unpleasant to the taste, I presume?—It does not follow as a rule that it is so.

7969. Or to the smell?—Not at all as a rule. As a rule the worst waters are the most palatable; but it has been stated before this Commission that the water taken from this neighbourhood has been supplied to ships in which outbreaks of typhoid fever have occurred, and a witness made use of the expression that the source of supply needed to be investigated.

7970. Did he refer to Grays?—He did. It was Grays he alluded to as having supplied the ships in which the outbreaks of fever occurred.

7971. (*Prof. Williamson.*) Were any other constituents determined in the water except the chlorine?—No.

7972. Not the nitrates?—No.

7973. (*Dr. Stevenson.*) How long had the water been known to contain chlorine?—I know it was known in 1878. We know that in 1860 the waters were not salt, because there is a published analysis of the water of that date to which I have referred.

7974. (*Mr. Bidder.*) Where do you get the 1·4 in 1860?—It was a report made by the promoters of the water company.

7975. (*Mr. Bidder.*) Your evidence is based upon the statement that somebody in 1860, not yourself, analysed the water in a chalk well at Grays and found 1·4 of chlorine. I want to know where that is found?—I will have it referred to.

(*Mr. Beaumont Morice.*) May I mention, with regard to the wells at Erith, that one of the members of the Commission in the examination of Dr. Jessett, just before the case for the meriorialists concluded at Question 4,452, asked him this question, "Were the "cases of typhoid fever chiefly in the houses that had "tidal wells?" and he answered, "Yes, chiefly. It is "generally on account of cases of typhoid fever that "our attention has been drawn to the state of the "wells, and we have had the water analysed."

(*Chairman.*) If the well in question is near to cesspools, I do not think that becomes of so much importance.

(*Witness.*) I beg now to be allowed to draw the attention of the Commission to a Table No. 9 in
